Mr. B. WILLS RICHARDSON said that in the Adelaide Hospital they had had five cases of ovariotomy, four of which recovered, and as the question of adhesion had been raised, he might mention two of these cases. One occurred in the practice of Dr. Albert Walsh, and the other was under the care of Dr. Atthill. In Dr. Walsh's case, not only a piece of intestine, but a great many inches of intestine, were adherent to the sac, and they had to be torn off. The intestine and sac seemed more like the ox tongue than anything else he could resemble it to. That woman recovered without a bad symptom. In Dr. Atthill's case the sac was adherent to a portion of the anterior abdominal wall. It had, of course, to be torn off,, and in tearing it a considerable portion of the peritoneum was torn from the abdominal wall also, and after the sac had been removed the peritoneum was seen hanging in the abdomen like a flap, and it was cut off. The transverse muscle was exposed. Even that woman had not a bad symptom. Both of these cases, therefore, had recovered without a bad consequence, and in the latter case a considerable portion of the abdominal wall was stripped of its peritoneum.

Mr. TUFNELL said he just rose to mention a case illustrative of what Mr. Stokes had said, in which he had assisted the late Dr. Beatty. It was that of a young lady, and there was not the least difficulty. The wound was only about two inches in length, and yet in two hours she sank and died, and no reason whatever could be assigned for such a change. No post-mortem examination was made in the case.

Mr. RICHARDSON said, though it was somewhat out of order, he desired to ask Mr. Stokes whether the venous system was examined in his cases.

Mr. STOKES replied that the heart and pulmonary veins were examined.

Mr. CROLY said he was glad the subject had elicited so much interesting discussion. In the first ovariotomy case he had, he expected that there would have been a great number of adhesions, from the fact that the woman complained of intense pain over the region of the right ovary, and had so much crepitus. She required opium, leeches, and purgatives, and when these had been applied with good effect he performed ovariotomy. Very few adhesions were present, and it was an interesting fact to record that his hand was not once introduced into the cavity of the abdomen, which, as far as his limited experience of ovariotomy went, was an exceptional circumstance. After he punctured the cyst it drew out like a glove. The woman, however, died in 24 hours, and he confessed he was greatly disappointed, and was greatly at a loss to know the cause. There were no appearances to account for it, and the post-mortem examination revealed nothing. He agreed with Mr. Stokes when he said he thought there was no advantage gained by special nursing and special wards. He (Mr. Croly) was aware that adhesions were looked upon by some high authorities as no preventive of recovery. He did not question the point laid down by Mr. Keith as to the peritoneum undergoing change in these cases. It was quite possible that the portion of the peritoneum that had become adherent was changed. If he met with a case similar to Dr. Atthill's (at which he was present), no matter how formidable, he would take out the tumour as well as he could, and he did not think they should be discouraged by adhesions.

The Society then adjourned to the 24th of March.

Literature.

DR. CHUNDER ROY ON FEVER. (*a*)

OF late years it has been the fashion with writers, whether of fiction or reality, such as Disraeli, Bulwer, and others, to laud the Aryan race of the Himalayas, and, if any nation is entitled to the epithet, it is the Hindu root and branch. We have seen many talented Hindus, such as the late lamented Dr. Chuckerbutty, and others, educated in London; but it is interesting to know that Dr. Gopaul Chunder Roy is a scion of the Calcutta University School, that he was a practised teacher of medicine before he ever set foot on British soil, that subsequently he became a Fellow of the Royal College of Surgeons of London by examination, and M.D. of the University of Glasgow, and then qualified in the Government School of Military Medicine and Surgery, at Netley, for the Indian Service. Now Dr. Roy comes before us as the author of a valuable clinical contribution to our knowledge of fever, founded on extensive personal experience in a desolate region of India.

The sanitary statistics of Bengal are applicable to every part of the world, and interesting to every medical practitioner. The manner in which he has worked out the problem of endemic disease will be found suited to fever, whether intermittent, remittent, or continued, as found anywhere on the face of the globe, and he traces skilfully the conversion of endemic into epidemic disease.

The work contains a considerable addition to our knowledge of the physiology and pathology of the spleen, besides an excellent *résumé* of medical practice in India, none the worse for being concise. Dr. Chunder Roy is versed in all the medical literature of the day, and the controversies respecting malaria, chill, and moisture, contagion, bacteria, spores, and germinal cells, morbid poisons of variola, syphilis, and poisonous snake-bites. The discussion on malaria, and the remarks upon various articles of the materia medica are well worth consideration.

ON THE RARITY OF SOFT CHANCRE IN PARIS AT THE PRESENT TIME. (*b*)

DR. CHARLES MAURIAC is one of the physicians to the Hôpital du Midi of Paris, and is well known as an accomplished physician in other departments of pathology. His translation of Dr. West's work on Diseases of Women is so good that the author told us that when he brought out a new edition he would translate all

(*a*) "The Causes, Symptoms, and Treatment of Burdwan Fever, or the Epidemic Fever of Lower Bengal." By Gopaul Chunder Roy, M.D., F.R.C.S., Surg. Bengal Establishment. J. and A. Churchill, London. Thacker, Spink, and Co., Calcutta.

(*b*) "On the Rarity of Soft Chancre in Paris at the Present Time." By Dr. C. Mauriac.

Mauriac's notes. Such being the case, we are prepared to find that Dr. Mauriac is as an accomplished writer on the special and interesting topic before us.

Gonorrhœa has possibly been known to mankind in all ages, and it seems to the writer of this review that soft chancre is in the same category of virulent diseases, for Celsus, in his work on medicine, seems clearly to write about such kinds of sores. Syphilis is a new disease; it was unknown to the Ancients. It seems to us that this terrible contagion must have been brought to Europe by the sailors of Columbus' ships in the year 1493; notwithstanding that Fracastor and other able writers in the sixteenth century assert the contrary. We cannot find that the Greek or Roman writers knew anything about syphilis; and as to the Chinese, we confess we know too little about that curious people to hazard an opinion as to whether the works spoken of by Captain Dabry, and which would make out that Chinese medical men had described secondary and tertiary disease long before the Christian era, are authentic or not.

Can we do much to put an end to venereal diseases? That is the question which has puzzled so many able minds of late years. In reply to it Dr. Mauriac, of Paris, in his most interesting work, entitled "Rareté Actuelle du Chancre Simple," Paris, Delahaye, 1876, thus speaks: "The soft chancre is the most crapulous of the three venereal diseases. In truth, it is a disgrace to our civilisation that it still exists. Have we not the power of destroying it as we destroy vermin, and all parasitic diseases, which lodge on the skin? Yes, I am convinced that it will be made to disappear whenever society will seriously take the trouble to make it cease. Its rarity, which has been extraordinary for some time past, is it not perhaps the prelude of its future extinction?"

"Certainly (he adds) I would not be equally affirmative with respect to syphilis. Since that disease invaded Europe, at the end of the fifteenth century, it has never ceased to rage. It has before it, as it has had in its past history, many years of existence. Reason however, tells us that it is not inherent in humanity, so that we need not for ever despair to destroy it. But how many circumstances contribute to perpetuate it; its constitutional character, the contagiousness of its products during their early phases, the inutility of preventive cauterisations of its primitive accident, its hereditary transmission, and the virulent contagiosity of the lesions of the fœtus, &c."

"As to gonorrhœa, it will remain as long as humanity. It was born with it, and will die with it. Were we to extinguish this special inflammation for several years, it would reawaken from its ashes. And, indeed, it would be rapidly reawakened, for it would not be a very difficult or complicated experiment to create an acute catarrh of the urethra and raise it to that point of specificity that would make it contagious. Perhaps such a fact takes place more frequently than is supposed. Whereas, let anyone attempt to create anew the syphilitic poison or the virus of the simple chancre."

In a letter to the writer of this paper from Dr. Mauriac, dated January 31, 1875, that gentleman says: "I am a great partisan of the measures of repression used at Paris. It may perhaps be opposed to the principles of individual liberty, but it is extremely useful in the point of view of hygiene. It appears to me incontestable that, if we were to sequestrate all persons attacked with venereal contagion until they were completely cured, it is not to be doubted that we should arrest the propagation of the disease. That is the method the most simple, energetic, and radical. I do not say the most moral, or philosophical. Whatever the practical solution adopted may be, regulated repression, guided by curative, preventive, and hygienic medication, will always be of incontestable efficacy."

"But (adds M. Mauriac) in order to take away the reproach of injustice, first of all, it ought to be applied as rigorously, and even more rigorously, to men than to women. Therein lies the odious nature of the present law. Why do they imprison a poor woman who has infected without knowing it, and in order to gain her living, several individuals who have sought her but for their pleasure, whilst they leave in perfect liberty these same individuals who, having but their pleasures alone to satisfy, infect, without any scruple, women obliged to undergo their contact for a morsel of bread to eat."

"With an energetic repression, guided by medical science, and directed against *men* as well as women (says Dr. Mauriac), I think we should attain extraordinary results. But is this possible?"

Such are a few remarks from the able pen of Dr. Charles Mauriac, physician to the Hôpitul du Midi of Paris; and I now proceed to show what are the results of his long and important studies at that hospital as to the prevention of the different varieties of venereal disease in Paris. It appears, then, that, in 1869, 3,547 persons came to the Hôpital du Midi to consult Dr. Mauriac, and of these there were 680 syphilitic primitive affections; 503 of consecutive syphilitic symptoms; 1,633 cases of gonorrhœa; with 367 simple chancres. So that in 1869 there were nearly twice as many hard sores as soft sores. In 1875, as we shall see, the soft chancre was seen only some 55 times at his consultations, and Dr. Mauriac thus adds: "I was speaking on this question, some days ago, with one of the eminent masters of modern syphilography, with Dr. Bassereau, to whom we owe the great discovery of the duality of the chancre. I said to him that the rarity of the soft chancre was becoming more pronounced daily, so that whole months passed without my ever seeing one solitary case of it at my consultations."

Dr. Bassereau thereupon consulted his notes, and wrote to say that when he was *interne* of M. Ricord at the Midi there was found but one hard chancre to thirty soft chancres.

Very few chancres, either hard or soft, are treated at the Lourcine, female venereal hospital of Paris. Thus, in 1861, there were there treated 425 cases of vulvitis and vaginitis; 36 cases of indurated chancres; and 20 cases of soft sores.

The war and the Commune caused great disturbances in the amount and kind of venereal contagion seen by the medical officers of the Hôpital du Midi. Thus, in 1871, there were no less than 794 cases of soft sore and 247 cases of hard sore seen by M. Mauriac. In 1872, there were admitted into that hospital 914 cases of soft sore; 561 cases of hard sore; 704 of secondary syphilis; and 1,212 cases of gonorrhœa. In 1873 there were treated at this hospital 3,487 cases, of which 625 were soft sores; 548 were hard sores; 902 secondary syphilis; and 1,402 gonorrhœa. In the year 1874, Dr. Mauriac treated only 58 cases of soft sore; 372 cases of hard; 154 cases of secondary syphilis; and 504 cases of gonorrhœa in his 96 beds. In 1875, he treated 1,247 cases, out of which there were 55 cases of soft sore; 527 cases of syphilis, primary and secondary; and 665 cases of gonorrhœa. These were treated in his wards.

Dr. Mauriac, then, believes that at this moment there exist at Paris at least ten times as many syphilitic chancres as soft chancres; and he believes that a somewhat similar diminution is found to obtain at this time in Copenhagen, Christiania, Prague, Vienna, Munich, and Strasburg. Everywhere, he says, soft chancre is becoming less frequent; whilst hard sores are increasing in numbers. At Lyons, too, there are now so few soft sores that M. Brun, one of the *internes* of the hospital for venereal patients, said lately that he had not observed more than four or five soft sores in six months.

The soft sore is like an animal or vegetable parasite; it only acts locally; and when burnt out of the part its action ceases entirely. Syphilis, on the contrary, cannot be locally got rid of; and whilst the soft sore has *no* incubation, the hard one has an incubation of weeks, and even months. On these considerations, Dr. Mauriac asserts that the soft sore, he is profoundly convinced, is condemned to disap-

pear as soon as society thoroughly makes up its mind to make it disappear; and he points to the astonishing rarity of it as a proof of his assertion. Any person, too, on examination of the genital organs of either sex will easily notice this sore, with its edges sharply cut, and the surrounding inflammatory areola, and with the sanious pus exuding from it. This is not the case with the syphilitic sore, which causes infinitely less inflammation, and is often ignored, and, especially in women, remains in a latent state. Nine times out of ten, too, mucous tubercles, or condylomata, are taken by those who are ignorant of their nature for simple pimples caused by indigestion. Gonorrhœa, in its after stages, in the female, is undistinguishable, or nearly so. Add to these facts the painfulness of the soft sore as compared to that of gonorrhœa, or hard chancres, and it is easy to see why these sores are more readily recognised. He attributes the rarity of this form of venereal disease to the police medical system of Paris.

But here comes the weak side of the system. "Suppose a woman have, in place of a soft sore, a hard sore," says Dr. Mauriac (p. 72), "she will soon be cured of this. But then will come condylomata, which are almost as contagious as the primary disease; and these will be reproduced during a period of fifteen months, two years, and even more. Rendered back to liberty, she will be the focus of contamination without any new infection. For an absolute guarantee it would be necessary that her detention should last as long as the period of contagiosity of syphilis. Is this possible? It is the same with contagious catarrh of the genital organs in women. How many are there who are believed to be cured, and in whom the disease returns in a few days under the form of innocent leucorrhœa. If gonorrhœa be difficult to dry up in the male, it is yet more so in the female. We cannot, however, detain patients until all the secretions of the vulvo-urethral glands, of the vagina, and of the neck and body of the uterus may have attained a perfect type of normal health."

The following statistics show how truly Dr. Mauriac has spoken of the difficulty which there exists in getting rid of that great plague, syphilis, by any means yet tried in Paris. Whilst soft sore is becoming so rare, syphilis—true syphilis, is augmenting in Paris. Thus, in 1861, 570 cases of primary and secondary syphilis were treated at the Hôpital du Midi; in 1861, 572 cases; in 1862, 503 cases; in 1866, 799 cases; in 1868, 985 cases; in 1869, 1,442; in 1872, 1,265; and in 1874, 1,578 cases. The same holds good at the Hôpital Saint-Louis. M. Mauriac shows that clandestine prostitution is the cause of this great increase in syphilitic affections. "The downfall (he says) of public houses of prostitution, and of prostitution *en carte*—*i.e.*, of inscribed prostitution, and the increase of free or clandestine prostitution have, then, the double effect—first, of diminishing the soft sore; second, of augmenting syphilis.

It appears from the statistics given by Dr. Mauriac that soft chancres are, strange to say, relatively more commonly obtained among registered than among unregistered women in Paris. He makes this important remark, which may make many persons reflect:—"Remember that by the fact of women being under police control, they are no longer free; and these women are obliged to accept everyone, the most ignoble persons, the most filthy, and those least careful of their persons, and most degraded by nature. All of these have a resource in the public house of prostitution. Repulsed by the free women, or even by the *filles en carte*, they are obliged to content themselves with this slight satisfaction of the senses, which the women in houses cannot refuse when money is offered. The women in registered houses thus become the prey of all that is the most repulsive and least scrupulous amongst the lowest category of debauch and libertinage."

Alas! what terrible degradations and miseries yet haunt our modern societies! Wars are but of yesterday in Europe, and threaten again to break out between the most civilised peoples. Poverty and infantile deaths abound everywhere. Drunkenness and crime are still plentiful enough in our midst. And amid all of this stalks prostitution with its detestable *cortége* of venereal diseases. When will society learn to be able to attack such manifold evils justly and without tyrannising over the weak? Is there no way of, getting rid of venereal diseases except the French system—which seems so inadequate to cope with syphilis and gonorrhœa, and which leaves men free to infect for their pleasure as many women as they please, whilst it shuts up in a prison the woman who sells all she has to sell, her person, for a little food? Is it not possible to educate our population in the elements of hygiene, and make entrance into numerous charities simple for all men and women with "contagious diseases," whilst we punish with severity any one who knowingly infects any other with such contagions?

Such are one or two of the questions which suggest themselves to us on reading Dr. Mauriac's most philanthropic and kindly written work; and remembering that in Paris at least the effect of police regulations has lately been to drive women into clandestine prostitution, and thus to increase true syphilis, finally, we would ask, Is it the part of a wise Government to interfere with the action of adult men and women in questions in which it has comparatively little power?

THE STUDENT'S GUIDE TO DENTAL ANATOMY AND SURGERY. (*a*)

THERE is not a more useful class of text-books than that of the "Student's Guide" manuals, which have been recently projected by the well-known publishing firm of J. and A. Churchill. Considering the number of subjects which the medical student is expected to master within the short term of three or four years, he cannot commit a greater mistake than that of making his first acquaintance with either of those subjects through the medium of large and exhaustive treatises. His comprehension and his memory are confused and embarrassed by the multitude of petty details and facts with which all large works abound, and when he rises from his studies the main features and principles of the science on which he has been engaged are by no means so clearly and indelibly impressed upon his memory as they would have been had he contented himself with reading a more elementary work. For this reason we cannot commend too highly the design of these manuals, and, incidentally, of the work we are now reviewing, which is, to quote from the author's preface, "that they should be free from needless technicalities, that they should facilitate the labours of the student, and that, whilst each volume should be complete in itself, it should, at the same time, lead the reader to desire, and direct him in seeking, the fuller knowledge afforded by more extended treatises." To say that Mr. Sewill has, in the present volume, ably and faithfully carried out this design, is in itself no small commendation; but, independently of this, there are other points which entitle his work to the attention of the dental student and general practitioner; indeed, we may confidently state that it is the only attempt which has been as yet made to give a concise and consecutive account of the whole subject, including anatomy, pathology, and treatment, without entering upon doubtful and controverted matters.

In the commencement of the work we have a good description of the anatomy, histology, and development of the teeth, in which the author has incorporated the results of the most recent investigations that have been made into those subjects. Thus, with regard to the development of the teeth, and the histogenesis of the dental tissues, the descriptioms that are to be found, even in our latest text-books on physiology, are entirely based upon the investigations of Goodsir, which were published in the year 1838. Since that time the subject has been investigated by numerous physiologists, especially Marcusen,

(*a*) "The Student's Guide to Dental Anatomy and Surgery." By Henry Sewill, M.R.C.S., L.D.S.; Hon. Sec. Odontological Society; Dentist to the West London Hospital, &c.

Kölliker, and Waldeyer;' and we are glad to see that Mr. Sewill has not only drawn upon these authorities, but has also given his readers a neat summary of the still more recent and elaborate researches of Messrs. Legros and Magitot.

The physiological part of the manual is completed by a brief description of the growth of the jaws, and of dentition, and this is followed by a full account of the malformation and irregularities of the teeth. The latter subject is one of much importance, and one to which Mr. Sewill has devoted great attention, as evidenced by his well-known monograph on this particular department of dental pathology.

Of all the different subjects, however, with which dentists have to deal, there is none in which the public are so interested, or on which medical men are so frequently asked to pass an opinion, as that of the cause and nature of dental caries. There is a very general impression among the community that dentists cannot satisfactorily account for the havoc which this disease causes among the teeth of nearly every third person we meet with, and for the fact that we seldom find a sound set of teeth in any individual over 30 or 40 years of age. But this is a great mistake, as dental pathologists can give as good an explanation of the causes of the deterioration of teeth as can be given in respect of insanity or any other disease which has likewise increased within the last fifty years. The theory of the etiology and pathology of caries which our author has adopted is, to use his own words, "entirely based upon generally admitted facts; it is that which I believe can alone be arrived at by reasoning upon such facts; it is that which recently has been enunciated by the best authorities, and eventually must be, in my opinion, universally accepted." These causes are to be found in the action of acids, which occasions a gradual softening and disintegration of the dental tissues, the origin and progress of the disease being favoured by certain structural defects in the enamel and dentine, and by certain derangements of the general health. "The local and constitutional diseases which favour the onset and progress of caries are those which are accompanied by inflammation of the oral mucous membrane, and those which give rise to the formation or deposit of acid within the mouth. Among the former may be particulariy enumerated all the varieties of stomatitis; among the latter, scrofula, syphilis, phthisis, diabetes, chlorosis, and chronic alcoholism. These constitutional affections exert their baneful effect upon the teeth in great part by reason of the chronic inflammation of the gums, the vitiation (even general acidity) of the secretions of the mouth, and the dyspepsia with which they are all so commonly accompanied." A curious fact in connection with dental caries is that the teeth are not all equally liable to decay; and Mr. Sewill gives the statistics of 10,000 cases collected by Magitot, which show the great relative frequency of caries in the first molars, as well as the much greater frequency of the disease in the front teeth of the upper than in those of the lower jaw. The latter circumstance may, in the opinion of the author, "be accounted for by the fact that the lower front teeth are protected from the action of acid by the saliva with which, owing to their position, they are constantly bathed." He admits, however, that no entirely satisfactory explanation of the above facts has yet been afforded.

The chapter on "The Treatment of Caries" is particularly good, and occupies nearly forty pages of the work. Much information is given respecting the prevention of this very prevalent affection, as well as some good advice suggested as to the diet and mode of living that should be adopted by persons whose teeth show symptoms of premature decay. We all know what great progress has been recently made in hygienic medicine. This progress has certainly extended to what might be called the hygienic branch of dentistry. We are deeply indebted to the dental profession for the advancement that has been made in the pathological, therapeutical, and purely mechanical departments of their art, but it would be a great boon to the public if more systematic investigations were made into the causes and prevention of this disease. We have already referred to the valuable statistics of Magitot, and if some similar researches were made into the influence of congenital conformation, hereditary and antecedent disease in the individual or his parents, as predisposing or direct causes of caries, we cannot but think that some valuable contributions would be made to dental science. Whether the public would profit by the knowledge so obtained is quite another question. We firmly believe that the great perfection to which mechanical dentistry has been brought not only partly accounts for the comparative neglect with which the hygiene of the subject has been regarded, but has made the public themselves remarkably careless about the preservation of their teeth, and will always in some measure prevent them from adopting those prophylactic measures which science has placed in their way.

We feel, however, that we are rather digressing, and that these observations apply more to dental literature in general than to the manual we are now reviewing. Before taking our leave of it, we must state that the rest of the work contains a complete and practical account of dental periostitis, alveolar abscess, dental exostosis, diseases of the gums, the stopping and extraction of teeth, &c., &c., and all treated of in an admirably clear and concise style, which cannot fail to interest and instruct, not the student only, but the general practitioner, who, perhaps far away from any dentist, must have often felt the want of such a work as Mr. Sewill's "Manual of Dental Anatomy and Surgery."

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, MARCH 22, 1876.

LEGISLATION ON VIVISECTION.

A fussy nobleman, Lord Henniker, apparently in a great hurry for legislation on vivisection, hoped, "as he felt strongly on the subject himself," the Government would lose no time in dealing with it. He trusted "a bill would be brought in with the least possible delay." The Duke of Richmond, however, with commendable firmness, is not inclined to be hurried in the matter, nor will he let the clamour of those who have allowed their feelings to get the better of their judgment at all drive him into hasty legislation. The outrageous statements made by "the large number of persons (including Lord Henniker) who feel strongly on the subject" have been entirely refuted, and clearly shown to be for the most part gross exaggerations. Not one of the number was able to prove acts of cruelty on the part of the teachers of the medical schools of this country; and the witnesses who presented themselves before the Commissioners, ready primed with

quotations from physiological text books, and as special advocates of the anti-vivisectionists, utterly broke down. Even the representatives of sham societies got up for the total suppression of vivisection, and who had continually advertised trumped up charges of cruelty against the profession, utterly failed to make good their assertions in a single instance.

Neither Mr. Jesse nor Mr. Hutton could do more than deal in surmises and generalities, and, like drowning men, clutched at every straw carelessly flung aside by an outspoken witness. No right-thinking and dispassionate person can come to any other conclusion than that arrived at by the Commissioners, who, after carefully weighing the evidence brought before them, unanimously declared that, on the question of the unnecessary infliction of pain on any of the lower animals, "a general sentiment of humanity pervades all classes in this country. The principle is accepted generally by the highly-educated men whose lives are devoted either to scientific investigations and education, or to the mitigation or the removal of the sufferings of their fellow-creatures." Even the feelings of the students on this subject are equally pronounced and quite as humane as those of their teachers. Sir William Gull's testimony on this head is sufficiently conclusive; and he affirms "that in a medical school anything like cruelty or indifference to suffering would be scouted by the public opinion of the students, and that he had never seen anything like indifference on the subject." It is, indeed, sufficient to know that medical students of the present day are educated gentlemen, and therefore as little likely to forego or disregard the dictates of humanity as Lord Henniker and his friends.

Unscientific persons would do well to act with some modesty and restraint in the formation and expression of opinions on a matter like this, since they are less keenly alive than perhaps they ought to be to the great importance of physiological research; at all events, they would do well to keep silence, and turn with some deference towards a profession to which they must at some period or other of their lives be under some obligations. Sir Thomas Watson could see nothing to condemn in vivisection as practised in this country; on the contrary, he stated as his deliberate opinion, that when made for "some definite object, some plain question to be settled, some important doubt or uncertainty to remove, some hypothesis containing a promise of service to humanity to be confirmed or confuted, at least some reasonable hope of and prospect of resulting benefit," that then the means perfectly justified the end.

The same line of argument was employed by Sir James Paget, who said, "in his opinion, that experiments on animals susceptible of pain ought not to be prohibited, even if it were possible to do so. All medical science," says Sir James, "being in a state of progress, is continually coming in sight of problems which can only be solved by experiments either upon man or upon some lower animal; so that if a patient suffering from injury or disease is brought to a physician or surgeon, he must either adopt some course of cure which has become known to him from the former experience by himself or others on animals, or else he must adopt upon conjecture the remedy which he thinks most likely to be useful; that is to say, he must submit the present patient to an experiment instead of proceeding to his treatment with the assuance which might have been given by past experience." We save ourselves, as Mr. Simon expresses it, "a great deal of needless experimentation on man by some experimentation on the lower animals." "This cogent argument," observe the Commissioners in their report, "is evidently susceptible of indefinite illustration from memorable cases which have from time to time occurred in history;" and "it would require a voluminous treatise to exhibit in a consecutive statement the benefits that medicine and surgery have received from these discoveries."

Nevertheless, we do not wish to deny Lord Henniker and those who are with him the gratification of legislative interference to prevent even the semblance of abuse. We have already expressed our opinion on this point, believing that some kind of State interference is called for in the interests, not only of humanity, but also of science, for, as the Rev. Dr. Vaughan, with the characteristic of a master mind, puts it, "those to whom we turn in our keenest distresses, and to whom we never turn in vain, have a right to our most scrupulous, most respectful regard, when the topic is one upon which *they know* where *we guess*."

REPRESENTATION OF SURGERY IN THE GENERAL MEDICAL COUNCIL.

The deaths of Dr. Warburton Begbie and Dr. Parkes have placed at the disposal of the Crown two of the seats on the General Medical Council, and we accept the opportunity to represent once again the altogether inadequate and unjust representation of surgery in the Council. In the year 1873, when Sir Robert Christison and Drs. Stokes, Parkes, and Quain went out of office, we called attention to the matter, but as all these representatives were re-elected except one, the opportunity did not arise for the Government to show its policy. It is different now, and we trust that the mistake will not be committed of appointing a physician in the room of Dr. Begbie, and thus still further weakening the influence of surgery in our Medical Parliament. The profession will be surprised on being reminded that of the twenty-four members of the Council only three are pure surgeons, viz., Mr. Quain, of the London College of Surgeons; Mr. Macnamara, of Dublin; and Mr. Fleming, of Glasgow. The remaining twenty-one, with three exceptions, are not only physicians in practice, but most of them are bound in the most intimate relations with universities or colleges of physicians, many of them holding professorships or other offices in purely medical licensing bodies. The three exceptions to this rule are Professor Humphry, of Cambridge, and Mr. Turner, of the Scotch Universities —who are rather anatomists than surgeons—and Mr. Bradford, of the London Apothecaries' Hall, who is an ex-military medical officer, and not, we believe, in practice at all.

Out of seventeen licensing bodies who send delegates to the Council, eleven are almost purely medical, and three others—the Apothecaries' Companies and the Glasgow Faculty—are neuter. The proportion of four physicians to one surgeon is accurately maintained in a scrutiny of the

representatives themselves, twelve of whom are practising physicians, while only three are pure surgeons, and two others who may be considered as neutral.

These facts leave no doubt whatever on our minds that there is a serious peril that surgical interests and the status of the surgical profession must take a subordinate position in the estimation of the Council, as long as so large a preponderance of one side exists. It was originally in some measure to correct this anomaly that the five Crown nominees were introduced into the body, and the object of our argument is to show that it is the bounden duty of the Privy Council to restore, as far as possible, the balance of power by the appointment of a Crown representative, which they are on the eve of making.

It is unnecessary for us to argue that surgery is deserving of a larger representation than it receives. The three surgical corporations we believe we may say confer a greater number of qualifications to practise than all the medical licensing bodies put together, and the surgical diploma is always recognised as the first and most important qualification, towards which the medical licence occupies a subsidiary though necessary relation.

The Council was originally, and is still, so constituted that, as regards its representative element, physic has always been in an overwhelming majority over surgery, and it appears obvious to any one who examines the list of licensing bodies who appoint, that for this reason alone the surgical corporations would stand a poor chance should any question arise in which their interests clash with the universities and the bodies who confer purely medical diplomas. Such a contingency is by no means visionary. At any moment—such question may arise as whether one or two courses of lectures on anatomy shall be required of the student, or whether two or four examiners shall test the candidate in surgery, and it does not need to be a prophet to foresee the verdict at which the Medical Council as now constituted, would arrive.

Her Majesty's advisers have it in their power to equalise to a certain extent this preponderance of the speciality of medicine over that of surgery, and we trust that they will recollect the interests that are at stake and protect the rights of the surgical corporations, who, it appears to us, would do wisely to take steps to represent the facts to the Privy Council, and claim for the profession which they represent something like an equal share in the constitution of our professional Parliament.

MILITIA SURGEONS.

The same miserable spirit of cheese-paring economy and hostility which has been evinced towards the medical officers of the army is being also exhibited towards the medical officers of the militia, and, as a consequence, we may expect to find, in a short time, the auxiliary forces without any surgeons at all. As it is, indeed, there are nine Irish militia regiments now without a surgeon! the medical duties of those regiments being performed either by a civil practitioner or, in case of there being an assistant-surgeon still in the regiment, by that officer. The militia surgeon has been deprived of the recruiting, and, with it, of a certain income, and this without any fault on his part. The recruiting duty is now done by the army surgeon free of expense, and the country is therefore saving money at the expense of the militia surgeon, who, in order to retain his militia appointment, often relinquished private practice or other appointments. Even the miserable pittance of twopence per week paid for attendance on the permanent staff will be taken away from the militia surgeon as soon as the depôt centres are completed, and he will be called upon merely for the annual training—possibly in England or Scotland, or other place remote from his home—when he will have to give up his private practice and procure, if allowed to do so, a paid substitute for his public appointment! Assistant-surgeons naturally look for promotion, and formerly, as a rule, obtained the surgeoncy of their regiment, whenever it became vacant, and, of course, the emoluments of the office. Now appointment to surgeoncy has been suspended, and the assistant, when such exists, is required to do the whole duties of the regiment on his assistant's pay! without the inducements of promotion in rank or emoluments! What a boast for an enlightened War Minister of Great Britain in this century to say he can effect a saving of £1,000 per medical man per ten years in the army, and getting double the work out of him as formerly, and that he can get his auxiliary forces medically looked after for next to nothing! A new warrant has been promised to the militia surgeons by the present Secretary of State for War over and over again, but this warrant is now as great a myth as it was a twelvemonth ago. The present militia surgeons are kept dangling on, not knowing what further blow they may sustain. Surely it is time this gross injustice to a profession on which depends the safety and well-being of our army should cease, and it is time our Government learned from neighbouring enlightened States how to deal with scientific men and with a learned profession.

Public corporations, Government servants, public officials have been compensated whenever their services have been dispensed with by the country—viz., the Irish Church, proctors, army agents, law officers of various kinds, and recently militia adjutants, have been liberally induced to retire; the militia surgeons are fully entitled in all equity and justice, to have their grievances redressed, and to receive fair compensation for loss of emoluments.

We fully expect at the next army medical examination a similar fiasco to that at the last; the intending candidates, at least in this country, see through the ten years' dodge and the £1,000 inducement; the English Minister entirely ignored that the Irishman does not look forward to buying and selling the medical profession as a piece of broadcloth at the end of ten years, but that he looks to an honourable career in a non-mercantile profession. The feeling in the Dublin School, so far as we have been able to learn it, is to hold aloof from the army so long as its medical department is managed as it now is.

The position and pay of the militia surgeon should be restored, and the claims of the assistant-surgeons respected.

Notes on Current Topics.

Mr. Gibson's Bill.

THE following is the text of the Bill introduced by Mr. Edward Gibson, M.P. for Dublin University, to throw open Irish infirmary surgeoncies to all duly qualified surgeons, and to put on the Register all bachelors in surgery and State medicine diplomates of the University. The Bill is "backed" by Dr. Cameron, Mr. Mulholland, and Dr. Ward :—

A BILL TO ENABLE LEGALLY QUALIFIED MEDICAL PRACTITIONERS TO HOLD CERTAIN PUBLIC MEDICAL APPOINTMENTS, AND TO AMEND THE MEDICAL ACT.

WHEREAS under the provisions of the statute of the thirty-sixth year of the reign of King George the Third, chapter nine, of the Parliament of Ireland, no person is capable of being elected surgeon to a county infirmary or hospital in Ireland who shall not previously have obtained letters testimonial of his qualification under the seal of the Royal College of Surgeons in Ireland :

And whereas it is desirable that all legally qualified medical practitioners, with qualifications in medicine and surgery registered under "The Medical Act," should be capable of being elected to all public medical or surgical appointments, anything in the said Act or any other Acts to the contrary notwithstanding.

And whereas it is desirable that persons who have obtained the degree of bachelor in surgery or the diploma in state medicine of any university in Great Britain and Ireland, legally authorised to confer such degree or diploma, should be empowered to register these qualifications under "The Medical Act :"

And whereas the said objects cannot be effected without the authority of Parliament :

Be it therefore enacted by the Queen's most Excellent Majesty, by and with the advice and consent of the Lords Spiritual and Temporal, and Commons, in this present Parliament assembled, and by the authority of the same, as follows :

1. This Act may be cited for all purposes as "An Act to enable legally qualified Medical Practitioners to hold certain public Medical Appointments, and to amend the Medical Act."

2. Notwithstanding anything contained in the said Act of the thirty-sixth year of the reign of King George the Third, chapter nine (Ireland), or any other Act of Parliament, all legally qualified medical practitioners with qualifications in medicine and surgery registered under "The Medical Act" shall be capable of being elected to all public medical or surgical appointments, and when so elected shall for all purposes be deemed to be duly appointed, and be entitled to all the emoluments and advantages, and liable to discharge all the duties of the said offices.

3. All persons who have obtained from any university of the United Kingdom legally authorised to confer the same the degree of bachelor in surgery or a diploma in state medicine shall be permitted and are hereby empowered to register the said degree and diploma or either of them as qualifications under "The Medical Act" anything in the said Act to the contrary notwithstanding.

There are two points which strike us on perusal of this measure.

In the first place, Mr. Gibson justly proposes to abolish an exclusive privilege of the Irish College of Surgeons, and it would be fair that any similar monopoly in England should also be removed. There are in England many public institutions for the surgeoncies of which none can compete but members of the London Colleges of Surgeons or Physicians, and, though many of these institutions may not be within the reach of Mr. Gibson's Bill —not being regulated by any Act of Parliament—yet we believe that this exclusion is practised in hospitals which are incorporated either by Act of Parliament or by Letters of Incorporation, and any of them which Mr. Gibson can lay hand on ought certainly to be subjected to the same law as the Irish county infirmaries.

In the second place, Mr. Gibson's Bill involves in its last clause the establishment of a very serious precedent. By it a person holding a diploma in State medicine will be entitled to demand that it shall be registered under the 15th section of the Medical Act, and, it being so registered, the holder becomes at once entitled under the 34th clause to enjoy all the privileges of a duly qualified medical practitioner. Now the diploma in State medicine is not a medical, but rather a hygienic qualification, and it requires no curriculum or examination such as should entitle a person to practise. It might indeed be obtained by an engineer or a doctor of laws for anything which the subjects of examination include, and it therefore ought not to confer the privileges of duly qualified practice. At present it is restricted by Trinity College to M.D.'s of a University, but it would be open to the Board to remove that restriction at any time, and thus throw open medical practice to persons not suitably qualified. The clause of the Bill, as it stands, ought not therefore to be accepted by the licensing bodies or the Medical Council ; but as we imagine this view of the matter has escaped Mr. Gibson's notice, there need not be any difficulty in recognising the State medicine as an additional qualification registrable *after* a proper licence to practise has been obtained under section 3 of the Act, and with a special proviso added to the clause to the effect that the diploma shall not confer any right to practise.

Noxious Trades.

ON Friday last a deputation waited upon the President of the Local Government Board to ask for a Royal Commission or some more restrictive measures under the Alkali Act. It is well known that since the passing of this Act, together with the Smoke Nuisances and Noxious Trades Acts, many of those evils which so seriously affected the public health have passed away or been considerably mitigated, and it seems to us that the Royal Commission asked for is superfluous. Parochial authorities have only to apply the law whenever the existence of a nuisance prejudicial to health can be proved, and the law is quite strong enough to stop it. The President of the Local Government Board appears to have entertained the same views, as he gave the deputation to understand that the public had the means of protection if they would only take the trouble to use them.

Ministerial Infallibility.

NO great confidence can be placed in the tactics of a minister who displays *ab initio* a grotesque ignorance of the circumstances for which he is called upon to legislate; but such an unacquaintance with his subject is worse than imprudent when it is accompanied by an apparent determination not to learn, lest the information acquired should interfere with the solidity of the structure raised upon the foundation of the minister's imagination. We noted last week the impertinence of Mr. Gathorne Hardy's reply to Mr. Dunbar's very fair representation of the inapplicability

of the minister's short service scheme to Irish candidates. If Mr. Hardy had been only flippant, no one would be hurt by his mode of speech but himself. He was more—he was ignorant, and showed himself so when he said, "a great number of the candidates for army surgeoncies were Irish, and he could not believe that the terms which suited the English officers would not be acceptable to them. *It was equally incredible that the goodwill of a surgeon's practice, or of any other business, was not to be purchased in Irsland.*" "Incredible" as the fact may be to a minister who has not extended his inquiries beyond Cockneydom, it is absolutely true. The goodwill of a surgeon's practice has never to our knowledge been purchased in Ireland, and could not be so, because Irish practice is essentially a ready-money business, and there never remain at the death of an Irish doctor any book debts which can be transferred as they are in England. The point is not a very important one, because an Irish army surgeon receiving his £1,000 will not be restricted to Ireland for a professional investment; but it is useful and instructive as an evidence of the confusion of ideas which exists in the ministerial Babel in reference to the medical affairs of Ireland.

Dr. Livingstone's Family.

The *Scotsman* announces that Mr. Thomas Steele Livingstone, the elder son of the famous African traveller, died on Wednesday last, at Alexandria, whither he went about three years ago for the benefit of his health. Dr. Livingstone's surviving son is resident, as a medical practitioner, at Trinidad.

The Vaccination Acts.

In the House of Commons on Thursday last, Mr. Sclater-Booth, President of the Local Government Board, stated that he had received several complaints from persons who had been convicted under the Vaccination Acts. He would lay upon the table a copy of a letter which he had caused to be written to some boards of guardians, in which the opinion of the Local Government Board was stated as to the legal aspect of the question and as to the power left to the discretion of the guardians.

The Action of the Coca Leaf.

It was reported that Mr. Weston, who has recently obtained such celebrity in London by reason of his unparalleled walking feats, continually chewed pieces of the South American coca leaves as a nerve stimulant and preventive of exhaustion. It appears that Mr. Weston chewed the leaves only during the time that he made the ten miles from the 65th to the 75th mile of the first walk, but that he did not find them produce the desired effect. Instead of keeping him awake or stimulating his efforts, they, on the contrary, acted as an opiate with him. Mr. Weston says that after an experience of upwards of eight years in public life, during which time he has walked over 14,000 miles, experience has taught him that Nature should not be outraged by the use of artificial stimulants in any protracted trial.

Testimonial to Dr. Maurice Corr.

Thirty years ago, when the position and emoluments of dispensary medical officers in Ireland were miserable, Dr. Corr devoted himself, at the request of the Council of the Royal College of Surgeons, to the task of securing from Parliament such legal enactments as would raise their status. As the delegate of the College, and subsequently as Assistant Poor-law Commissioner, he successfully pressed on Parliamentary Committees and successive Governments the need of a complete reorganisation of the medical charities, and, in fact, originated the reform which has raised so highly the position of dispensary physicians and quadrupled their incomes. His devotion to this work withdrew him from remunerative professional occupation; the position thus lost he was never able to regain, and he is now, at the close of a long life, in most straightened circumstances. His claims to the sympathy and assistance of his brethren was felt by the Fellows of the Royal College of Surgeons to be so strong, that at the annual meeting in May, 1875, it was unanimously resolved—"That it is the opinion of this College that the faithful and very important services rendered by Dr. Corr to the College and to its Fellows and Licentiates holding Poor-law medical appointments throughout Ireland are hereby recommended to the Council for favourable consideration, with the view to remunerate him for those services, and for the serious sacrifices incurred by him in his endeavours to benefit his professional brethren." To this resolution, however, the Council found they could not give effect, in consequence of the legal obligations of their Charter, and a committee has therefore been formed for the purpose of collecting from the members of the profession, especially those connected with the Poor-law Service, a sum to supplement Dr. Corr's income, at present most precarious, and insufficient for giving him and his family the necessaries of life.

The following gentlemen have kindly agreed to act on the committee and receive subscriptions:—Dr. C. Benson, 42 Fitzwilliam Square West, Dr. Chapman, Hon. Sec. Irish Med. Assoc., 60 Pembroke Road, W. Colles, Esq., Regius Prof. T.C.D., 21 Stephen's Green, Dr. Darby, Bray, Dr. Hayden, Vice Pres. Coll. of Phys., 30 Harcourt Street, Dr. James Little, 24 Lower Baggot Street, Dr. O'Leary, M.P., 38 York Street, J. H. Wharton, Esq., 28 Upper Merrion Street, W. I. Wheeler, Esq., 56 Pembroke Road, Dr. Mapother, 18 Merrion Square North, Hon. Sec. and Treasurer.

Food in Military Prisons.

In the Annual Report for the Military Prisons, just published, Dr. Gore, the surgeon of the Dublin Military Prison, raises the question as to the sufficiency or otherwise of the food supplied to the inmates of these establishments. The loss of weight was sometimes considerable, and as most of the men were under their 25th year, and many under 20, "there should be an excess of food, and not a deficiency, as the system requires not only sufficient for the normal interchange between the blood and tissues, but an excess, to keep up the process of growth and consolidate new tissues; when the amount is not sufficient in quantity, or unsuitable in quality, the latter invariably degenerate as frequently as not with morbid growths, the

germs of future incurable disease." Particular objection is taken to the Indian meal, and it is urged that a third meat dinner should be given to every prisoner during the week. The diet proposed would yield a "nutritive value" commensurate to the wants of the system and the hard labour of shot drill, and allow a margin for punishment entailing deprivation of a portion of the ration. Indian meal has long since been banished from the dietary of civil penitentiaries, and according to Professor Cameron, although the composition of "Indian meal or maize indicates a very high nutritive value, it is not well-flavoured, and is better adapted for the food of the lower animals than man." The fact has often been commented upon by military surgeons of experience, that men who have undergone long terms of imprisonment at Millbank and other large civil gaols very frequently return to their regiments broken in health. No problem is surrounded with greater difficulties than that of the prevention of crime, and the question raised in these reports is not the least difficult to answer.

Professorship of Hygiene at Netley.

THE lamented death of Professor Parkes leaves this very lucrative appointment vacant. The emoluments are considerable, very little short of £1,000 per annum—£858 in direct pay. We presume the Government will adopt the usual course of advertising for candidates for the office, if the new short service scheme does not do away with the necessity for retaining the Army Medical School. However eminent may be the claims of any individual, we think it only due to the public and the profession that the Professorship should be thrown open to any one who may be in a position to claim it on the ground of peculiar fitness.

Vivisection Witnesses.

THE *Globe* has written some clever articles upon the examination of witnesses before the Royal Commission on Vivisection, from which it appears that the Commissioners were to be pitied, for no mercy was shown them. After vain protests, they discovered that the best plan was to let the witnesses talk until they had exhausted themselves and were absolutely compelled to stop. One gentleman, calling himself the representative of a society, spoke at inordinate length on three different occasions, reading a vast number of extracts from various authors, including the story of *Newton and the Pebbles on the Sea-shore.* This gentleman further insisted that Professor Huxley had, in his little educational work on Physiology, directly encouraged children to practise vivisection on cats and dogs, and the more Professor Huxley attempted to show that such was a complete misunderstanding, the more wild and reckless were the statements made against him. The Secretary of the Society for the Prevention of Cruelty to Animals gave evidence to the effect that he was present at a lecture delivered by Professor Ferrier before the London Institution, and that he was much shocked at the lecturer's levity. He informed the Commission that he heard Professor Ferrier say that "the animals 'appeared' to be in intense suffering, and then joke about the stupidity of the animal, especially if the animal happened to be a monkey, giving humorous descriptions of its behaviour; so much so, that at times there was general laughter in the lecture place." Three gentlemen were with the Secretary, and "one of them left the room in disgust." "The skill of the lecturer," he declared, "was used to cover the grim character of the experiment by his humour."

Such evidence was to the Commissioners doubtless tedious in the extreme, but they endured it patiently. We do not hesitate to affirm that no English audience, much less an educated audience, would listen to or participate in jokes based upon the sufferings of dumb animals.

Treatment of Dysentery with Salicylic Acid.

ACCORDING to the New York *Medical Journal*, cases of acute dysentery have been treated satisfactorily in that city by means of doses of thirty grains of salicylic acid administered three times a day. The only objection to the remedy appears to be a slight irritation of the stomach, but this is not sufficient to cause emesis.

Improvements in Dublin Hospitals.

THE new wing of Mercer's Hospital is making rapid progress towards completion, and will be a great advantage to the hospital when completed. The committee of the Adelaide have decided to build extensive additions to the hospital, which will provide the institution with a fever hospital, two convalescent rooms, a mortuary, sleeping rooms for the resident pupils and for the registrar, rooms suitable for lady nurses and additional rooms for training nurses, two small wards in connection with the operating theatre, and a covered communication between the operating theatre and the hospital, or a new operating room in a more convenient situation, and a few other necessary additions, such as single pay wards and eye wards. The rebuilding of Jervis Street Hospital is still in abeyance, though we believe the funds are in hand for the purpose.

Ringworm seen Six Hours after Birth.

WE publish this week in our "Clinical Records" the report of a case under the care of Mr. Roche Lynch, in which ringworm made its appearance upon the face of a child within six hours after its birth. About the character of the disease no doubt existed, and so close to the time of birth was it detected, that, absurd as it may appear, there was strong evidence in favour of congenital ringworm. The problem was, however, soon solved; for Mr. Lynch discovered the cause in the clothes of the nurse, who, four days previously, had been nursing a child affected with the disease. The case is interesting, inasmuch as it shows that spores of the fungus may remain upon articles of clothing without drying up, or at any rate without losing their vitality for at least four days; and secondly, that when planted in the skin of an infant, they can multiply within a period of six hours to such an extent as to render the disease distinguishable to the naked eye.

Excerpta Medica Ridicula.

IN an English prison recently a patient died of small-

pox, on whom an inquest was held. We are told that in consequence of the outbreak the coroner took every precaution to prevent the spread of the disease, and the jury, instead of viewing the body in the ordinary way, *looked down upon it from an upstairs window.* The jury returned a verdict that the deceased died from natural causes.

A New Preparation of Santonine.

ALBUMINATED sodium santonate has recently been much recommended as an anthelmintic. It is prepared by gently heating in a porcelain dish a mixture of four parts of sodium bicarbonate, one part of santonine, and two parts of dried, soluble egg or blood albumen, with a small quantity of water, until a solution is effected; this is evaporated to dryness and subsequently re-dissolved in a sufficient quantity of warm water; the filtered solution is evaporated at a gentle heat to dryness. The remaining albuminated sodium santonate forms colourless, shining scales, readily soluble in water, rendering an alkaline solution which, upon addition of acids, separates santonine with the evolution of carbonic acid from an excess of sodium carbonate.

A Novel Signboard.

IN one of our northern (Ulster) towns lived a medical gentleman, with his brother, a clergyman, in joint occupation of the same house. The doctor's surgery was on the ground floor, and his reverence had his study on the first flat. One morning the doctor was at his street-door, when Jemmy, an old house-painter, well known in the place, came up with "A fine morning, doctor." "Very, indeed, Jemmy. What are you doing?" "The ne'er a hait, sir. Can you gie me a jab?" "Oh, I've nothing in your line to do," said the doctor. "Yes, but you have," said the painter. "You'll be wanting a sign for the front of the house." "Then," said the doctor, "what would you put on it, Jemmy?" "Just this, doctor—

'Souls and bodies repaired with skill,
By the Reverend Richard and Doctor Dill.'"

A New Infirmary for Earlswood Asylum.

AT the anniversary festival of the supporters of this national institution, on Wednesday last, an earnest appeal was made by the Chairman, the Earl of Shaftesbury, for a new detached infirmary, which the medical staff deemed most essential. The building now contains more than 600 inmates from all parts of the kingdom, and although at each half-yearly election there are upwards of 220 applicants, the board cannot usually elect more than 30 or 35; consequently the want of a detached infirmary is more urgently felt. The estimated cost would be about £5000. The Chairman remarked that the medical and general superintendence of the Asylum were highly spoken of by the Commissioners in Lunacy, and he trusted the public would come forward in that spirit of liberality they had done on former occasions, and enable them to build what was so urgent a necessity. This appeal was not without its effects, no less a sum than £2,172 being at once subscribed in the room.

International Congress of Medical Sciences.

ACCORDING to the resolution passed at Brussels by the last periodical Congress of Medical Sciences, the fifth meeting will take place at Geneva in 1877. The Congress, which will be exclusively scientific, will last a week, and will commence on Sunday, the 9th September, 1877. A committee has been organised in concert with the scientific section of the National Institute (Geneva), who will receive all communications relative either to the Congress or to questions which will be made the subjects of its deliberations. Such communications should be sent in before the 1st June, 1876, at which time the committee will arrange the rules and the programme.

Cancerous Ulceration of the Tongue following Lingual Psoriasis.

AT the last meeting of the Société de Chirurgie at Paris, M. Trélat read the case of a man fifty years of age, formerly a great smoker, who had given up smoking for eight years, in consequence of the appearance of patches of psoriasis upon the tongue. He at that time underwent the treatment for syphilis, but without effect. About twenty months ago a cancerous ulceration took the place of the patches of psoriasis, and ablation of the growth was advised. The patient, who refused to have any operation performed, died last year.

It has been said that if a person, over forty-five years of age, has an irritable cutaneous spot of any description, and continue to further irritate it by picking, epithelioma will develope itself. This may be an exaggeration; but nevertheless, epithelioma generally makes its appearance in parts which are continually exposed to irritation. In the case above reported a cancerous deposit would not lie dormant over a period of eight years, it is therefore probable that the inflamed condition of the mucous membrane at the seat of the psoriasis, continually irritated by food and condiments, determined the locality of the cancerous outbreak.

WE understand that it is Mr. Haviland's intention to offer himself for re-election as Medical Officer of Health for the combined sanitary districts of Northampton.

DR. DICKINSON will lecture on the Pathology and Relations of Albuminuria, at the Royal College of Physicians of London, on March 22nd, 24th, and 29th, at five o'clock.

THE Municipal Council of the town of Lyons has just voted the sum of 5,000 francs for the creation of a night medical service organised similarly to that recently created at Paris.

A MAN was summoned in London for driving and offering for sale a horse affected with glanders. It was not proved that the defendant was aware of the nature of the disease, and he was therefore fined only 8s., with £3 2s. costs.

SMALL-POX is still very prevalent amongst the natives in Bombay; several Europeans have also fallen victims

to it. Numbers of people are being revaccinated. The disease is also present at Allahabad.

THE Irish Pharmaceutical Society has held its first examination, at which nine out of ten candidates were passed as pharmaceutical chemists. The first Preliminary examination is to be held the first week in April.

IN answer to a question by Mr. W. Williams, Mr. Sclater-Booth has intimated that he is not inclined to meddle with the Sale of Food and Drugs Act again this session. The desire of the former gentleman seemed to be to make the appointment of analysts compulsory.

THE Exhibition of Scientific Apparatus will be open in London, in the Exhibition Buildings, South Kensington, from April 1 to September 30. Nearly every European country will contribute, and the collection cannot fail to prove highly interesting.

AT Southampton an inquest was held on the body of a lady, the wife of a member of the medical profession. She had committed suicide by taking half-an-ounce of prussic acid. Notwithstanding the excessive dose, death did not take place for an hour and twenty minutes.

[MR. JAMES ALLAN PHILIP, M.A., M.B., &c., Senior Assistant Medical Officer of the Gloucester Asylum, has been elected Resident Medical Superintendent of the Lincoln Lunatic Hospital in the room of Mr. F. D. Walsh, who, after discharging the duties of the office for nearly thirty years, resigned a few weeks ago.

AT King's College Dr. Johnson has resigned the Chair of Medicine, and a Chair of Clinical Medicine has been established, to which he has been appointed, retaining at the same time his physicianship at the hospital. Dr. Beale has been appointed Professor of Medicine, and an additional assistant-surgeon is also to be appointed at the hospital.

DIFFICULTIES having arisen in the carrying out of the provisions of the Adulteration Act in Ireland, chiefly regarding the purchase of samples for analysis, Sir Michael Beach has put himself in communication with the President of the Local Government Board on the subject, and some legislation will probably be necessary to deal with the difficulty.

THE *Canada Medical Record* says of Montreal, "Few cities of the old world, with their crowding and their filth, show such a ratio as we do, and we believe that on this American continent we have the disgraceful honour of having the largest death-rate. The total mortality for the year 1875 was 6,311. 784 were from small-pox. This would make the startling death-rate of 50 per 1000, or a little over."

THE *Moniteur*, remarking that about fifty medical men have been elected Deputies, indulges in some raillery on the odd affinity between politics and therapeutics, and suggests that the law might fordid them to tout for votes as well as for legacies. It observes that these doctors are not always eminent in their profession, and mentions one famous for treating whooping-cough and measles, who charges nothing, and owes his election to his consequent popularity. This reward, it thinks, rather takes the gilt off his beneficence.

THE *Revue de Thérapeutique Médico-Chir.*, referring to the secretion of milk, mentions the power possessed by camphor and castor-oil in preventing the secretion, and advises their employment in the form of the following liniment:—

Ess. menth. pip., 6 gr.
Ol. ricini, 110 gr.
Ess. bergamot., 6 gr.
Camphor, 25 decigr.

A BAZAAR for the benefit of the building fund of the Stewart Institution for Imbecile Children is fixed to take place on Thursday, 20th April, 1876, in the Glass Building of the Exhibition Palace. Between £3,000 and £4,000 are still required to complete the new buildings at Palmerston, county Dublin.

The bazaar is under the patronage of a number of ladies of the highest position, her Grace the Duchess of Abercorn and Lady Georgina Hamilton being at the head.

A number of ladies well known in Dublin will preside over tables, and the committee propose to give the privilege of life votes to ladies contributing five guineas worth of work and to those who will *sell* twenty guineas worth of work.

Correspondence.

INFANTILE DEFORMITY.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Perhaps the following cases are of interest enough to obtain a place in your journal.

I give you *verbatim* the entry in the prescription-book of the dispensary of the first case, and also literally the observation entry in the relief-register of the second.

On the 29th of May, 1862, I visited, as a dispensary patient, C. C., aged 18. an unmarried girl, ill in labour. I could not satisfy myself as to what the presentation was, but the labour advanced favourably, and in two hours the child was born alive. It was strangely deformed. The top of the cranium was entirely wanting, and the brain covered by the membranes alone, was exposed to view just as if the bones had been removed in the ordinary way for making a post-mortem examination or dissection of the brain; the half of the frontal, the half of the occipital, and the whole of the parietal bones seemed wanting. The face was perfect, and was handsome. There was some imperfection of the genitals. There seemed at first view to be a penis without testicles; the site of the testicles, however, much resembled imperfect labiæ to an imperforate vagina. I put my fingers on each side and stretched the skin to see if there were an opening, and the sulcus seemed as if it were only closed by a thin membrane. The child lived seven hours. I wished to get it for a more particular examination, but could not. I think on examination the child would have been found a female. The mother made a perfect recovery. She was not blamed for tight lacing to conceal her pregnancy.

On the 8th of February, 1876, I visited M. G., aged 20, an unmarried girl, who had that morning given birth to a male child. The child had a large ventral hernia in the median line just above the umbilicus. It was as large as a large orange, and covered only by the transparent peritoneum; it

was attached to the margin of the ventral opening through which it passed, and it could not have been returned even if it had not been so attached, the abdomen being evidently too small to contain it. More than half of the hernia was composed of liver. The child lived two days. It was said that the mother laced tight to conceal her pregnancy.

D. JAMISON, M.D.

Newtownards, March 4, 1876.

OUR COLLEGES AND UNIVERSITIES.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—I will, with your kind permission, make a few remarks on the above, as I am of opinion that this important question has not been subjected to the public criticism which it deserves.

You appear to convey in your journal of the 8th inst. that as long as the Irish College of Surgeons retains its present bye-laws with reference to the preliminary examination, so long will it keep down its educational standard. I would ask, have ever "licentiates" of the Irish College been found more wanting in education, either general or professional, than the "licentiates" on this side the Channel or north of the Tweed? I have always held that the "Irish licentiates" will bear favourable comparison, whether it be with graduates or licentiates of their own or other countries. The fact of a student being unable to pass the preliminary examination at the time when circumstances often compel him to commence attending dissections and hospital practice is no guarantee of lack of knowledge on his part. Many students who have received a good general education and neglected reading up when deciding upon the profession or business of their choice, have found themselves unequal to the preliminary when the time for undergoing such examination arrived. Would a few weeks "grinding" enable such men to enter upon professional studies with more competency after than before the "cram?" I have always condemned "grinding" for examinations, whether in general or professional subjects, as I cannot appreciate its tendency towards *culture* in the proper acceptation of the term. The Q.U.I. recognising lectures attended previous to passing the preliminary does not detract anything from the merits of its graduates. Both the Irish College of Surgeons and the Q.U.I. require the preliminary to be undergone successfully before admission to undergo the first professional can be granted. What more is necessary to warrant sufficient general education on the part of a candidate for entering the profession I cannot conceive.

You never come down upon T.C.D. in your able articles, and I must state that I know of no university or college whose mode of educating students for the profession is more worthy of condemnation. Far be it from me to write anything untruthfully disparaging concerning the time-revered University of Dublin. Let me glance at the method of education carried on at this much respected University: A gentleman matriculates with knowledge just sufficient to pass, after in many cases a few "tips" from the "grinder," at the expiration of four years this gentleman returns from the University a B.A., M.B., M.Ch., and is looked upon as thoroughly educated both in arts, medicine, and surgery; but when he comes to discuss an ordinary mathematical question, to render literally a Greek or Latin author, or to pronounce his diagnosis and treatment upon an obscure medical or surgical case, he is alike inferior in attainments to what gentlemen in possession of such documents should be. However, such is the case, and a reference to the "T.C. prospectus" will show that the arts and medical degrees are practically obtainable at the same commencement of study and at the end of four years. The aim of the majority of medical students is to obtain diplomas, *not* information; on these grounds I consider that the method of Dublin University education should be condemned. I do not mean to write that Dublin graduates are all inferior men, quite the opposite, believing as I do that T.C.D. is THE place in Ireland for education, that is, for gentlemen who really love the profession, and as a consequence, it turns out some first-class men. That a T.C. student can become a graduate of his University, and at the same time be uneducated and below the average licentiate, is beyond question. The "programme" of the T.C. examinations is the greatest ornament which T.C. can at present boast of; but we must not judge a graduate entirely from the programme of the subjects in which he may have been examined previous to the conference of his degree. Let us look at the time which he occupied in becoming acquainted with such subjects, and if competent, ascertain his attainments personally. We will at once see that thirty-six months is not the time to become thoroughly educated both in arts, medicine, and surgery. I consider that requiring a student to be a graduate in arts before admitting him to the medical profession, necessitates the laying of too laborious a foundation, and that entering it without passing a good examination in general education is building too bold a superstructure. The conference of degrees after a thoroughly searching examination, such as at the Q.U.I. often makes men scholars against their inclination. I am therefore an advocate of the extensive examination, and not of the extensive curriculum system, as by the former a man must have acquired, and by the latter he may have acquired if he will. If the Irish College of Surgeons alter the bye-laws as suggested heretofore, I will with displeasure be obliged to witness the deterioration in number, and not change of educational superiority of its licentiates. Apologising for this already too long communication,

I am, Sir, yours faithfully,

3 St. Andrew Street, Blackburn. SURGEON.

[We publish this letter in order to give free expression to all views on the subject, premising that we do not agree with any part of it.—ED. M. P. & C.]

ELECTION OF THE EXAMINER IN ANATOMY AND PHYSIOLOGY AT THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—I was much pleased with your terse and valuable article of last week referring to the intended appointment of an Examiner in Anatomy and Physiology at the Royal College of Surgeons of England.

I believe it to be a fact that Mr. Hulke was appointed to the vacant post at the sitting of the Council on Thursday last. I have been unable to ascertain, though I have made sufficient inquiry, that Mr. Hulke was ever virtually a teacher of anatomy at any medical school that is recognised and advertised as such in any curriculum of medical education.

I am well aware that it is difficult for the College of Surgeons to obtain examiners who have taught both anatomy and physiology; indeed, so few men are to be found with this double qualification that in all probability the Council will have to select physiologists as such, and not require them to be examiners in anatomy as well. I should be satisfied with Mr, Hulke's appointment on the score of physiology alone if he had at all distinguished himself, or if he had been recognised as a physiological teacher. When I refer to the "Medical Directory" I find no reference to his physiological capabilities. On making further inquiry, however, I ascertain that he did assist a physiological lecturer at the Middlesex Hospital some years ago in his course, choosing those subjects for which he had a fancy. This certainly does not satisfy me as a Fellow of the College of Mr. Hulke's fitness for the appointment, because, when the Board of Examiners was instituted, apart from the Court of Examiners, it was to insure that the former, who were to examine in anatomy and physiology, should be men who were or had been teachers in those subjects.

I agree also with you in your stricture on the deficiency of the committee of selection in sending up only one candidate to the Council for election, for by this act they converted themselves into delegates, and were virtually electors, instead of being a committee of selection sending up several names from which the Council could exercise its choice.

I am, Sir,

A FELLOW OF THE COLLEGE.

THE CANE FUND.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—The journal you so ably conduct has always been an advocate for the over worked and under paid dispensary doctors. It is well known to the profession the many difficulties and annoyances to which they are subject from some illiterate members of dispensary committees. The late investigation in the case of Dr. Cane, of Mullinavatt, is sufficient argument to prove my statement. The verdict

of the Queen's Bench, in the first instance, and subsequently the decision of the Local Government Board, speak for themselves. The expense incurred by Dr. Cane in defending himself in the first instance must be very considerable; and as it is a matter which might at any time affect any one of us personally, I would suggest that a fund be raised to enable him to defray the expenses incurred in this malicious action. A small sum from each would suffice, and I am sure, Mr. Editor, that you would kindly consent to act as treasurer. I enclose my mite, which you will kindly place to the credit of the Cane Fund.

I remain, dear Sir, yours faithfully,

"ONE OF THE UNDERPAID."

[We shall be happy to receive any subscriptions with which we may be favoured for this object.—ED. M. P. & C.]

Obituary.

DR. PARKES.

WITH regret we announce the death of Edmund Alexander Parkes, M.D. London, F.R.S., Professor of Hygiene at Netley.

Dr. Parkes, whose manual on the practice of hygiene is well known, chiefly carried on his hygienic and sanitary work in connection with the army, with which he was in early life associated. From 1842 to 1845 he served as Assistant-Surgeon in the Army in India, but in the latter year he retired into civil life in England. During the Crimean war he organised and directed the working of the Renkioi Hospital on the Bosphorus, and shortly afterwards, when the Army Medical School was founded, Dr. Parkes was chosen to occupy the Chair of Hygiene. In this capacity he gained the esteem and affection of all those medical officers who, before becoming attached to the army, carried on their studies under his tuition. Truly may it be said that "his fluency and grace of language as a lecturer, together with his earnestness and kindliness of manner, won the lively attention of his listeners, while the clear yet simple style in which he described and explained the practical hygienic investigations conducted in the laboratory excited an interest in them which was attended with the most valuable results."

Dr. Parkes did not allow his labours to finish with his teaching and investigation at Netley. He was a Member of the Senate and one of the Examiners at the University of London, and a Member of the Council of the Royal Society. He was also one of the Government representatives in the General Medical Council; and it may be recollected that at the late meeting of that body he took a most active part in the warm discussion upon the question of admitting women to the medical profession. Dr. Parkes was a warm supporter of the advancement of the education and usefulness of women, and to his able explanation of the question was mainly due the carrying of an amendment which he himself proposed, "that the Council did not consider that women should be excluded from the profession."

Dr. Parkes was the adviser of the Government on all matters connected with clothing, diet, and hygiene in the army, and among other changes which he accomplished was the discontinuance of the old knapsack, for which alone he might claim the gratitude of every private soldier.

On the retirement of Sir James Clark the Queen offered the post of personal physician to her Majesty to Dr. Parkes; but he had long devoted himself to science, and he felt that such a position would be incompatible with the work which he had before him. His whole life was one of devotion to science, and the loss of such a life affects not alone his immediate friends or the profession, but the country at large. Her Majesty the Queen forwarded to him a kind message of sympathy through Sir W. Jenner, who, with Dr. Herman Weber, went down to Southampton to visit him. He died at his residence at Bitterne on Wednesday last, in the fifty-eighth year of his age.

DR. RICHARD DONALDSON.

WE regret very much having to record to-day the death of Dr. Richard Donaldson, at his residence, near Crossmaglen, on the 4th instant. The deceased gentleman had been for some time past suffering from ill health, and his decease was consequently not unexpected. He had gained a high character as a skilful physician in the district where he resided, and the poor of the locality have lost in him a true hearted sympathising friend. He was over thirty years medical officer of the Crossmaglen Dispensary, the duties of which he discharged with more than ordinary skill and very great satisfaction to the public.

Medical News.

Vital Statistics.—From the Registrar-General's return we learn that during last week 6,038 births and 3,750 deaths were registered in London, and twenty-two other large towns of the United Kingdom. The mortality from all causes was at the average rate of 24 deaths annually in every 1000 persons living. The annual death-rate was 22 per 1000 in Edinburgh, 26 in London, 27 in Glasgow, and 34 in Dublin. The annual rates of mortality during the same period in the other large towns were—Norwich 19, Hull 27, Leicester 15, Sunderland 16, Portsmouth 18, Newcastle-upon-Tyne 22, Birmingham 24, Brighton 23, Leeds 26, Wolverhampton 24, Bradford 21, Sheffield 21, Plymouth 32, Bristol 25, Oldham 28, Manchester 32, Salford 34, Nottingham 27, and Liverpool 32. The annual death-rate from the seven principal zymotic diseases averaged 3·3 per 1000 in these towns, and ranged from 0·0 and 0·9 in Norwich and Leicester, to 6·2 and 8·3 in Liverpool and Salford. Scarlet fever continues fatally prevalent in Bristol and Salford. Six more deaths were referred to small-pox in Manchester and Salford, and 7 to fever in Sheffield. In London, the 1,455 deaths included one from small-pox, 35 from scarlet fever, 18 from different forms of fever, and 16 from diarrhœa; the seven principal diseases of the zymotic class causing 201 deaths, against 215 and 227 in the two preceding weeks. These 201 deaths were 39 below the corrected average number from the same diseases in the corresponding week of the last ten years, and were equal to an annual rate of 3·0 per 1000. The deaths referred to diseases of the respiratory organs, which in the three previous weeks had been equal to 622, 458, and 405, further declined last week to 336, which were 78 below the corrected average weekly number; 207 resulted from bronchitis, and 74 from pneumonia. In the large public institutions 286 deaths were recorded, or 20 per cent. of the total deaths; of these, 175 occurred in workhouse establishments, 101 in hospitals, and 10 in lunatic asylums. The Asylum District Fever and Small-pox Hospitals at Homerton and Stockwell (which are certified for 576 beds) contained 209 patientf on the 11th inst., of which 76 were under treatment for fever, 92 for scarlet fever, and 10 for small-pox. The London Fever Hospital contained 78 patients on Saturday last (against 84 at the end of the previous week), including 64 cases of scarlet fever, 9 of enteric fever, and not one of typhus.

Royal Hospital for Diseases of the Chest.—The annual meeting of the governors and friends of this institution was held last Wednesday, under the presidency of the Lord Mayor. The report, which was read by Mr. Lowther Kemp showed that a larger number of persons had been admitted to the hospital during the past year than in any former similar period. The gross receipts were £4,389, as against £4,382 received in 1874; and the principal items of expenditure were less. Lord Charles Bruce, the chairman of the building committee, in moving the adoption of the report, said that for the large and increasing number of applicants for treatment the extension of the building was now absolutely essential, and a plan had been provisionally approved. The chairman remarked that the hospital was established by the father of her Majesty in 1814, and for 25 years was within the walls of the City of London, when it was removed to its present site. Since it was established it had relieved no fewer than 133,426 patients, and was eminently entitled to support. He next referred to the recent visit of the Queen to the London Hospital, from which he augured good results. After a reference to Mr. Attwood, who in six years had subscribed £6000 towards the funds of the hospital, the Lord Mayor put the resolution, which was carried unanimously.

The president and other officers and the medical staff were then thanked, and the meeting separated after the usual votes of thanks.

British Home for Incurables.—The anniversary festival dinner of this excellent institution, which is situated at Clapham Rise, was held last week at Willis's Rooms, St. James's, the Lord Mayor of London occupying the chair. Subscriptions to the amount of £1,165 were made in the room in response to an appeal from the chairman.

The Hospital Saturday Fund.—A meeting of the board of this fund was held on Saturday evening at the Middlesex Hospital, Captain Charles Mercier presiding. The following officers were elected:—Mr. Alderman Gould, J.P., an honorary secretary. Members of the Council: Dr. Vincent Ambler, Messrs. Moss, Deans, and Sims. Hon. secretaries of local committees were also elected *ex-officio* members of the board and council. Mr. John Napier was elected secretary, and Mr. S. T. Haley organising agent to the fund. A finance committee was appointed, together with two auditors, and the proceedings closed with votes of thanks to the weekly board of the Middlesex Hospital for the use of the library, in which the meeting was held, and to the chairman.

THE STOKES STATUE.

On Thursday last the statue of Dr. Stokes was unveiled and handed over to the care of the President, Vice-President, and Fellows of the Irish College of Physicians in the presence of a distinguished audience, not only of his professional brethren, but of the leading members of Dublin society, with the Duke of Leinster at their head. The statue is a most artistic production, and a speaking and pathetic likeness of Dr. Stokes, from the chisel of Foley, and it stands in one of the four niches of the College Hall in company with the statues of Sir Henry Marsh and Sir Dominic Corrigan. It represents Dr. Stokes in an attitude of deep meditation, characteristic of himself, and as he is borne in the memory of many of his pupils. An "*eloge*" was delivered by Dr. Hudson, and resolutions were moved by Dr. Acland, the President of the Medical Council, Professor Haughton, Dr. Hayden, and Dr. Banks, the oratory of the occasion being on the whole unusually felicitous. The committee of subscribers was represented by Mr. Tufnell and Dr. Cruise, to whom, especially the former, the whole credit is due, not only for the success of the movement, but for the satisfactory arrangement of the final ceremonial. A memorial to Dr. Stokes was a proposal which carried with it a certainty of success, for no member of the profession in Ireland has as great a claim upon the respect and admiration, not only of his brethren, but of the public. It is a disgrace to the paternal government of the country that the recognition of talents so conspicuous, a character so sterling, and principles so exalted, has been left to the bounty of individuals. Dr. Stokes has done more for his humblest fellow-man than for any of the subscribers to this memorial, and it is nothing less than a public scandal that a life of unpretentious service to the community should remain absolutely unrecognised by those whose duty it is to reward such services.

THE IRISH POOR-LAW MEDICAL INSPECTORSHIP.

We announced a fortnight since that the successor to Dr. Croker King as Medical Inspector for the Cork district under the Irish Local Government Board had been chosen. We believe we have warrant for the statement that Dr. F. McCabe, Resident Medical Superintendent of the Dundrum Central Criminal Asylum, will be the new Inspector. Dr. McCabe fulfils all the requirements which we had so strongly urged upon the notice of the Government. He has had an experience of dispensary work as medical officer of the Woodtown district, as well as in England, and has shown his administrative capacity as medical superintendent of the Waterford Asylum before his translation to Dundrum. On the whole the appointment is open to no objection, and will give satisfaction to the profession.

ATTORNEY DOCTORS.

In an action for compensation for railway injury tried last week in the London Court of Common Pleas, a receipt for £50 received in full of all claim was relied upon by the Company as barring the action. This receipt was drawn up by the doctor, a gentleman named Read, and the judge, Mr. Justice Archibald, said he must add his protest against arrangements made by medical men. He did not think them wise arrangements at all. All might be perfectly fair, but they looked oppressive. We perfectly agree with the learned judge. The closer doctors stick to their professional duties, and the less they have to say to wills or compensations, the better for the public confidence reposed in the profession.

The Council of the Royal College of Surgeons in Ireland have decided to invite his Excellency the Lord-Lieutenant to lay the first stone of the new Library and Museum, which have just been commenced. On the occasion of the former extension of the College buildings the Lord-Lieutenant of the day performed the initiatory ceremonial, and the mallet and trowel with which the stone was laid has been recently presented to the College. It is to be hoped that his Grace the Duke of Abercorn will be able to afford the *prestige* of his high position to the initiation of these works.

The 27th of April is fixed for the election of a Professor of Anatomy in the Irish College of Surgeons in the room of Dr. Morgan. The candidates of whom we have knowledge at present are Dr. Thornley Stoker and Dr. Loftie Stoney, Demonstrators in the College, Mr. Charles Robinson, a Demonstrator in the Ledwich School, and Mr. Foy, Lecturer on Anatomy in the Carmichael School.

The day of election to the vacant seat in the Council of the Irish College of Surgeons in the place of Dr. Morgan is fixed for the 6th of April. We understand that Mr. M'Dowel, of Mercer's Hospital, will not oppose Mr. Wilson, the Professor of Ophthalmic Surgery in the College. At present no other candidate is declared.

On Compressed and Rarefied Air.

From a report in the *Boston Medical Journal* we extract the following:—

Dr. B. Fränkel, of Berlin, has devised an instrument, which is made cheaply, and can be obtained by most patients for themselves. It consists of the bellows of an accordeon. On one side a metal tube is inserted, two centimetres in diameter, which carries the mouth-piece; the latter may consist of an inflated rubber cushion, similar to a pessary. Fränkel recommends the sitting position for using the apparatus. If the bellows is expanded by drawing the accordeon apart, the air contained in it will be rarefied; if it is compressed the air is condensed. If the patient, during the expansion or compression, applies his mouth to the cushion, the effect of the rarefaction or condensation of the air will communicate itself to the intra-thoracic air. The apparatus is without valves; as it is very easy to apply or withdraw the mouth from the cushion at the right moment, any such arrangement as valves is not necessary. On the margin of the apparatus there is a centimetrical measure, which plainly indicates by how many centimetres the wooden disks are separated or brought together. This shows the volume of air

which has been drawn into or expelled from the apparatus. The apparatus is thirty-five centimetres in height and sixteen in breadth. If the foldings are considered, the bottom area will be five hundred and ten square centimetres. The expansion of the apparatus of one centimetre, according to the measure affixed, would correspond with five hundred and ten centimetres of volume. Fränkel considers the attachment of the dynamometer to his apparatus as unnecessary. All excess of action is avoided, as it is worked by manual force only, Fränkel having found that with his greatest effort he could not condense the air above one-eighteenth of an atmosphere, nor increase the power of suction above one-twentieth of an atmosphere. The patient is sensitive to the amount of pressure and draught upon his lungs, and can regulate both according to his own feelings. Fränkel simply warns his patient against over-exertion.

The apparatus is easily transported, and is applicable anywhere (for inducing artificial respiration in cases of chloroform asphpxia, asphyxia of the new-born, poison by oxide of carbon, and other similar emergencies).

NOTICES TO CORRESPONDENTS.

☞ Correspondents requiring a reply in this column are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

Notice to Subscribers.—The Publishers will be glad to receive the subscriptions for the past year, 1875—£1 2s. 6d. Subscriptions in advance for 1876, at the reduced tariff of 21s. per annum, post free, must be paid before the end of this month in London, Dublin, or Edinburgh.

Reading Cases.—Cloth board cases, gilt-lettered, containing 26 strings for holding each volume of the Medical Press and Circular, can now be had at either office of this Journal, price 2s. 6d. The postal regulations not allowing the Journal to be stitched, these cases will be found very useful to keep each weekly number intact, clean, and flat after it has passed through the post.

A Poor Medical Student.—We have had our attention directed to a most deserving object for kind assistance from our professional brethren. It is that of a young man who has been always remarkable for his moral and irreproachable character, and who some years ago entered for and attended all the lectures and hospital practice to qualify for the Letters Testimonial of our College. The death of his father, and the subsequent continued delicacy of health of his aged mother obliged him to accept a situation in a medical establishment the small emoluments from which merely enable him to support his poor mother. Being of such steady and retiring habits, he has diligently pursued his professional studies, and could he but now procure the necessary funds wherewith to pay up the balances due for lectures, hospital practice, as well as the amount to be lodged previous to his being examined for his diploma, he would obtain a position whereby he could be of more assistance to his mother as well as to his sickly brother. We are assured of the respectability of this family, and of their having at one time in their native country (previous to the years in which so much Irish land property was sacrificed) held a prominent position. We will cheerfully publish receipts of any sums forwarded to us for so laudable an object as that of this poor medical student.

An Awkward Mistake.—Dr. Hassall, in his recent work on "Food and its Adulterations," referring to an analysis of the well-water from which the famous pale ales brewed by Samuel Allsopp and Sons, of Burton-on-Trent, are manufactured, states that this water contains 7·65 grains of sulphate of zinc, the fact being that no sulphate of zinc whatever is to be found in the water. Dr. Hassall's attention having been called to this erroneous statement, he has explained that for "sulphate of zinc," a deleterious mineral, "sulphate of potash," which is a natural ingredient of the purest water, should have been substituted. Dr. Hassall expresses his great annoyance that through an inadvertence upon his part so damaging a mis-statement should have been allowed to appear in his book. We are happy to give space to this explanation of Dr. Hassall.

Complimentary.—A mighty warfare of words is at the present time being carried on between the two leading papers of Sheffield—the *Telegraph* and the *Independent*. The former, smarting under an accusation of plagiarism, launches a leader of terrible invective, of which the following extract is but a mild specimen:—"He does not hesitate to take the chair at religious meetings opened with prayer. We certainly 'hesitate' to bandy words any longer with the Exemplary One who, not content with pilfering the London journals by wire before breakfast, and then boasting of his 'principle,' plumes himself on his piety, while employing his machinery to multiply an enormous mendacity and to help him to lie by steam!" Such are the amenities of editors. Let us hope ere this they are smoking the calumet of peace. Our correspondent is thanked for sending us the marked papers.

An American paper, referring to the scarcity of subjects for dissection in London, remarks: "This is an evil that will work its own cure. Let there be a generation of doctors and surgeons reared without ample opportunities of dissection, and the corresponding generation of patients will furnish an increase of anatomical material."

Doctor's Son.—You can hold an Assistancy without diplomas, and are almost as likely to get one without as with qualification. The salaries, duties, and other arrangements vary so much that we must refer you to "Via Medica," a book published by Mr. Langley, Lincoln's Inn Fields, London, W.C., which exhausts the subject.

A Sufferer.—Leishman's Midwifery. Fannin and Co., Grafton Street.

Mr. Hall, Lincoln Hospital, is thanked.

Royal College of Surgeons of England.—On Wednesday and Friday, at 4 p.m., Prof. W. K. Parker will continue his lecture "On the Shoulder-girdle and Fore-limb of Vertebrata."

Royal College of Physicians of London.—On Wednesday and Friday, at 5 p.m., Dr. Dickinson will lecture "On the Pathology and Relations of Albuminuria."

Hunterian Society.—This evening at 8 p.m., Mr. Clement Lucas will exhibit a piece of Intestine with a Diverticulum.—Dr. Hilton Fagge, "On Paroxysmal Neuroses."

Clinical Society of London.—On Friday, at 8½ p.m., Mr. Holmes will bring forward a case of "Excision of the Ankle-joint, illustrating the Utility of Linhart's Chisel."—Dr. Goodhart, "A Case of Headache, Vomiting, Double Optic Neuritis, Blindness, ending in Recovery."—Mr. A. T. Norton, "A Case of Cleft Palate; Treatment by Operation, with Artificial Uvula."

Communications, Enclosures, &c., have been received from—Dr. Lombard, Boston, United States. Dr. Despalles, Paris. Dr. Campbell Black, Glasgow. Dr. Bayes, London. Dr. Collard, Sunderland. Le Docteur E. Noir, Brionde. Mr. John Moss, London. Dr. Beaney, Melbourne, Australia. Mr. Jameson, Bagnalstown. Dr. Waudby Griffin, Southampton. Dr. Waters, Chester. Mr. MacCormac, London. Mr. Pitman, Royal College of Physicians of London. Dr. Downes, Hastings. Dr. Piffard, New York. Dr. Heagerty, Bellingham. The Secretary of the Royal Institution. Dr. Pollock, London. Dr. McGrigor Croft, St. John's Wood. Dr. Billing, London. The Secretary, Hospital for Consumption, Ventnor. Dr. Gomm, Taunton. Kew Alton Hatchard, St. Leonard's. Dr. Abrath, Sunderland. Dr. Rudolph, Birnbaum, Berlin. Dr. W. H. Day, London. Mr. Alfred Haviland, Northampton. Dr. Pearce, Atherstone. Mr. Hyslop, Stretton. Mr. E. Sanjeant, Bolton. Mr. R. Hall, Lincoln County Lunatic Hospital. Mr. Plimsoll, London. Dr. W. B. Johnston, Bermondsey. Dr. Maul, Southampton.

APPOINTMENTS.

Agar, F., L.R.C.P.L., M.R.C.S.E., L.M., Medical Officer and Public Vaccinator for the Enfield Highway District of the Edmonton Union.

Alford, G. E., M.R.C.S.E., House-Surgeon to the Weston-super-Mare Hospital and Dispensary.

Bourke, W., M.B., C.M., House-Surgeon to the Clinical Hospital, Cheetham Hill Road, Manchester.

Evans, G. H., M.D., an Assistant-Physician to the City of London Hospital for Diseases of the Chest.

Grimwood, H. C., M.R.C.S.E., L.S.A.L., Resident House-Surgeon to the Portland Town Free Dispensary.

Hamilton, J., L.R.C.P.E.I., L.F.P.S.Glas., L.A.H.Dub., Medical Officer for the Swadlincote Urban Sanitary District; and Medical Officer to the Countess of Chesterfield, Netherseal, Cadley Hill, and Heathcote Collieries.

Hobson, L. J., M.B., M.R.C.S.E., Assistant House-Surgeon to the Bristol General Hospital.

Johnson, W., M.D., L.R.C.S.Ed., House-Surgeon to the Tiverton Infirmary and Dispensary.

MacManus, G., L.R.C.P.Ed., L.R.C.S.Ed., L.A.H.Dub., Medical Officer for the Dublin and Meath Branch of the Midland Great Western Railway Benefit Society.

Parks, C. H., M.R.C.S.E., L.S.A.L., Medical Officer for No. 2 District, and Medical Officer and Public Vaccinator for No. 7 District of the St. Columb Major Union, Cornwall.

Roughton, W., L.R.C.P.L., M.R.C.S.E., House-Surgeon to the Macclesfield General Infirmary.

Sewell, H., M.R.C.S., L.D.S., Dentist to the Clergy Orphan School.

Walsham, W. J., F.R.C.S.E., Surgeon to the Royal Hospital for Diseases of the Chest.

Deaths.

Day-Goss.—On the 15th March, at his residence, Sidmouth, Devon, after four years' protracted suffering, Samuel D. Day-Goss, M.D., F.R.C.S., late of London, aged 48.

Giles.—On the 14th March, at Churchfields Place, Margate, Samuel Giles, M.D., B.A.Lond., late of Lewisham High Road, London, in his 44th year.

Hammond.—On the 7th March, at Henley Road, Ipswich, Charles Chambers Hammond, M.R.C.S.E., aged 83.

Milligan.—On the 6th March, John Milligan, M.R.C.S.E., of Whinburn, near Keighley.

Parkes.—On the 15th March, at Bitterne, Hants, Edmund Alexander Parkes, M.D., F.R.S., Professor of Military Hygiene, Army Medical School at Netley, aged 56.

Sheffield.—On the 3rd March, in his 33rd year, R. L. Sheffield, F.R.C.S.Ed., &c., Surgeon to the Metropolitan Free Hospital.

Tweddle.—On the 7th March, at Governor House, Keswick, Cumberland, John Tweddle, Esq., Surgeon, aged 44 years.

Wilkie.—On the 4th March, at Whitwell, Hants, Dr. George Wilkie, aged 74.

ON TUBERCULOSIS IN CHILDREN AND THE CONDITIONS WHICH RESEMBLE IT.

By W. H. Day, M.D., M.R.C.P.Lond.,

Physician to the Samaritan Hospital for Women and Children.

(*Continued from page* 215.)

As to the frequency with which we meet with tubercle in the different organs of the body, Steiner found the intestine involved in a third of his cases, the most frequent seat being the *small* intestine, and the least frequent the *large*. From 302 dissections made in the Prague Hospital by Drs. Steiner and Neureulter tubercle was found—

In 1	organ	in 42	cases.
In 2	organs	in 48	,,
In 3	,,	62	,,
In 4	,,	47	,,
In 5	,,	42	,,
In 6	,,	28	,,
In 7	,,	20	,,
In 8	,,	6	,,

Five times in nine cases, and twice in ten different organs.

The bronchial glands were affected in 275 cases, the lungs in 175, and the stomach in 4. (*a*) In 312 children in whom Rilliet and Barthez found a deposit of tubercle in one or more of the viscera, the lungs were healthy in 47 cases; whilst in 123 similar instances in the adult, Louis only found one such exception. (*b*)

Dr. Wilson Fox mentions 61 cases which he examined for the chief purpose of illustrating the pulmonary manifestations of the disease. All were above ten years of age, and only 2 below fifteen, and two ages not stated. In all the cases but one the lungs were affected, and in this was a combination of tubercular pleurisy with tubercular peritonitis. In 7 cases the data were uncertain; in 3 cases the disease was limited to the lungs; in 7 cases two organs were affected; in 16 cases three organs; in 12 cases four organs; in 9 cases five organs; in 6 cases six organs; in 1 case seven organs. (*a*)

M. Louis entertained the opinion that when tubercle appeared in any part of the body, it was sure to exist in the lungs also, and that the apices of these organs were the selected seat of deposit. We now know that this is by no means the universal law, which the propounder considered he had established, but it holds good with a few exceptions, and is of vast assistance in diagnosis. I have heard it asserted, and I have seen it in books also, that in every case of tubercular meningitis you will find, on examination after death, evidence of tubercle in the lungs, kidney, peritoneum, or spleen; but I am sure that twice in my life I have made a *post-mortem* of this well-developed cerebral affection without finding a trace of the peculiar exudation in any other organ or tissue of the body. And who has not met with it alone.

One of the distinctive features of acute tuberculosis according to some authorities is the appearance of the disease in many organs at one and the same time, but the statements of these observers ought to dispel the view at once. The sudden manner in which tubercular disease sometimes springs up without any obvious exciting cause, is alarmingly suggestive that an over-excited or ill-nourished organ may initiate the peculiar deposition in the track of the blood vessels, and remain there in its work of decay and destruction, having no inclination to spread and contaminate other organs and tissues. Dr. Fox mentions a case recorded by Herard and Cornil, in

(*a*) "Steiner's Diseases of Children." By Lawson Tait. J. and A. Churchill. 1874. P. 328.

(*a*) "Trans. Path. Society." 1873. Vol. xxiv., p. 375.

which the disease was limited to a single lung, and he speaks of three other recorded cases where, in addition to other lesions, one lung was affected, the other remaining free.

It was long held, that when tubercle was deposited in the lungs, that it would sooner or later proceed to a fatal issue, but repeated examination goes to prove that it is sometimes spontaneously arrested, and it has been said that this happens in one-third of the persons affected with tuberculosis. This is confined to no stage or period of the disease, it may be stopped in the early stages when the deposit is small and trifling, and instances are met with where large cavities have healed and cicatrised. "Nothing is more common," says the late Dr. Hughes Bennett, (a) "in examining dead bodies than to meet with cretaceous and calcareous concretions at the apices of the lungs more or less associated with cicatrices. Of 73 bodies which I examined consecutively some years ago in the Royal Infirmary, I found these lesions in 28. Of these, puckerings existed with induration alone in 12; with cretaceous or calcareous concretions, in 16. Since then I have examined many hundred lungs at the inspections in the infirmary, and am satisfied that the proportions exist pretty constantly. At the Salpetriére Hospital, in Paris, Roger found them in 51 bodies out of 100; at the Bicetre Hospital, in the same city, Boudet found them in 116 out of 135 bodies. Both these institutions are establishments for persons above seventy years of age." A few years ago, a young man who had a vomica in the apex of the left lung, brought me from time to time portions of calcareous matter, the size of a pea, which he coughed up with expectoration. He was greatly reduced in flesh and strength, but when I saw him last he had improved in every respect, and the cavity in the lung was apparently contracting.

. . . . . .

The following facts, according to Dr. Bennett, are proof of arrested tubercle:—

"1. A form of indurated tubercle is frequently met gritty to the feel, which, on being dried, closely resembles cretaceous concretions.

"2. The concretions are found exactly in the same situation as tubercular deposits are. Thus, they are most common in the lungs, and at their apices.

"3. When the lung is the seat of tubercular infiltration throughout, whilst recent tubercle occupies the inferior portion, and older tubercle and perhaps caverns the superior, the cretaceous and calcareous concretions will be found at the apex.

"4. A comparison of the opposite lungs will frequently show, that whilst on one side there is firm encysted tubercle, partly transformed into cretaceous matter, on the other the transformation is perfect, and has occasionally even passed into a substance of stony hardness.

"5. The puckerings found without these concretions exactly resemble those in which they exist. Moreover, whilst puckering with grey induration may be found at the apex of one lung, a puckering surrounding a concretion may be found in the apex of the other.

"6. The seat of cicatrices admit of the same exceptions as the seat of tubercles, and in about the same proportion. There can be no question, therefore, that these cicatrices and concretions for the most part indicate the arrestment, disintegration, and transformation of pre-existing tubercular exudations into the lungs."

Causes.—Of the causes of tuberculosis, and the deposition of tubercles in the lungs, the progress of medical science has not yet enabled us to speak with any degree of certainty, and the same may be said of that variety of tubercular disease, classified under the comprehensive term scrofula, with its external abscesses and disfiguring ulcerations. It is very difficult to assign the correct value to hereditary transmission from parent to offspring, regarded as a pre-disposing cause of tuberculosis, because a large proportion of the population is subject to anti-hygienic conditions, which call the disease into existence; the lives of so many young persons are passed in these days of hard toil under unhealthy conditions, that it is readily acquired, or originally induced. What is gleaned from parents respecting their family history, is frequently vague and deceptive; some will tell you that consumption is not known among them, when closer investigation satisfies us that some member of it has suffered from hip-joint disease, open abscesses in the neck, and even fatal affections of the head which must have had a tubercular origin. Instances of hereditary transmission are constantly seen in the emaciated frame of the infant whose consumptive mother barely survives the birth. When the child dies the lungs and other internal organs are so studded with tubercles that little doubt can be entertained that the disease originated at the earliest period of utero-gestation. It may be laid down as a law, having few exceptions, that the union of healthy parents results in the birth of healthy children, and that they grow up to be strong and vigorous; but when one parent is tuberculous and the other healthy, tuberculosis is apt to show itself in the offspring. As the children one after another reach a certain age they begin to lose flesh and strength, and at last die with all the symptoms of pulmonary phthisis, or tubercular disease in some other organ. The best explanation for this numerous class of cases which we observe in some families, where the victims have been carefully shielded from exhausting or depressing influences, is to be found in a blood dyscrasia, or some changes in the vessels or tissues.

Age is one of the most fertile pre-disposing causes of tuberculosis, the blood in childhood having a great susceptibility to undergo those changes which constitute the peculiar pathological transformation. We can only conjecture what the specific change is; but we do know in early life that the blood is deficient in solid constituents, and in blood corpuscles. As children grow up to maturity, and life advances, the quality of the circulating fluid is enriched, the tendency to tubercular change becomes less and less, and the power of arrest or elimination is acquired if the constitutional strength can be maintained. It may be that the diminished number of red corpuscles in chlorosis and anæmia is one reason of their fatal termination being frequently accompanied by the deposit of tubercle and the gradual development of phthisis. For an illustration of this, I may refer to the number of young women who seek advice at our hospitals for amenorrhœa and arrested catamenial losses under the belief that the cessation of uterine discharge is at the root of their disorder, when in reality the true cause is attributable to an altered condition in the physical characters of the blood, which can no longer bring sufficient stimulus to bear upon the uterine function.

The effect of intermarriages in the spread or freedom from the disease has been well pointed out by Sir William Jenner. (a) "That tuberculosis is transmitted from parent to child, is one of the best established facts in medicine. The extreme frequency of tubercular diseases in some circumscribed country districts is, in part at least, explicable by the frequency of intermarriage amongst persons living in such districts; and conversely the exception of particular circumscribed districts from tubercular disease is due to the same cause; in one case, from some special circumstance, tuberculosis has been introduced into the district, and then spread in it from the cause I have mentioned, *i.e.*, intermarrying; in the other case, the freedom from the disease of the district, at any given time, is the cause of its continued freedom. Intermarriage of the inhabitants, the disease being absent, prevents its introduction.

Where hereditary transmission is so strong (and that it is so daily experience affords the most conclusive evidence), the germ of the disease either lies in a latent state,

(a) "Braithwaite's Retrospect." Vol. xlviii., p. 55. 1863.

(a) Address before the Epidemiological Society of Lond., 1865.

or is actively transmitted by the parent. Rilliet and Barthez furnish some interesting facts to the effect that, "of 26 children whose fathers were tuberculous, or *probably* so, 22 died tuberculous, and 4 non-tuberculous; of 32 children whose mothers died tuberculous, or *probably* so, 22 died tuberculous, and 10 non-tuberculous; of 6 children whose fathers and mothers died tuberculous, 4 died tuberculous, and 2 non-tuberculous. There were 46 cases, or about 1 in 7, in which the hereditary influence more or less prevailed, and 11 in which it was the sole probable cause." (*a*) There are many points of extreme interest on this part of the subject which I cannot now pursue, such as the relative frequency of its transmission by the two sexes, and the manner in which this takes place.

Children brought up by hand, and weaned too soon, or neglected by the mother, are very liable to the disease. A case is related by Meggs and Pepper (*b*) of a healthy woman, who had several vigorous children whom she had nursed. She gave birth to one which she could not nurse, and this child, after pining for many months, died of tubercular meningitis.

Bad or insufficient food, leading to prolonged indigestion and diarrhœa, exext a powerful influence in the production of tubercle. Artificial foods of all kinds, when too exclusively relied on, may awaken the disease; and defective nutrition and mal-assimilation, however brought about, are common causes of tuberculosis in those who are not even pre-disposed to the affection. The eruptive fevers and whooping-cough frequently act as a starting point; the disease having an admitted tendency to spring up after these acute affections. The continuance of febrile action is liable to alter and deteriorate the quality of the blood, and to render it susceptible of tubercular change. If we look back in memory only to our experience of the number of children who have exhibited symptoms of tuberculosis, as the consequence of febrile disorders, we are in a great measure driven to embrace the doctrine that such diseases as whooping-cough and measles not infrequently originate the disease in constitutions, neither innately consumptive, nor hereditarily tainted. It is highly probable that these two zymotic affections have this formidable termination, because the pulmonary organs rarely escape some degree of implication.

In those cases in which pneumonia and bronchitis are associated with tuberculosis, it is a disputed question whether the inflammation is a secondary affection, or whether it has been the essential and true cause. Both views have some show of reasoning, and I shall therefore consider the subject at some length. We may repeatedly witness children whose general health fails for months together, when the physical signs afforded by auscultation and percussion reveal no evidence of abnormal change in the pulmonary organs. The disease may advance considerably before they afford any evidence of alteration, and we may have extensive tubercular deposit, which is unsuspected by us.

The plasma exuded in states of acute inflammation bears an almost identical resemblance to that which is poured out in low forms of disease happening to cachectic and tubercular subjects. The essential difference consists in the former case of its vital endowments, or capacity for higher organisation, whereas in the latter it has no power to advance in this direction, and the exudation remains much in the same condition as when it was first secreted. The physical and general signs, too, between a case of chronic pneumonia in a weakly person, and tubercular infiltration are so closely allied, that notwithstanding that the history and progress of the two affections may be some guide to diagnosis, they constantly fail to put us in possession of any conclusive evidence. Now, it is worthy of notice that a general cachexia regulates the anatomical character of all these exudations, and that in the absence of any apparent exciting cause there has still been a factor in operation, which deals a fatal blow to the doctrine of spontaneous origin. The children of consumptive parents may bear characteristic proofs of the disease, but all do not die of phthisis—some may attain to a ripe old age, and others as they reach maturity drop off one by one. Every child bears traces of the constitutional diathesis in the delicacy of form, accelerated circulation, and general appearance; but some have escaped the circumstances which call tuberculosis into action. The different functions of the body are languidly carried on, and enough nourishment is appropriated for the maintenance of life; or from some unforeseen causes (ever ready to come into operation) a period arrives when an inflammatory affection of the lungs, or some other part springs up. Through perverted nutrition, the exudation or effusion of coagulable lymph takes piace, and local disease is initiated. Here is an argument suggesting the probability of a new power or agent, suddenly altering the nutrition of an organ; but it may be contended, with equal force of reasoning, that the exudation was there slumbering and undiscovered, and only required the stimulus of external causes to rouse it into action. I think strong arguments may be adduced on either side. It is both certain and evident that the earliest signs of inflammation should be watched for in those persons who manifest the tubercular cachexia; and it will, I think, accord with the experience of most physicians when I add that there is a susceptibility to irritation and congestion of the pulmonary organs from trivial causes in these cases, similar to what occurs in the different textures of the body, when the blood is contaminated by the detention of noxious elements, which the impaired or damaged secretory organs are unable to eliminate from the system.

ON A CASE OF CONCEALED ACCIDENTAL HÆMORRHAGE. (*a*)

By J. Ashburton Thompson,

Fellow of the Obstetrical Society of London; Surgeon-Accoucheur to the Royal Maternity Charity; Surgeon at King's Cross to the Great Northern Railway Company.

I propose to address you upon a rare and very fatal complication of pregnancy, to which the appropriate name of "Concealed Accidental Hæmorrhage" has been given by Dr. Braxton Hicks. That name sufficiently imports the nature of the complication; but probably, until it was pointed out, one would not be prepared to find that the symptoms to which retention of the discharge gives rise differ essentially in mode of occurrence, in kind, and in danger, from those of accidental hæmorrhage of the ordinary sort. Yet such is the case. In the latter hæmorrhage the symptoms which arise are those of hæmorrhage simply; and as on the one hand a little accidental hæmorrhage is not uncommon in the course of ordinary labour, so, on the other, the patient does not suffer in that case except in proportion to the amount of loss. But when the discharge is concealed the case is widely different. In the first place, although the cause of the hæmorrhage is similar, it is not identical. There is separation of the placenta, it is true; but the separation is what has been called a central separation—that is, the attachment of the organ to the uterus by its rim remains intact, the effusion being confined between it and the adjacent part of the uterus, and hence *concealed*. Thus it is plain that the amount of hæmorrhage which can occur at this period is but small, and it might even be asked whether (beyond the death of the fœtus and the induction of labour) any symptom of consequence would occur. Yet the result of so small a loss is immediate syncope, which (unless the symptoms be relieved) passes on to collapse, and quickly ends in death. In the meantime the

(*a*) Read before the Harveian Society of London.

case is obscure; very often the collapse is the only obvious symptom, although pain is sometimes added; and frequently the case bears the closest possible resemblance to one of laceration of the uterus. The remedy lies in taking those steps which will most speedily ensure delivery; every moment of delay adds immeasurably to the patient's already imminent danger, and it appears that Nature is not able to accomplish much under these circumstances, for if the patient be not delivered she will die. I will first of all show you that the subject has been rarely discussed.

In 1860 Dr. Hicks read a paper before the Obstetrical Society of London in which he stated that after a lengthened search he had, up to that date, been able to find reports of fifteen cases only, and among them were three —the only cases which had occurred among twenty-two thousand consecutive labours attended in the maternity department of Guy's Hospital. To these fifteen cases he added seven, up to that time unpublished, and collected by him from private sources, together with the one he himself had witnessed, and which was the occasion of his essay. In 1868 three more cases were reported to the same society by different Fellows. Next, in 1870, Dr. Goodell, of New York, published a paper in which the literature of this subject is exhaustively summarised; and although he fully concurs in the general belief that such cases are extremely rare, he has yet succeeded in collecting as many as 106 from various sources, where they were often detected under other names, or, no post-mortem examination having been made, were recorded as obscure cases of sudden and fatal illness during pregnancy. Many of them were supposed cases of spontaneous rupture of the uterus, to which, as I have said, accidental hæmorrhage bears a close resemblance, and I propose presently to endeavour to point out some of the signs by which one accident may be distinguished from the other in doubtful cases. It was only by indefatigable industry, and a labour which those only can properly estimate who have been engaged in a similar search, that Dr. Goodell was able to collect so many examples. But in proof of the rarity of the subject, I will repeat some facts which he cites to the same end. Mesdames Boivin and Lachapelle denied the possibility of accidental concealed hæmorrhage. So did Velpeau. Blundell, Churchill, Cazeaux, and Burns never saw a single case. Lastly, to adopt Dr. Goodell's own words, the manner in which this complication is spoken of in every work upon obstetrics, except that of F. Ramsbotham, is historical, and not clinical. What Dr. Goodell wrote in 1870 still holds good. There is indeed in the last published System of Midwifery a scant description of the symptoms of concealed accidental hæmorrhage; but it has not received, as so obscure a complication deserves to receive, a separate section to itself, and the directions for treatment are mingled with those for the treatment of ordinary accidental hæmorrhage, if indeed it can be said that any distinction between the two is made.

In 1875 Dr. Brunton communicated to the *Obstetrical Journal* of Great Britain an account of five cases of this kind with which he had himself met, and to the above cases I now add the one which I am about to repeat to you. In showing the fact of its rarity, and in asserting that no adequate description of this complication of pregnancy is to be found in any English work upon obstetric medicine, little or no reference to it being made in most books, I trust I have shown, too, that the subject may not unprofitably occupy our attention this evening.

Case.—A tall, thin, large-boned woman of lymphatic temperament was seized with pain at about two weeks previous to the termination of her seventh pregnancy. She had not suffered any shock. At five o'oclock in the evening she began to suffer from "cutting" abdominal pain, which, though somewhat different from that usually suffered at the beginning of labour, was not distinctive enough to alarm her. At nine o'clock she was found apparently in the early stage of a normal labour. She made no unusual complaint, presented no unusual appearance, and was experiencing slight throes every few minutes. The os was about an inch in diameter, thick, and a little hard; the membranes were entire, and the vertex presenting. At ten o'clock I found her lying on her back; and I was informed by the nurse that my presence was desired not so much on account of the progress of the labour as shown by the throes (which were not severe) as on account of the complaints of persistent pain which the patient constantly made. I desired her to turn over on her side, which she promised to do as soon as her pain went off, and I therefore sat down to wait a few minutes. I soon perceived that she was suffering from continuous pain, to which every now and then a feeble throe was added, and I therefore hastened to make a vaginal examination. I found that there was a trifling external hæmorrhage, including a small clot of about half an ounce in weight; the os dilated to a diameter of two inches, but still rather unyielding and thick; and the membranes extremely tense. Prolonging the examination during two throes, I observed that the membranes maintained a uniform tenseness, and on examining the uterus externally, I found that it too was curiously hard, well defined, and incompressible; that it was impossible to make out the fœtus through it, and that it was extremely tender. The patient continued her constant complaint; she began to get pale, restless, and anxious, though far from collapsed, and the pulse rose to 120, at the same time that it became very feeble. On recognising these symptoms it was not difficult to diagnose the existence of that kind of hæmorrhage known as the "concealed accidental"—a rare form, and one but very seldom described. Being careful, in the first place, *not* to rupture the membranes, a large dose of brandy and ergot was given, and dilatation of the os assisted as far as possible by the finger. It yielded more rapidly than I expected; the membranes began to protrude a little into the vagina—but not much, for they always remained tense—and at last they broke, a small quantity of colourless *liquor amnii* escaping. The head immediately occupied the os, and three fair throes ensuing at short intervals, the child was expelled. Assisting the delivery with the left hand, I followed the uterus down as it contracted with the right, and as soon as the child emerged a little pressure immediately expelled the placenta, together with a large quantity of blood, both fluid aad clotted. The child was dead, but not blanched; the placenta was normal in appearance, but showed evidence of its separation in a thin pellicle of clot spread over nearly its whole surface; it was without the central depression frequently observed in such cases. The discharge consisted of about one pound of fluid blood, and one and a-half pounds of clotted blood, of which the greater part was very firm and solid. The uterus contracted well, and altogether there was not more than half-a-pint of post-partum hæmorrhage; yet the patient, who for about five minutes after delivery had appeared pretty well, soon passed into collapse. Dr. Brunton, for whom I had previously sent, now arrived, and by our united exertions we succeeded in saving the patient after she had shown the various symptoms usually attendant upon severe hæmorrhage—paleness, cold, restlessness, disturbance of vision, incoherent muttering, vomiting, intermittence and temporary complete failure of the heart's action, and the rest, from which repeated doses of egg and brandy, sinapisms, warmth to the extremities, and so forth, recovered her after about an hour and a-half. The pulse was carefully watched the whole time, and presented the following phenomena at minutes after delivery:—5 minutes, 120, fair, irregular (irregularity of the pulse is frequently observed after normal delivery, continuing for a considerable time); 20 minutes, 126, large, soft, feeble; 25 min., 112; 30 min., 108, a little firmer, but intermitting every fourth beat; 45 min., 80, very soft and large again, intermittent (vomiting began); 50 min., 78, still intermitting; 55 min., 72, of bad quality, but not intermittent; 80 min., 93, and normal—that is, though irregular, almost recovered in point of force and tension.

She then slept for five minutes, and woke up again very

much better, and with a natural appearance. She took milk, egg, and brandy, and an hour and a-half afterwards was found with a pulse of 64, very small and weak, not quite so well as at the last observation, but safe for the time. Twelve hours afterwards she was pretty well, with a pulse of 120, of fair quality, and she made a good recovery.

From what I have already said, it may be thought that this subject has been sufficiently handled of late to render any further discussion of the symptoms and treatment unnecessary; yet I believe it still remains to write a classical description of a case of accidental concealed hæmorrhage. This I do not propose to attempt; but to examine the various symptoms with a view of ascertaining what, if any, are really diagnostic, and of arranging them in their order of frequency and of occurrence. It remains to settle a line of treatment to be pursued, for some difference of opinion exists upon a point which, barely stated, may appear trivial, but which is, in fact, of great importance—the time of rupturing the membranes.

The chief symptoms of Accidental Concealed Hæmorrhage are seven in number, viz. :—1. Faintness or syncope, and collapse. 2. Constant uterine pain. 3. Deficiency of the throes. 4. Tenseness of the membranes. 5. Persistence of this tenseness between the throes. 6. Alteration of the uterine tumour in (A) shape, (B) size, (C) quality. 7. Tenderness of it. These symptoms were all present in my own case, which was therefore a particularly clear one, and I shall consider them in the order in which they are set down. For statistical corroboration of any assertion I may make I shall depend upon an analysis of thirty-three cases which I have made, comprising Dr. Hicks' twenty-three, the eight others to which I have referred, my own, and one from the *New York Medical Journal* for 1848, upon which I fell by chance. Occasionally I shall refer to Dr. Goodell's cases, among which the last is included.

Faintness or syncope is the constant symptom of the onset of this kind of hæmorrhage. It is constant because it does not depend upon the amount of blood effused. If it were a truly hæmorrhagic syncope it would be absent in those cases in which the effusion was small in quantity. Case 2 is a striking example. The total effusion was no more than half a pound; yet the patient was taken with sudden syncope, rapidly became collapsed, and died quickly. Case No. 33 is no less remarkable; for the same sequence of events was observed, although the total effusion was only 17 oz. In cases 25 and 26 (in both of which the patients died) the effusion was a pound and a half and from that quantity to two pounds respectively. When there are repeated effusions the patient may faint under the first, and recover for two or three days, and then succumb to a second attack. Such are cases 13 and 25. This syncope runs on to collapse in every case, but sometimes there is no noticeable stage of mere fainting, and sometimes on the other hand collapse only sets in after delivery. My own case is an example of this, and case 24 is another. A comparison of the whole number shows that in seventeen collapse supervened upon the accident at once, or set in with great rapidity; while in fourteen it advanced slowly; in the remaining two not occurring until after delivery. Fainting at the onset and collapse at some period or another, but most often at an early period, seem then to be constant and therefore essential symptoms of this accident. Vomiting, diarrhœa, colic, and tympanitis, are occasional attendants upon this symptom, just as they are upon collapse from other causes—rupture of the uterus especially. But they are not frequent symptoms, and would require but little notice here were it not that occasionally they have been (after the fainting) the only prominent symptoms, thus leading to their being mistaken for the primary disease. Dr. Goodell's own case is a noteworthy example of this. He says that even now he is unable to say whether the vomiting were the cause or the effect of the hæmorrhage. Of course vomiting, like any other sudden and violent muscular exertion, may separate the placenta; and for that reason its occurrence during pregnancy is always looked upon with apprehension if it be violent. As a symptom of internal hæmorrhage, alone it is of no value. It may, on the other hand, act as a very serious obstacle to the diagnosis of a doubtful case, and most especially if it should be accompanied by colic and meteorism, for both of these are not infrequent concomitants of rupture of the uterus.

Since the small quantities of blood above described are not sufficient to have caused collapse (and much less therefore the death of the patient), from hæmorrhage, it becomes necessary to look for some other explanation of these events. It is to be found, I believe, in the sudden tension to which the uterine wall is subjected. Yet it appears from the circumstances of some of these cases that the walls of the uterus are dilatable with ease; that is to say, that being filled with the entire ovum, yet an "enormous"—such is the term used—an enormous quantity of blood was found within it in addition, after death. It is still not plain, therefore, how half a pound of blood could exert pressure enough to cause serious distress. Accordingly it will be found that all those cases in which a comparatively small effusion caused sudden collapse were cases in which the blood was confined between the placenta and the adjacent portion of the uterus; the centre of the former alone being separated, a sac was thus formed of such capacity that to accommodate even a small clot the uterus must have given way to an extent disproportionate perhaps, at that particular part, to the distension it suffers when there is a larger effusion spread over a wider surface. In these cases the placental tissue is found hollowed out, or flattened and condensed, or sometimes even ruptured by the pressure. It is this sudden stretching of the uterus which in all cases conduces to the collapse, and in some, in which the hæmorrhage is inconsiderable, causes it; and that is the reason that collapse is a constant symptom of concealed hæmorrhage.

Stretching of the uterus, or a part of it, which is competent to cause collapse, must also in every case cause pain too. This is the second symptom of concealed hæmorrhage. In addition, this pain bears a particular character in that it is a *constant* pain—continuous and quite independent of the throes, although it is aggravated by them. It was its continuousness which first attracted my attention in my own case.

In every case of the thirty-three which I have analysed in which any positive note is made upon this point, with only one exception, pain was present—that is to say, in twenty of them. This statement coincides exactly with that which Dr. Goodell makes—wherever anything is said about pain it is noted to have been present. And I think his farther remark may be endorsed—that in that case in which it is clearly stated there was no pain it is probable the attendant arrived after collapse had occurred, when every symptom dependent on the sensations of the patient was necessarily absent. The obvious cause of the pain makes it probable also that that symptom was present in those cases in which nothing, either one way or the other, is said about it. So again, with regard to the continuous character of the pain, I find that in every one of the twenty in which its character is referred to at all—that is, in sixteen—it is said to have been constant; and we are warranted in inferring that had it been observed it would have been found constant in the remaining four. I am therefore inclined to consider continuous pain as a constant symptom, and therefore an essential symptom of this form of hæmorrhage, depending as it does upon the same cause as those other constant symptoms syncope and collapse; the last-named condition alone being competent to hide the pain, as above remarked. The seat of this pain is of course the uterus, but it is not always referred to that part by the patient. It is sometimes felt in other parts of the body as well—the back and hips, and in one or two cases it has been referred to these parts alone. It is very frequently described by the patient by that term which one would

expect upon a knowledge of its cause—as a bursting pain; eight out of twenty used this term. When the patient volunteers that she feels as "though she would burst," that expression affords a diagnostic between the pain ensuing on rupture of the uterus and that under consideration. But often the patient describes it in other ways; my own patient called it a tearing or cutting pain, and objected at once to its being called "bursting." In that case the pain comes nearer in kind to that which follows on rupture, but its diffusion over the whole uterus and indeed its severity too are points of difference between it and the latter. Occasionally tenderness of the uterus is noted, and that is another symptom which I feel inclined to think ought to have been noted much oftener than is the case. Tenderness is said to have been present in but five of the thirty-three cases. But it is over-distension which causes the continuous pain; and, since the uterus is filled with contents which are in great part fluid, pressure upon any part of it must cause such an increase of pressure at every part of it as shall increase the pain too. Tenderness is "pain upon pressure;" hence I think that tenderness would have been oftener observed had it been looked for.

The feebleness or absence of uterine contraction is another sign which may be regarded as constant. Most often, as I have before observed, if not invariably, this kind of hæmorrhage precedes labour; it excites labour, much as the injection of warm water between the uterus and membranes excites it. Hence in some cases it will be found that the throes are absent because labour has not begun. Should the case be watched for a time, it will presently be observed that some feeble throes are superadded to the continuous pain. They may recur with regularity, yet they are always very slight, and appear to gain nothing in force as time goes on; nevertheless, for the same reason that the uterus is tender they may cause excruciating accessions of pain, and so simulate those throes attendant on rupture which are said to be excruciating. Two causes are in operation in these cases to diminish the uterine action; they are, over-distension of the uterus, and collapse. Upon the former I need scarcely make any observation. But I may remark that there is nothing so inimical to uterine contraction as collapse; and that is best illustrated by a reference to uterine action in cases of rupture. In the case of that accident—upon which it is commonly asserted that the throes stop abruptly—I have recently shown that (subject to evacuation of the organ either by the natural channels or into the abdomen) the force and frequency of the throes vary in an inverse proportion to the amount of collapse, invariably. It will therefore fall to be considered, in discussing the best method of treatment, how far rupture of the membranes may be depended upon to overcome, not only the paralysis of over-distension, but the collapse which results from it as well. In diagnosing a case, then, in which the throes are absent, consider whether the collapse be such as will account for their absence; for, if it be not, there is some other cause at work which is not a mere rupture. That, *per se*, has no influence over the uterine contractions. Yet another point of differential diagnosis may be mentioned here, and that is, the almost invariable occurrence of the symptoms of this kind of hæmorrhage before labour sets in. Without denying that laceration of the gravid uterus does occasionally occur before labour, yet that is a very rare circumstance; and unless direct violence have been inflicted, it is far more probable in any given case that hæmorrhage, and not rupture, is at the bottom of the train of obscure symptoms which has attracted attention.

Although the throes are absent, that does not prevent a very thorough and speedy dilatation of the os, such as is witnessed in many a normal labour before a single expulsive pain has been experienced. The hæmorrhage and the collapse both favour this relaxation of the lowest zone of the uterus, and afford, indeed, the only advantage which can be taken in dealing with these cases. Even in examples in which the os has been but partly dilated, when the membranes were ruptured its expansion has been completed under comparatively feeble pains in a truly surprising manner. This is a most important point to recollect in treatment.

Clinical Records.

MEATH HOSPITAL REPORTS.

CASES UNDER THE CARE OF

LAMBERT H. ORMSBY, F.R.C.S.,
Surgeon to the Hospital.

CASE I.—*Recto-Vesical Fistula.*

NICHOLAS M——, æt. 58, was admitted into the Meath Hospital on the 16th April, 1875, suffering from a very tight stricture of urethra, and a fistula communicating with the bladder and rectum, through which the greater part of his urine passed per rectum.

History.—States that he was in the Royal Irish Constabulary for many years, during which time he was subject to all the vicissitudes of his calling, being out in all weathers, subject to wet and cold; was on the whole a very temperate man. About two years ago he fell across a beam of timber and received a severe contusion in his perinæum, from which he apparently recovered in the course of a few weeks, without any bad effects, such as extravasation of urine, perineal fistula, &c. Ten months after the injury he noticed he did not pass his water as free as usual, and required much forcing to completely empty his bladder, at the same time noticing the stream considerably diminished in size. He then applied for relief, and a silver instrument (No. 4) was passed with much difficulty into his bladder. This treatment was continued for some time, until he moved to another part of the country, away from advice, and he allowed the stricture to be neglected. About a month or so after this he noticed when he attempted to pass water a great dampness and moisture appeared to issue from the anus. After a week he noticed the urine began to pass through the rectum whenever he went to pass water, and this continued to flow in variable quantities up to the time of admission into hospital, when he was carefully examined, and his perinæum appeared perfectly healthy, no appearance of fistula or abscess; the urethra was then explored, and two very tight strictures detected, one in membranous portion of urethra and the other two inches from orifice, which allowed a gum elastic catheter (No. 3) to pass with much difficulty and manipulation.

Treatment adopted.—Mr. Ormsby, on examination per rectum, was able to feel a small papilla very high up, in the gut, corresponding to the rectal opening of the fistula, through which the majority of the urine passed, and thus putting the patient to great inconvenience, as on each occasion of his requiring to empty his bladder he had to take down his trousers or allow them to be saturated.

A gum elastic catheter (No. 3) was then passed into the bladder and ordered to be retained for a couple of hours.

April 21st. Less urine passed through rectum when catheter (No. 4) was introduced: this plan of gradual dilatation was continued every second day, when a larger instrument was used, sometimes with success, at others the same size was only found practicable.

On April 30th passed catheter (No. 6) into the bladder, and for the last two days he found very little water passing through rectum. Two days after he did not find any, and the treatment was still continued for a fortnight longer, when catheter (No. 8) could be passed with great facility, and he can now pass his water with a full and easy stream. His condition continued to improve, and he was discharged about the middle of May in perfect

health. He has since been heard of, and was then quite well, and had no return of the fistula, &c.

Mr. Ormsby mentioned to his class, when talking of this case, how very important it was when exploring the urethral canal to use the greatest tenderness and care during the passage of a catheter into the bladder, and particularly so when a metallic instrument was used. In fact, in inexperienced hands, a gum-elastic catheter, rather than a metallic one, in all cases had better be introduced, and anything approaching to force in the introduction of an instrument he condemned very strongly, and mentioned it was frequently attended with a very serious set of complications. Recto-vesical fistula had occurred before now from such a cause, in others it had followed after tapping the bladder through the rectum, or people sitting on a sharp splinter of wood, or an iron spike which passed through rectum and bladder; at the same time, in cases that were complicated with tight strictures, the indication evidently was to cure the stricture, and the urine would always more likely pass by its natural passage than otherwise, as this case so satisfactorily demonstrated, for on the stricture being dilated nearly to its natural size the urine ceased to pass through the rectum, and the man has continued well ever since.

CASE II.—*Lacerated Urethra.*

Dennis M——, æt. 35, occupation a currier, was admitted into hospital on the 7th of April, 1874, suffering from internal laceration of urethra.

History.—On the day before he stated he was in a row with some others and was kicked and knocked down, receiving at the same time a very severe kick in the perinæum and base of penis. He suffered great pain, and tried to pass water immediately after getting up, but found he could not, but saw a great quantity of blood issuing from end of penis.

State.—On admission he complained of very great pain, was rather collapsed, said he had a great desire to pass water, but that it gave him such excruciating pain that he feared to make the effort. The penis and scrotum were very much swollen and ecchymosed, and blood was still passing from the urethra.

Treatment adopted.—He was immediately put into a warm bed and an india-rubber flexible catheter (No. 10) gently passed into the bladder, and a considerable quantity of bloody urine drawn off. This catheter was then left in the bladder—20 drops of tincture of opium in 2 oz. of camphor water administered to prevent or anticipate any rigors that might arise. The man then slept for a couple of hours, and said he felt much better after his sleep. The plug was taken out of end of catheter, and more urine passed mixed with blood. Perinæum carefully examined to detect if present any bulging of extravasated urine; no appearance of such being present.

April 9th.—He expressed himself much better, pain considerably less, catheter removed, cleansed, and re-introduced, when the urine flowed freely through it, a little blood still mixed with it, but no sign externally or constitutionally of extravasation of urine.

April 13th.—Much better, pain less, no blood now in urine; says he has pain at night. Ordered 15 grains of hydrate of chloral in 2 oz. of infusion of hops.

April 14th.—Catheter removed, as the swelling in the penis and scrotum had nearly disappeared, and no blood had passed from the urethra for last three days.

From this time he made a rapid recovery, and left the hospital in about a fortnight without any pain or annoyance in passing his water.

Mr. Ormsby mentioned, with reference to this case, that lacerations of the urethra were lesions that required at times very prompt and active treatment, owing to the grave consequences that may occasionally arise after the receipt of such an injury. The danger of extravasation of urine is one that the surgeon must always bear in mind, and the treatment should be so regulated as to anticipate or prevent such an occurrence. A flexible catheter passed into the bladder and retained is a most important point in the treatment, so as to allow all the urine to flow through the instrument and not to come in contact with the lacerated mucous membrane of the urethra. As regards retaining the catheter, there is sometimes a difficulty when retained by plaster or with tapes, the urine flowing through the catheter wetting the tapes and plaster, which allows the plaster to become loose and the catheter slips out. This can be all obviated by using a most ingenious india-rubber noose, that is attached to the end of the catheter, and embraces the penis, never slips, retains the instrument perfectly; water does not affect it; it is flexible, to allow distension of penis, &c., and is purchased for a trifle at any surgical instrument-maker's.

Lacerations of the urethra are frequently followed on healing by contraction and induration, which is very often the starting point of very troublesome and intractable stricture.

Transactions of Societies.

CLINICAL SOCIETY OF LONDON.

SUCCESSFUL CASE OF GASTRO-ENTEROTOMY.

MR. MAUNDER read an account of a case of intestinal obstruction which he had attended in consultation with Mr. F. Gordon Brown. The patient, a male, 63 years of age, of costive habit, passed some blood on two occasions *per anum*, without any apparent, cause, about six weeks before coming under observation. He had also for some months suffered from borborygmi. His general health had not been good, his pulse being feeble and intermitting. He had had occasional attacks of gout. On October 23rd, 1875, he consulted Mr. Gordon Brown for constipation and great uneasiness in the bowels. A mild aperient relieved him. On the 28th he saw Mr. Brown again, and made a similar complaint. On examination the abdomen was distended and tympanitic, especially in the centre, while the regions occupied by the colon were markedly flat. A tumour could be detected on deep pressure, situated somewhat to the left of the umbilicus. The patient looked anxious and felt sick. Two senna draughts were administered, and he had previously taken a large number of aperient pills. The next morning he was no better, and he complained of great pain round about the umbilicus and towards the right iliac fossa. The pain was paroxysmal, recurred constantly, and was excessive. Temperature, 97.5 deg.; pulse, 68, as usual. On October 29th, at 2 p.m., Mr. Maunder saw the case. Hiccough had set in; a copious stimulating enema was administered. In the evening the pulse was 100 and feeble; the pain in the abdomen was severe, and the tenderness had increased towards the right side. On October 30th an O'Bierne's tube was introduced, and about five pints of warm water, medicated with a little brandy, were readily injected, but without satisfactory result. Mr. Maunder agreed with Mr. Brown that the large intestine was empty, and that the cause of obstruction was very likely a growth seated in the wall of the bowel, and probably somewhere about the lower part of the ilium. Belladonna suppositories were ordered, and seemed to give relief to physical pain and to procure sleep. Hiccough continued. On October 31st the patient was no better. On November 1st the bowels were still unrelieved. There was no flatus. Vomiting commenced. Tympanites had increased. Hiccough continued. Possible relief by operation was suggested, but declined. On November 2nd the patient wss weaker, with an anxious sunken countenance. The abdomen was more distended, jutting forward at the umbilicus. He still vomited. Small hopes were entertained of his recovery. On November 3rd he had rather gained ground than otherwise. Dr. Strange Biggs (a relative of the sufferer), having joined in consultation, it was agreed—the patient having consented—to make an artificial anus in the small intestine in the right iliac region; and at 3.30 p.m. the operation was performed by Mr. Maunder. Somewhat below the level of a line drawn between the antero-superior spine of the ileum, on the right side, and the umbilicus, a longitudinal incision was made about an inch and a-half long, over a coil of distended bowel, dividing layer by layer, skin, fascia, muscles, and, lastly,

peritoneum to the extent only of some three-quarters of an inch. Bowel now presented, but did not protrude in the least. To allow it to do so in order that some superficial sutures might be introduced to fasten it to the margin of the wound, a minute opening was made into it with the point of the scalpel to set free pent-up gas. This rapidly escaped, and, as the bowel began to collapse, the operator seized it with the aperture in it with a pair of forceps, and, drawing the viscus slightly forwards, gave it to his assistant (Mr. C. F. Hawkins) to hold, while he introduced on each side a fine suture. Three silver wires, to be converted hereafter into six sutures, were passed through the edges of the wound and across the bowel, and then this latter was opened in its long axis sufficiently to admit the point of the index-finger. A large quantity of gas immediately escaped, and was soon followed by an abundant flow of semi-solid rusty black fæces. Immediately after the operation the temperature was found to have dropped 1·5 deg. Sickness and hiccough had ceased. At 11 p.m. the patient expressed himself greatly relieved by the operation. On November 4th, at 10 a.m., the patient was found to have slept well during the night. His pulse had varied from 60 to to 100. The abdomen was flattening. At 10 p.m. he had passed a comfortable day. His temperature was 97 deg., pulse 60. He had eaten some bread and butter. On November 6th the patient took his nourishment well. His temperature was normal. November 16th.—He sat up out of bed on this the thirteenth day after operation. On December 17th he had gained flesh, and said he was in better health than he had been for many months. The passage of fæces was controlled by a hollow india-rubber plug, devised by Mr. Brown for that purpose (similar to one exhibited). It was worn within the bowel without the least inconvenience. Mr. Maunder remarked that, for the moment, the history concerning the persistent sluggish nature of the patient's bowels led one to hope that an accumulation of fæces might be the cause of his discomfort; but the absence of distension in the line of the colon, and the ready injection of five pints of fluid with small material results, quickly dissipated this hope, and likewise compelled one to accept for the seat of obstruction probably a point not lower in the alimentary canal than the cæcum, possibly higher. The nature of the obstacle was doubtful; but the fact that the anus and the rectum were both healthy, and that the patient had never had hæmorrhoids, and yet that, on two occasions recently, blood had been voided, coupled with the fact that a tumour could be made out with moderate distinctness (the existence of which had been confirmed since the operation), led to the suspicion that a growth, probably malignant in character, had invaded the wall and obstructed the channel of the intestine. Again, the absence of great distension and the comparatively early vomiting, made it reasonable to believe that the obstruction was not lower than the point already indicated. At the same time, the disease must be regarded as chronic in its character, and certainly non-inflammatory, the temperature never being above normal. And thus it was possible to eliminate as possible causes of obstruction every variety of internal strangulation and ileus. With regard to treatment, very little was advisable, and that little without much hope of success. Supposing the calibre of the bowel to be narrowed by a growth in its wall, there yet might be a channel along which fluid, but not solid, fæces could pass, and, with that view, belladonna and sulphate of magnesia were administered. Vomiting having set in, the patient was fed by the bowel alone. On the next day, having rallied, an immediate operation was urged as his only chance. The operation was somewhat similar to that which Mr. Maunder advised in another case in 1872 (*Medico-Chirurgical Transactions*, vol. lv.), and which Mr. McCarthy had performed successfully on a male adult 52 years of age. It consisted in opening the ileum. Both Trousseau and McCarthy have shown that this bowel will be reached in this region; an important fact as regards the nutrition of the patient. The great principle of practice upon which Mr. Maunder insisted was non-interference with the general contents of the abdomen. A knuckle of bowel having been exposed, that alone was to be manipulated. No particle of the intestinal contents must enter the peritoneal cavity; and, therefore, the utmost care must be had to plug the wound with the protruded bowel. It was noteworthy that gastro-enterotomy (artificial anus in the small intestine) was not even alluded to in some recent English works on Surgery, probably because it had been regarded as too dangerous to life, a sufficient distinction not having been drawn between the operation now under consideration and gastrotomy, in which search was made for the obstruction. In this search lay the danger. Another reason was the supposed uncertainty at what distance from the stomach the small intestine would be opened, and early death by inanition (erroneously) expected. In the present instance, the excreta were of a brown colour, and all but solid. In February, 1876, the patient had gained flesh; was in capital health, and went about as usual. With one exception, the author could learn by inquiries among professional brethren of no other instance of recovery in the history of British surgery. In two cases only had he recommended this operation, and in both it had been successfully performed.

Mr. Brown had seen the case within a few days, said the patient could walk four miles, and that he suffered no inconvenience from the wound; scarcely ever passing flatus. The patient injected warm water daily to relieve the bowels.

Mr. Smith referred to a case in which he had operated, but unsuccessfully.

ANEURISM OF THE ARCH OF THE AORTA, WITH OBSTRUCTION TO THE PASSAGE OF BLOOD THROUGH THE LEFT CAROTID AND SUBCLAVIAN ARTERIES; SPONTANEOUS CURE OF THE ANEURISM NEARLY COMPLETED; DEATH FROM EMPYEMA.

Dr. Greenhow read notes of the case which was that of a needlewoman, aged 45, married. Her father and mother had both died of phthisis. The patient had been subject to coughs and colds; and, for two years before coming under observation, had never been free from cough and shortness of breath. Three months before admission to the Middlesex Hospital, she had had rigors, followed by pain in the left side of the thorax. On admission to the hospital, her breathing was laboured; her respirations were 32; she lay constantly on the left side, and when placed on the right side, gasped for breath, and appeared to be dying. Her pulse was 130; her temperature 100·7 deg. The chest appeared larger on the left than on the right side, both in front and behind; and the left side did not expand at all during inspiration, whilst the integuments of the same side were œdematous. There was general dulness over the left lung on percussion, and absence of breathing-sounds throughout the same area, except at a small space below the spine of the left scapula. The respiratory sounds were mostly normal over the right lung. The heart was pushed to the right, and its impulse could be felt all over the left lung. Its sounds were normal. No pulse could be detected in the left subclavian, brachial, or radial artery. The pupils were equal; the voice was unchanged; and there was no difficulty in swallowing. The left arm was not swollen. There was frequent cough, and much muco-purulent sputum was raised. After a time, the left mamma became inflamed, and was incised; the patient died shortly afterwards. At the post-mortem examination, an abscess was found just beneath the left pectoralis major muscle, communicating with the pleural cavity through the third intercostal space. Three pints of pus were drawn from the left pleural sac; and the left lung lay at the back of the cavity, against the spine, bound down by firm adhesions. An aneurismal sac, adherent to the sternum and the left lung, was found at the upper part of the thorax. It sprang from the summit of the arch of the aorta, between the left subclavian and carotid arteries; measured eleven inches from right to left, and ten inches from front to back; communicated with the aorta by a very wide mouth; and was almost completely filled with laminated decolourised fibrine. The innominate artery was patent; an inch to its left was the left carotid, of which the channel was completely obliterated, the vessel itself for an inch lying in the wall of the aneurism. The left subclavian artery was distant three and three-quarter inches from the carotid; it lay partly in the aneurismal sac, and a bristle could be passed through it into the aorta. The aorta generally was atheromatous. Dr. Greenhow remarked that twice during life, when the empyema was known to exist, the chest was tapped, but that the trocar each time penetrated the left lung, and failed to draw off any fluid. At the same time an intra-thoracic tumour was diagnosed, which was at first believed to be cancerous, but afterwards aneurismal, there being no pulsation of the left radial artery. Dr. Greenhow thought it probable that, during life, no blood had latterly passed through the narrowed left subclavian artery, and that the impediment to the circulation through this vessel and the left carotid artery had favoured the deposit of laminated clot in the aneurism, with which eventually its cavity had been nearly filled. The case was important in its bearing upon the question of the surgical treatment of such aneurisms by ligature upon the distal side of the sac. Mr. Brasdor had proposed such an operation; and Mr. Heath, in 1872, exhibited a

patient whose left carotid artery he had tied for aneurism of the ascending portion and arch of the aorta, and who had been greatly benefited by the operation. Dr. Greenhow thought that the case which he had just related, and which showed spontaneous cure of the aneurism, almost completed, in connection with occlusion of the two distal vessels nearest to the sac, afforded strong corroborative support to this plan of treatment for the cure of thoracic aneurisms.

ANEURISM OF THE ARCH OF THE AORTA: LIGATURE OF THE LEFT CAROTID ARTERY: RELIEF TO THE SYMPTOMS, AND DIMINUTION OF THE TUMOUR.

Mr. HOLMES brought forward this case. The patient, a woman aged twenty-one, had never had any accident; but the present disease was attributed to an attack of rheumatic fever a year ago. When admitted into St. George's Hospital, she had a very large aneurism, occupying the terminal part of the aortic arch, with an exceedingly loud *bruit*, and a very strong thrill over the two upper intercostal spaces. The condition of the heart was difficult to judge of, on account of the loudness of the *bruit* and the pressure of the large tumour, which seemed to have displaced it downwards. No pulse could be felt in any of the arteries of the left arm. The pulse in the two carotids was natural, and in the right radial it was regular and about 60. She suffered occasionally from hæmoptysis, and was liable to faint at the least exertion. The treatment by complete rest and restricted diet (on Mr. Jolliffe Tufnell's plan) was carried out for several months, and with much benefit; and she improved so much after several months of this treatment, that in August, 1875, she was sent to the Convalescent Hospital at Wimbledon, where she was allowed to get up a little and to take ordinary diet; but she returned to St. George's Hospital in October with the pulsation and *bruit* somewhat increased. She was again put to bed; but as the aneurism appeared distinctly advancing up the left side of the neck, and there was considerable bronchitis, it was thought advisable to tie the left common carotid artery. It should be mentioned that in the interval since her first admission, the condition of the arteries of the left arm had varied much. Sometimes no pulse whatever could be felt; more commonly the pulse could be felt, though not very plainly, in the brachial artery, and more easily in the ulnar, while in the radial it was only occasionally perceptible. The operation (on October 21st) was followed by very great, but not immediate, benefit. It was not till the second day that any marked change was perceived, when the area and strength of the thrill began obviously to diminish, and continued to do so for a month—the first intercostal space, which had been bulged out by the tumour, becoming concave—and the symptoms of pressure on the air passages very much relieved. In this state she still continued. There was now (March 10th, 1876) a very loud *bruit*, but she was well enough to get up a little during the day, and had evidently derived very great benefit from the operation. In remarking on this case, Mr. Holmes observed that it was an incomplete one, and was only produced as an interesting pendant to that of Dr. Headlam Greenhow. In the latter case the left subclavian was obliterated; in the present there was some obstruction, the nature of which was rather hard to determine. It could not have been the result of pressure on the trunk artery, seeing that the brachial was pulsating while the radial could not be felt, nor the result of obstruction of the individual vessels by embolic clots; at least such obstruction could not be complete, for the pulse was felt at one time and not at another. But, on the whole, it testified to some obstruction to the growth of the tumour in the direction of the left subclavian, and encouraged the attempt to stop the growth of the aneurism up the neck and towards the trachea, by tying the left carotid; and the result had certainly, up to the present time, justified the operation. Mr. Holmes was inclined to attribute the benefit produced by the distal ligature in aneurism to the cessation of the circulation through that part of the sac with which the tied artery was in direct continuity. If this were so, the indications for the ligature of the carotid (left or right) in aortic aneurism, and of the right carotid in innominate aneurism, must be the growth of the tumour up the neck, and the advancing symptoms of pressure on the trachea; and such were the indications relied on in the present instance. If this view were correct, it would also follow that the ligature of the third part of the subclavian held out no such prospect of benefit, since the whole circulation must still go on through the branches of the first part of the subclavian; and it might even be apprehended that the rapid increase which must take place in the circulation through those branches might possibly be accompanied by an increase in the tension of the sac.

Dr. DOUGLAS POWELL thought it difficult to say when surgical interference should be resorted to. He had had a case under his care in the Brompton Hospital in which there was an aortic aneurism, where the left carotid and subclavian were given off. He had treated the case with complete rest and diet for five months without any marked benefit. He then consulted about the operation, but was glad it had not been performed, for now the patient was going about; great improvement had taken place. He might add that the left radial artery was pulseless; the pulsation over the tumour was much less.

Dr. BURNEY YEO asked Dr. Greenhow where he punctured in his case of thoracentesis; to which Dr. Greenhow replied that the first puncture was made at the back of the axilla, and the second one inch in front of the first. Had he punctured further forward, doubtless the fluid would have been reached, but he was deterred from so doing by the impulse of the heart in that region.

Mr. CHRISTOPHER HEATH had tied the carotid and subclavian artery with well marked decrease in all symptoms lasting over four years, and then followed by death from intemperance. The case in which he had tied the carotid only had also now lived four years. These cases proved the utility of surgical operations for aortic aneurisms. The difficulty was to say which artery ought to be tied—which artery was the next beyond the aneurism. It had happened to him to tie the wrong carotid, and the patient died from anæmia of the brain for the reason, that the aneurism obstructed the one carotid artery and the ligature obstructed the other so that no able, as it contains a comparison of recent information with blood could reach the brain. He was very disappointed at the assistance rendered by the sphygmograph, which he thought could not be relied on. As regards the question, when should the operation be performed? it could not be said definitely; it was one for experimental research, and if the treatment of the physician were useless, the case might be said to require surgical interference.

Dr. MAHOMED had never met with an aneurism on which the sphygmograph had not thrown some light. He could refer to cases which had not been suspected until the sphygmograph was used. One aneurism he had proved to be confined to the innominate artery, and not affecting the aorta, verified by post-mortem examination. In a case now under the care of Mr. Lane, he believed the sphygmograph had proved the presence of an arterio-venous aneurism, for the markings varied with respiration showing the inspiratory effort diminished the blood and decreased the pulsation.

Mr. HOLMES said that in the treatment of aortic aneurisms he considered ligature of the carotid to have a good effect, but he did not advise ligature of the subclavian in the third part of its course, because, as all the branches were given off in the first and second part of its course, the circulation through those vessels was increased, and the pressure of the blood in the main trunk increased proportionally. Under any circumstances the operation was serious, and its results doubtful, and should not be undertaken until the rest and diet treatment had been long and carefully tried.

Mr. HEATH said Mr. Holmes appeared to take it for granted that the exact position of the aneurism could always be defined; but such was not the case. It was in this particular point that the surgeon required the assistance of the physician; but physicians could not always decide. In one case of ligature of the carotid, the aneurism was on the right side, but he tied the left carotid and the operation was successful. In another case the aneurism was on the right, and he tied the left vessel, but he was wrong. The object was to tie the vessel next beyond the aneurism.

DUBLIN OBSTETRICAL SOCIETY.

THE fourth meeting of the session was held on Saturday, Feb. 12, the President of the Society, Dr. LOMBE ATTHILL, in the chair.

ASCARIS LUMBRICOIDES.

Surgeon-Major J. JOHNSTON exhibited under the microscope a specimen of the *ascaris lumbricoides*, which he found in very active motion in the os uteri, in a case of vesico-vaginal fistula.

The President said the specimen was a very interesting one. It had been found in a position in which it had never been seen before. If it had not been discovered it might have traversed the Fallopian tubes, and given rise to very distressing symptoms.

Dr. KIDD said they had read of the ascaris having crept out of the anus into the lower part of the vagina, but he thought it was a new fact to find that it had passed up so high as the os uteri; and he thought it was a fact that they were very much indebted to Dr. Johnston for having placed it on record. If it had succeeded in establishing a habitation there it would have created a considerable deal of inconvenience.

MYXOMATOUS TUMOUR.

Dr. F. T. PORTER exhibited a specimen of myxomatous tumour of the uterus, which he had obtained in the course of dissection.

UNDILATABLE OS UTERI.

The Hon. Secretary, Dr. J. R. KIRKPATRICK, for Dr. M'GUIRE, then read a paper on this subject.

The PRESIDENT thought it would be a dangerous principle to lay down that in all cases in which the os refused to dilate they were to use the forceps. He had, however, used the forceps in a case of undilatable os, and in some instances he had been gratified with the result.

Dr. CRONYN, who had seen a great many cases of unyielding os, had never seen the practice of incision of the os resorted to.

Dr. KIDD said he never used the forceps in any that could at all be called a case of undilatable os. There could be no worse practice than, with an os uteri an inch in diameter, hard and unyielding, to force delivery with the forceps. He thought by so doing the life of the patient was endangered. To introduce a hard iron instrument for the purpose of overcoming the rigidity of the os was a most injudicious practice.

Dr. DENHAM endorsed the views of Dr. Kidd. Nothing could, in his opinion, be more reprehensible than the idea of passing a forceps into an undilated or undilatable os.

Dr. GEORGE JOHNSTON thought it was most unjustifiable for any man to attempt to apply the forceps in the case of an undilatable os; but there was a difference between an undilated and an undilatable os. In many instances, by getting his fingers into the os, he could expand it a couple of inches wide, to introduce the forceps. He had had over 160 cases in which the forceps was used before the os was fully dilated, and there were only 10 deaths. He had only been obliged to perform incision of the os once, after he had adopted all the methods that they usually had recourse to to dilate it. He just incised the edge in one place, and he was then able to expand it. With that exception he never was obliged to perform the operation.

Dr. F. T. PORTER considered that a full dose of opium was almost as dangerous to the child as ergot was.

The PRESIDENT said he entirely disapproved of the principles laid down for general practice by the author of the paper. He (Dr. Atthill) was quite sure, if the practice of forcing delivery was carried out as a general practice, it would be most dangerous. He thought the exhibition of chloral in doses of 10 or 15 grains at intervals of 15 or 20 minutes until between 60 and 80 grains had been given was a better course of treatment than opium. He had been greatly surprised at the advantageous effect that a few drops of chloral had wrought in the few cases of rigid os he had met with.

Dr. T. MORE MADDEN said he had incised the os in more than one instance with very great advantage. He thought the practice of incising the os was a very useful one in some few cases in which the rigidity could not be otherwise overcome. He considered that the paper was the work of an able and practical thinker, though he (Dr. More Madden) entirely dissented from his practice.

ON THE USE OF THE SHORT STRAIGHT FORCEPS.

The discussion on Dr. T. More Madden's paper on "The Use of the Short Straight Forceps as a Tractor, and the Long Double-curve Forceps as a Lever and Compressor," was resumed.

Dr. CRONYN could not consider the forceps exhibited by Dr. T. More Madden as being in any degree an improvement upon the instruments in use. He (Dr. Cronyn) confessed that for a great many years—ever since he was Assistant Physician at the Rotundo Lying-in Hospital—he had been in the habit of using Beatty's forceps, and on only two occasions for years had he had recourse to the long forceps. He had never met with a case, with the exception of those two, which he could not deal with with Dr. Beatty's forceps. He had no hesitation in saying that he quite agreed in the theory that, as a rule, the forceps should only be used when the head of the child was in the cavity of the pelvis.

Dr. DENHAM thought the real question at issue was as to the time at which the forceps should be used. He was satisfied that a great deal of mortality had occurred from waiting too long. He thought no injury whatever arose to the patient from waiting until the first stage of labour was completed. He thought the experience of practitioners was that, as a rule, there was little apprehension of danger to mother or child until the os was dilated. He believed that in ninety-nine cases out of a hundred they might wait until the os was fully dilated. The subject was one of very deep importance. He had very little faith in the double-curved forceps.

Dr. GEORGE JOHNSTON said the deaths in the Rotundo Hospital in cases where the forceps had been applied before the os was fully dilated was one in sixteen. He was perfectly convinced that he saved the lives of both mother and child where he had applied the forceps in these cases. The only reason that he preferred Barnes' instrument was because it was lighter than the others, and had all the advantages that might be required.

Dr. T. MORE MADDEN said—As upwards of six months have elapsed since the paper now under discussion was read here, at the closing meeting of our last session, I may perhaps be permitted to remind the Society that its subject was the "History and Use of the Short Straight Forceps as a Tractor, and of the Long Double-curved Forceps as a Lever and Compressor," and that being designed for a twofold purpose, it was divided into two parts, only one of which has been alluded to during the protracted discussion which has since ensued. In the first part I entered very fully into the history of the forceps, for the purpose of showing that the very early and very frequent recourse to this instrument now recommended by some is but the revival of a practice introduced into vogue by the earliest authorities on operative midwifery, and I quoted passages from the work of Giffard, Chapman, Ould, Smellie, and several others of the first writers who described the forceps, to prove that shortly after its introduction the evils resulting from the premature employment and injudicious application of the forceps in the hands of the ignorant and unscrupulous men-midwives of the 17th and down to the latter part of the 18th century led to a reaction against even the legitimate use of this noble instrument, extending even to those cases in which its use was absolutely necessary for the safety of the parturient woman and of the child, and from the evil effects of which the practice of midwifery has been only very recently emancipated. In the second part of my paper I described two instruments, which I exhibited, and which I considered to be improvements on the ordinary straight and double-curved forceps, and I gave a detailed account of my use of the instruments in a very large number of cases, and made some observations as to the mannar in which they should be used, and the circumstances under which they should be resorted to. This paper, which was read last July, has now been very fully discussed and very freely criticised at three meetings of the Society. I should be quite satisfied with having thus attracted the attention of the Society to a subject of great practical importance, and would not now occupy your time were it not that I think some of the eminent obstetricians who do not agree with my views have hardly done them justice. Dr. Byrne has found fault with my use of the forceps in cases of threatened rupture of the uterus, and says that there are no symptoms which would warrant us in pronouncing that this accident was likely to occur in any particular case. I, however, was always under the impression that these premonitory symptoms of rupture were familiar as household words. I always endeavoured to impress them on the minds of students, and as an examiner I should unhesitatingly have rejected any candidate for his degree at the Queen's University or for the diploma of the Rotundo who was not acquainted with the signs which should warn him that this fearful accident was impending, and was not prepared to take the proper steps to avert it, as was done in the case I detailed in my paper. Dr. Byrne endeavours to prove that the mortality in my forceps cases was very high. Now I think this charge is hardly borne out by the facts of the case. Thus the tables I read here contain an account of 163 cases in which I applied the forceps in the hospital and in private and consultation practice, and of these many were cases of a most unfavourable kind, including rupture of the uterus, convulsions, exhaustion, and hæmorrhage, where I was only called in to deliver a woman who must inevitably have died unless delivered artificially. Now out of all these cases how many died? Only eleven; and of these, one, four weeks after delivery, from typhoid fever, and the ther nine days after delivery, from secondary

hæmorrhage. The former case should be excluded from this table, as the woman died four weeks after delivery from a non-puerperal disease. There were therefore but ten deaths in my 1163 forceps cases, and of these one was moribund from rupture of the uterus, two were dying of convulsions at the moment they were delivered, and a considerable proportion of the others died from epidemic disease. So that I believe the result of my forceps cases will bear a comparison with that of any practitioner who records his cases as honestly and as accurately, whether they be favourable or not, as I have done. Dr. Johnston, without entering into any reasons, characterises my short forceps as a weak instrument; but though the long forceps which he prefers is undoubtedly in his hand quite as safe as any instrument could be, still I have more than once seen reason to regret that, employed as they now are, before the os uteri is fully dilated, it would be well that young practitioners at least could be restricted to the use of a short forceps like mine, equally useful, and incomparably less hazardous than the long forceps are in incompetent or unskilled hands, and I cannot refrain from again thinking that it is more necessary to restrain than to stimulate the operative ardour of the pupils of a great school of midwifery, and to impress on them the paramount necessity of caution, prudence, and great patience in the management of labours, rather than the acquirement of mere operative dexterity. The President, Dr. Atthill, has very clearly surveyed the points which I was anxious to bring under the consideration of the Society. But the instruments he has exhibited from the museum of the hospital are entirely different in form and curvature, in the annexed screw, and in fact, in almost every respect from those I showed here last night, except that, like mine, one was a long and the other a short forceps. I should be very glad if Dr. Atthill would give my short forceps a trial in the hospital over which he presides, as if he did so he would, like other practitioners, come to use no other instrument in the second stage of labour. With regard to Dr. Porter's question, I have not myself noticed any ill effects to the children delivered by the forceps, but I can well conceive it quite possible that sad effects might be produced by the great pressure of my long double-curved forceps. Dr. Kidd has, I am glad to say, sustained my opinion that the long forceps should not be applied as a rule of practice before the full dilatation of the os uteri, and without admitting it, both Dr. Kidd and Dr. M'Clintock bear out my view that two different forceps should be employed, as they draw a clear distinction between the operation which they call the high operation, before the head has passed through the brim, and in which I said a long forceps was required, and what they call the middle and low operation, in which the head is in the cavity of the pelvis, or on the perinæum, and in which delivery might be effected with my short forceps. I only regret that the lateness of the hour does not permit my replying as I had intended, and hoped to do to the other speakers who have done me the honour to take part in this discussion.

The Society then adjourned.

Apropos of our remarks last week on the abolition of militia surgeoncies, a narrative of the effect of such a movement may be interesting. A certain regiment in the north of England recently mustered for training. The officers assembled and accosted each other, but no doctor amongst them, the regimental depôt surgeon being stationed thirty miles off, busy with his proper duty. Next morning the recruits assemble for examination, with sergeants in charge, and the officers whistling away the time until the doctor arrives to pass them. The day advances and the telegraph is set to work, but fails, after an expenditure of many shillings, much patience, and an abundance of expletives, in producing the medical officer. Meanwhile no one knows what to do with the recruits, who, not being soldiers, can neither be armed, billeted, or paid, and are still loafing about waiting to pass the medical examination, for which no doctor is forthcoming. Finally, there is a consultation of officers, who decide to call in the services of the nearest civil practitioner, who attends with his assistant late in the evening, and in about two hours earns a large sum by passing the recruits. Next day comes the arrival of the long-expected doctor, after the work is done, and the next week a tornado at the War Office, in consequence of the expenditure.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, MARCH 29, 1876.

THE BILLS FOR THE AMENDMENT OF THE MEDICAL ACT.

We understand that the Colleges of Physicians and Surgeons have presented petitions to Parliament against Mr. Cowper-Temple's Bill for the admission of women educated in foreign universities to the privileges of registration as medical practitioners. The ground on which these petitions are based is not at all conversant with the question whether women should or should not be allowed entrance to the profession, on which question the College of Physicians has to a certain extent expressed itself affirmatively. Mr. Cowper-Temple's Bill proposes to open to women portals which the law and the Medical Council have rigidly closed against men, and it proposes to recognise as qualifications to practise medicine in these kingdoms degrees of the sufficiency of which as guarantees of education we have neither knowledge nor control. If a home licensing body establishes a new degree, it must satisfy the Medical Council that the course of study and the examination are up to the required standard, and even then it will not confer a right to practise until it is placed on the Register by a special Act of Parliament; and, if the licensing body should at any time unduly lower the standard of the degree, the Medical Council has power to disfranchise ir by representing the matter to the Privy Council. In the case of the foreign universities, we do not know that the curriculum or examination is sufficient; and if the degrees were once admitted to the Register, we have no right of visitation and inspection which would satisfy us that the educational level of those degrees was kept up.

We opine that the Bill is not likely to pass. It is not in any case to have its second reading until July, and we believe the President of the Medical Council has already warned the Government as to the measure. It is in principle the same as that against which last year the Medical Council, through the executive committee, entered a strong protest.

Mr. Gibson's Bill also deals with the recognition or registration of new degrees, for its third clause proposes to place upon the Register the Baccalaureate in Surgery and the State Medicine Diploma of Dublin University.

We argued last week that this latter degree, not being in any respect recognisable as a medical or surgical qualification, was not entitled to registration except as a qualification additional to other degrees. Since we called attention to the subject, we understand that the Branch Medical Council for Ireland has had a meeting thereupon, and has resolved unanimously—in reference to Clause 3—that it "requires very serious consideration, and that a bill containing that clause should not be pressed forward without affording to the General Medical Council and the medical corporations of the United Kingdom represented on it time for considering the effects of that clause."

This Bill is set down for the 30th of March for second reading, and as its chances of passing are good, we trust that the President of the Medical Council will have lodged a *caveat* against this clause before it is too late.

THE ROTUNDA HOSPITAL.

Few of our readers are unacquainted with the splendid range of buildings, commonly known as the Rotunda Hospital, which constitute so noble a monument of one man's philanthropy, that man, too, being a member of our profession.

More than a hundred years ago, Dr. Bartholomew Mosse conceived the idea of rearing an hospital which would be at once a refuge for poor suffering women, and a great school of midwifery. With untiring energy he carried out his great plan, and though he himself died in poverty, his memory has ever been revered as one of the greatest benefactors of his fellow-creatures and of his country.

Nor was he content with erecting a magnificent hospital; he sought also to place it on a sure foundation by creating an income for its future support; but his efforts in this respect only serve as another proof of the fallacy of man's foresight. His provision for the future maintenance of the hospital, which he expected would be permanent, was to be derived mainly from four sources—

1st. A tax imposed by Act of Parliament on "public sedan chairs."
2nd. A Government grant of £3,000 a year.
3rd. The profits derived from entertainments given in the Rotunda and adjoining ground.
4th. A tax imposed on the inhabitants of the square, in consideration of which the governors were bound to light it.

As to the first, "public sedan chairs" being things of the past, the tax no longer exists as a source of income; but, unfortunately, a sum of £11,000 was borrowed, chargeable on this tax, and the interest, amounting to £440 a year, has still to be paid by the hospital, although the "chair-tax" is gone.

Next, our paternal Government has slowly but surely withdrawn its aid; the £3,000 a year has been reduced to £700, and this pittance is continued solely on the ground of the great national benefit conferred by the hospital as an ducational establishment.

Third. The profits derived from the public rooms and gardens, at one time very large, and even in our own student days estimated at £1,000 a year, now realise but £300. This falling off has been specially marked since the opening of the Exhibition Palace.

Fourth. The square tax, too, has ceased to produce a revenue. A clever lawyer having raised the point that the lighting should be by oil lamps, not by gas, the question is still *sub judice;* so we can only say that for the present the charity loses this source of income.

To sum up our comments, this excellent charity, this renowned school of midwifery, which for a hundred years has attracted pupils from all parts of the world, which has furnished a succession of obstetricians who have rendered the Dublin School of Midwifery famous, has gradually had its sources of income dried up, and that, too, from no fault in itself, or on the part of its managers. The result is easy to anticipate. The institution is this day in debt to an extent not much under £1,000. Nor is this all. It is an old building; time has told on its fabric; it needs extensive repairs, especially the chronic wards, those devoted to the treatment of the "diseases peculiar to women." They urgently need repair. In fact, nearly £2,000 must be promptly expended on this wing, or these wards must be closed.

Can any Irishman read this brief outline of the history of this renowned hospital without feeling a wish to aid it? We call on the members of our profession to remember how much they owe to it. Let its old *alumni*, the hundreds of "old Rotunda pupils" throughout the kingdom, come forward with their contributions, be they ever so small; still more, let them, among their patients and acquaintances, urge its claims. They are those of no common nature. They are those of a charity and of a school of midwifery of which Ireland is justly proud. As a charity it annualy relieves some thousands of the suffering poor, while to the wealthy classes its existence is no less valuable, since from the experience obtained within its walls the wives and daughters of the rich derive the greatest benefit. Let physicians, then, impress these facts on their patients and acquaintances, and the difficulties into which this great institution has fallen will soon be removed.

Contributions should be remitted to the Master or Secretary at the Hospital, and all such will be acknowledged in our columns.

THE MEETING OF THE GENERAL MEDICAL COUNCIL.

The Executive Committee, which met last week has, we understand, adjourned, with the intention that the Council shall hold its usual annual meeting in the end of May, a decision which we hope the President will not allow to influence him. We have never understood the reasons which have caused the annual assemblies of the Council to be put off until the hour had passed for doing anything except talk of exploded questions. Year after year the profession is agitated—as it is at the present moment—by attempts at legislation upon which the Medical Council should have a consultation and a well-considered opinion, and, year after year, these questions settle themselves, or are settled by the individual interference of the President, the Council as a whol ebeing profoundly ignorant and absolutely silent upon them. Not until close upon the dog days, when medical men, Members of Parliament and ministers are all hopelessly *blasé* does the Medical Council come together to consider

subjects which have been debated in the mind of the profession months before. If the Council is never again to initiate any action for the good of the profession or the public, it might at least interest itself in considering the action initiated by others, and we venture to observe that the profession expects something from it more than a pleasant summer trip to the metropolis and a dull chat over subjects which have little interest in comparison to those which have been settled beforehand. If the Council were what it might be, it would be up and doing at the opening of Parliament each February. If its meeting for 1876 be held at the end of May it might—for legislative purposes—be as well not held at all.

A JUST CONVICTION.

A FARMER named Henry Bayfield Hatch, of Cannon Court Farm, near Leatherhead, was summoned before Mr. Benson, at the Southwark Police Court, under the Sale of Food and Drugs Act, 38 and 39 Vic., cap. 63, sec. 6, for selling to Henry Kirby, at the Waterloo Railway Terminus, "milk which was not of the nature, substance and quality of the article demanded by such purchaser." The nominal complainant in the case was a wholesale dealer in milk, who was in the habit of receiving 2,000 gallons of milk daily at the Waterloo Terminus, from farmers in the country, which he sold to the retailers. In the early part of last month he arranged with the defendant for a daily supply at that station, and shortly afterwards he received complaints from the retailers which induced him to communicate with Mr. Coxhead, one of the sanitary inspectors, who took samples of the milk and forwarded one of the sealed bottles to Dr. Muter for analysis. The certificate of that gentleman showed that the milk was adulterated to the extent of 20 per cent. with water. The magistrate was reminded that many retail dealers had been fined heavily for selling adulterated milk, entailing great hardship upon those poor men, owing to the acts of the farmers who supplied the wholesale dealers.

A conviction was obtained, and the defendant was fined and had to pay the costs

We recommend this case to the consideration of sanitary officers; let them go at once to the fountain-head, examine the article in bulk as well as in retail, and they will probably discover culprits for whose individual sins dozens of retailers may have to suffer.

It may appear somewhat hard upon the retailer that he should be answerable for the guilt of another, but the public must hold the retailer responsible for the purity of the article which he sells. It is for him to see that he purchases what he undertakes to sell. When the retailer of milk enters into a contract with a farmer to supply him with so many gallons *per diem*, that contract is in itself a warranty that the unadulterated article shall be supplied; and if there can be any doubt as to its purity, surely it becomes the retailer's duty to have the article tested in bulk, as in the case above reported, and not to allow the fraud to be carried on until accidentalty discovered by one of his customers who may happen to be more discerning than the greater portion of the public.

We never have been able to recognise the grounds upon which the grocer, druggist, or milkman claim to be treated differently from every other tradesman who is held responsible for the good quality of his wares. If an ironmonger sold an article as wrought iron and it turned out to be cast metal, would he be allowed to plead that he did not know the difference himself, or to refer the complaining consumer to the maker who sold the article to him? If a jeweller sells a ring as gold, and it proves on service to be only plated, would he be permitted to say that he was told it was gold—did not know how to find out whether it was or not—and did not consider himself at all liable for the little mistake? If not, why should a druggist be allowed to sell mustard two-thirds flour and turmeric, or senna one-half false leaves, and then protest that it was a great hardship on him that he should be prosecuted for doing so? Let him do as any other tradesman does. If he is unable to answer for the quality of the article from his own observation, let him give the manufacturer an explicit written order for the exact article which he requires, and if anything else be supplied, he has his remedy at all times against the manufacturer for any penalty which he may suffer. Inconsistent as the statement may appear, we have no objection at all to admixtures so long as they are honest and not poisonous. We can quite believe that mustard and flour, or cocoa and starch, may be more palatable, and at the same time cheaper than genuine mustard or cocoa. We believe also that if these articles were honestly sold as mustard or cocoa mixture, and the composition made known and sold, as they might be, at a much lower price than the genuine article, they would be found by the public to serve their purpose, and would be bought largely without the inducement of any misrepresentation.

Notes on Current Topics.

On Absorption by the Human Diaphragm.

DR. ARCADIUS RAJEWSKY, of St. Petersburg, has made experiments with the human diaphragm, by which he obtained the following results:—

1. The normal diaphragm absorbs fluids and such substances as there are dissolved in these.

2. if the diaphragm be inflamed, it allows fluids coming into contact with it to pass its system of vessels more easily.

3. When an inflamed diaphragm becomes injected, it will be seen that the intercellular spaces are connected with the lymphatic capillaries, and that they form peculiar canaliculi in the connective tissue.

4. After the removal of the epithelium of the serous membrane, there are opened new avenues for the transportation of fluids, by the intercellular canaliculi commencing on the surface of the membrane.

Singular Vital Statistics.

THE *Philadelphia Medical Reporter* says it is wonderful how large is the increase of wounded soldiers each year since the American war, according to the Pension Office rolls. Not less marvellous is the extraordinary longevity of the survivors of the war of 1812. That was not agrea

war; not many troops were engaged, and no very large force mustered into the service of the United States, and the war came to an end almost sixty-one years ago. Yet the Commissioner of Pensions reports 15,875 survivors of that war on the rolls of the pensions. Very few, indeed, of these can be less than eighty years of age, and the number must be nearly if not quite ten per cent. of the whole force mustered for service. If the veterans of the late war of the rebellion prove so tenacious of life, nearly 200,000 of them will survive in the year 1926.

Hospital Saturday in Birmingham.

SATURDAY last was "Hospital Saturday" in Birmingham. Contributions from the various works were paid in at the Joint Stock Bank, and amounted to between £1,100 and £1,200. The Licensed Victuallers' lists did not close till late at night; other contributions will no doubt be received. The collections last year amounted to £3,800, but a considerable falling off is anticipated this year on account of depression in trade.

A Puzzle for the Doctors.

THE *Globe*, under the title of "A Puzzle for the Doctors," refers to a case described in the New York papers. The subject of the attack was a well-to-do farmer, taken suddenly with convulsions. These convulsions were said to be terrible to witness, and to make their attack every year. He experienced no pain during the attack, but was conscious the whole time, though unable to prevent it. His contortions were described as simply horrible, every muscle in the body writhing and twisting.

The people supposed the man to be possessed of the devil.

Receiving this report from New York papers, it is difficult to know how much is true and how much untrue, especially as there is a clear and descriptive account of the patient "assuming all manner of shapes and actually tying himself in a knot." If the patient had not "actually tied himself in a knot," we might look upon the case as no great puzzle for the doctors. Certain diseased conditions of the cerebellum, including tumours, sometimes produce convulsions most painful to witness, but yet the patient feels no pain, and, though perfectly conscious of what is going on, he is unable to overcome his movements. The diseased conditions to which we refer are not accompanied by an attack of periodical occurrence once a year, as in the case reported in the New York papers; but doubtless, if there is any truth in the reported symptoms there are physicians who could explain them.

The General Medical Council.

SOME important changes are about to take place in the General Medical Council. By the melancholy deaths of Drs. Parkes and Begbie, two seats are at the disposal of the Crown, and we understand that Dr. Sharpey, whom the Government were anxious to re-appoint, his term of office having just expired, has declined the honour, on the ground of failing sight and hearing. Thus the Government have the unusual number of three out of the six Crown nominations to fill before the next general meeting. We believe we are correct in stating that Professor Lister, of Edinburgh, will replace Dr. Begbie, and it is the general wish that the remaining vacancies shall be filled by the two most fitting representatives of the profession in the English provinces. On whomsoever the choice may fall, we trust that the claims of surgery will not be overlooked: medicine has already too great a preponderance in the Council. Another important change will, we hear, occur at the next meeting. Dr. Francis Hawkins has sent in his resignation as General Registrar, and a successor will have to be chosen. Hitherto this office has not debarred its holder from private practice, but this will not be the case in future. The duties are quite sufficient to occupy the entire attention of a registrar, and we understand this will be a *sine quâ non* in the new appointment.

Japanese Jugglery.

THE Japanese are a wonderful race; the facility with which they accommodate themselves to circumstances is surprising. Their powers of imitation are more than a match for their inventive genius, and as they find the former pay so much better of the two, we gradually see them dropping from their old pinnacle of original handicraft to one of servile imitation. It has been remarked that imitation is the sincerest form of flattery; but when it exists on the outer surface, and the inner is found like the whited sepulchres of Scripture, "full of dead men's bones," it becomes both repulsive and dangerous. These last three words express exactly what is going on in Japan at the present time in regard to the best known and appreciated articles of consumption, and medicines. If you desire a bottle of Bass, Allsopp, or Guinness, you get a facsimile bottle and label, but the contents is a vile concoction of native liquid of a very filthy nature. Dinneford's fluid magnesia, Dr. Collis Brown's chlorodyne, and many similar articles, come in for an equal share of native attention, the English Government stamp being copied with such exactitude as to deceive "the very elect" revenue officers. Yet there is no secret in the matter. From a friend just returned from Japan we learn that establishments exist in Yedo and Yokohama for the imitation of any label you like to take them, under the eyes of the Japanese Government; doubtless you could get a Bank of England note engraved with equal facility. The Japanese know that deception is being practised; but as the majority have never tasted the originals, they are unable to discriminate, and so content themselves by accepting what is palmed upon them as English, and to which their palates have become accustomed. Even Leibigs extract of meat label has been imitated and placed upon tins containing decomposed desiccated stuff, and sold at the highest figure in consequence of its ripeness. Surely the British Government can use some influence with the Japanese authorities to stop this traffic. The loss to the revenue of stamp duty should be one incentive for prompt remonstrance; the serious interference with the commerce of this country another; and the risk of selling articles dangerous both to health and life under colourable imitations of the English Government stamp the most potent of all. The subject is worthy of their consideration.

Surgeon-General Gordon, M.D., C.B.

We heartily congratulate Surgeon-General Gordon, who has been gazetted Honorary Physician to her Majesty the Queen. Dr. Gordon is a Commander of the Bath and of the Legion of Honour, and an author of considerable repute; his last work, entitled "Practical Hygiene and Surgery of the Franco-Prussian War," has laid army medical officer sunder real obligation; and we understand he has at present in the press a work on "Burmah and the Burmese," written during a journey through that country, of which so little is known, with the Commander-in-Chief of our Indian Forces, Dr. Gordon being at the time and still Surgeon-General of those forces. Much interest has been excited in literary circles about his forthcoming work, which, besides being of a popular nature, will contain chapters of interest to medical readers on the botany, zoology, climate, and medicines of the country, illustrated with photographs and sketches taken on the spot.

Official Revelations of Adulteration.

We have, as our readers know, entered with some warmth into the crusade against the rascalities of adulterators, and have done our best to counteract the overwhelming influences which the shop-keeping classes are enabled to exercise in Parliament, and by which they have been enabled to pass Mr. Sclater-Booth's Act of last year for the protection of trade frauds. The *Pharmaceutical Journal* and other trade periodicals have endeavoured to show that our statements as to the extent and importance of these trade rogueries were at the least exaggerated, being based, for the most part, on police-court prosecutions, in which the evidence might be open to doubt.

The Report of the Principal of the Somerset House Laboratory, which appears in the Eighteenth Report of the Commissioners of Ireland Revenue, recently presented to Parliament, supplies us with official evidence, which is not open to denial, or capable of being explained away. We select from it a few statements having special reference to articles in which the medical profession is interested:

"Last year," says the Principal, "there was a great scarcity of lemon juice sufficiently good in quality for ships' stores, and during the present year large quantities of foreign-squeezed juice have been presented for examination, but a considerable proportion had to be rejected, on account of its having been below the standard. The English squeezers of lemons are now so well aware that only good juice will be accepted that they seldom present inferior or diluted juice for examination, but foreign-squeezed juice is obviously prepared with little care, as it frequently contains common salts, and is sometimes diluted with water. During the past year only 12·6 per cent. of home-squeezed juice presented for examination had to be rejected, while 22·8 per cent. of foreign juice was declined.

"Although the quantity of juice rejected amounted to 23,325 gallons, no member of the trade has questioned the justness of a decision.

"Of the medicines used largely in tropical climates, which, on account of the difficulty of procuring them abroad, should be of the best description, and of the greatest purity, cinchona bark has been supplied of very inferior quality, being almost useless as a medicine, and, *in one or two instances, the bark examined was not cinchona bark at all.* Of the cinchona alkaloids supplied, some of the most expensive have been adulterated with those of little commercial or medicinal value, and, in several cases, one kind has been substituted for another, the substituted article being invariably of less value than the one it was made to represent.

"Ninety-two samples, consisting of beer and wine for hospital use and ships' stores, have been examined for the Admiralty. A beer sample taken from the supply was found to be 30 per cent. lower in commercial value than the tendered sample.

"One hundred and seventy-three samples of coffee, or substitutes for coffee, have been examined, and of this number 164 were adulterated. The proportion of adulterated samples is greatly in excess of the previous years, on account of a large seizure of roasted acorns having been made at a manufactory in the East End of London; the samples taken contained about 10 per cent. of coffee, the remainder being roasted acorns. Roasted acorns were first placed before the public as 'Pelotas coffee,' but the manufacture being illegal, it was prohibited. They were next introduced to the public under the name of 'Coffee Surrogate,' but the manufacture of this has also been stopped, and it is hoped that the seizure and condemnation of the article will be sufficient to deter the firm from again embarking in the trade.

"Fifty-nine samples of beer, and of substances used in the brewing of beer, have been examined. 31 were found to be genuine and 28 adulterated, the adulterants being common salt, liquorice, treacle, caramel, ginger, and, in one instance, tobacco.

"As many statements have been made in public that cocculus indicus is generally used as a beer adulterant, it has been considered advisable that during the past year close attention should be given to the subject. Officers and supervisors of intelligence regularly survey the brewers, and not one of them has been able to detect cocculus indicus on a brewer's premises, nor have the samples of beer examined here for many years past contained it. The reports which have, from time to time, been published of cocculus indicus being used as a beer adulterant have not proved satisfactory when thoroughly investigated, but much stress has been laid on the fact that a large quantity of the drug is imported into this country, and that, therefore, it must be used in the way stated. To solve this difficulty, careful inquiries have been made as to what becomes of the cocculus indicus imported, and it has been found that almost the whole of it is again exported, chiefly to Germany, and what is retained for home consumption is, according to returns obtained from wholesale chemists and drug grinders of undoubted respectability, used either for poisoning fish, or, when powdered and mixed with fat, employed as an ointment for killing lice on cattle."

Regarding the general question of adulteration in the light of this report, it must be borne in mind that the statements made therein refer to a very few out of the multitude of articles of daily consumption which are usually suspected to be adulterated. The Somerset House Laboratory is charged with the examination only of articles which pay duty or in which the Government is interested. When it is remembered that the manufacturers of such articles are aware that they will be liable to analysis, and, nevertheless, are in the habit of "trying on" these frauds, it may be easily imagined what is the condition of purity of articles which are put into circulation without any check upon their impurity except an occasional prosecution which Mr. Sclater-Booth and the shopkeepers have done their best to make abortive.

London Gas.

In one of the experiments explained in our report of Mr. Crookes' lecture at the Royal Institution he demonstrated that the force exerted by the light of a gas flame was five and a-half times greater than that of a candle, against whose effect it was balanced. There can be no

doubt that the chief part of the force in the case of the gas light was due to what he termed "the dark heat," that is, the heat of the extra red end of the spectrum. The interposition of blue glass reduces the force exerted by the light nearly one-half, and most London gas burns usually so blue that it might be mistaken for burning brimstone, or burning with a blue glass screen before it. Mr. Crookes should be requested to devote his attention to the examination of the London gas every week with the aid of his radiometer, as Professor Frankland tests the water of the various water companies, and so at least we might be in a position to read and write by night in London without the risk of headache and loss of sight from the great impurity of the gas.

A Vivisection Deputation.

A DEPUTATION headed by Lord Shaftesbury, Mr. Cowper-Temple, and others professing to represent a "Society for the Protection of Animals liable to Vivisection," waited on the Home Secretary last Monday to urge the immediate preparation of a measure of a restrictive character. It was evident, however, that some of the speakers did not understand the Report of the Royal Commissioners—probably had not read it—as one speaker said the report contained no recommendation as to the use of anæsthetics in experiments. Then it appeared by what others said, that the Society for the Protection of Animals had not made up its mind on other points, as some asked for total prohibition "for a system which was abominable and atrocious;" another for prohibition, because the progress of true physiological science will be promoted rather than retarded by the revolting cruelties which are sometimes practised in its name." When asked to point out the cruelties to which allusion had been made they could not do so. The climax was reached when one of the speakers told the Minister that "they (the deputation, we suppose) were divided as to the use of Royal Commissions, some believing that they were appointed merely to allow Parliament to evade troublesome questions," and so forth. This was too much, and elicited from Mr. Cross a warm disclaimer of any "shelving" propensities on his own part or that of the Government: "The report," he went on to say, "has only been a short time before the public, and I do not think you have any right to complain of delay. All I can say is that it has been and is now receiving very anxious and careful consideration. Although every one in the room is anxious that legistation should take place, and all speak of the report as very temperate, still the observations which have fallen from many hon. gentlemen present have tended to legislation in a very different direction to the report, quite sufficient to show what I am well aware is the extreme difficulty of any legislation—viz., to lead to general approval. It would be an extremely difficult matter to legislate upon when there are conflicting views of the question, and the only endeavour which the Government must make, and which they desire to make, is to come to a satisfactory conclusion on the whole."

The Anti-Vivisection Publications.

MR. DARWIN, in a letter to *Nature*, protests against the misrepresentations and garbled quotations put forth by the Society for the Protection of Animals liable to Vivisection on the Report of the Royal Commission on Vivisection. Under the heading of "Extracts of Evidence on Extension of the Practice of Vivisection, and Abuses connected therewith," the following words occur:—"Dr. Crichton Brown, describes 'forty-six animals sacrificed in trying if chloral were antagonistic to pycrotoxine. Cases of poisoning by pycrotoxine are of rare occurrence. Twenty-nine animals used in Ferrier's series.'"

"I will leave your readers to judge," writes Mr. Darwin, "of the kind of impression which this passage tends to give; I will only ask, is it in accordance with the ordinary principles of justice that the following important details (also gathered from Dr. Crichton Browne's evidence) should be entirely omitted by the compilers of the statement?

"1. Pycrotoxine is sold in large quantities as Barber's poisoned wheat for the destruction of birds (3218) concealed in an edible substance; this poison must therefore pass largely through the hands of an ignorant and careless class of persons.

"2. Dr. Crichton Browne succeeded in proving that, after a poisonous dose of pycrotoxine has been given to an animal, if a dose of chloral be given subsequently, the animal will recover (3163).

"3. The operation to which the animals sacrificed were subjected, 'consisted in the introduction under the skin of a little fluid, by means of a perforated needle . . the pain is infinitesimal (3218).

"4. The after effects are convulsions and death, and convulsions themselves are not necessarily painful (3218). This is proved by direct and distinct evidence.

"5. In consequence of the use made of Barber's poisoned wheat, numbers of small animals die of it in convulsions every year" (3218).

It is almost incredible that experiments which may result in saving human life should be mentioned in the manner above quoted; while a course of action, identical as far as the ultimate effect on the animal is concerned, in which there is no question of saving life, and which is repeated a thousand times for the private benefit of its performers, is omitted!

"6. In Dr. Ferrier's researches, anæsthetics were so 'carefully and liberally given' that five animals out of the twenty-nine sacrificed 'died before they were touched or operated on in any way.'" (3178).

Comment upon the doings of these professed societies for "The Protection of Animals," which must act at the expense of our common humanity, is quite unnecessary.

Deaths by Violence.

NONE but those accustomed to London life by night and day, can imagine the risks attending locomotion in its streets. The Registrar-General has supplied us with statistics of deaths from violence during the past year, which amounted to the enormous number of 2,852, or more by 82 than in 1874. Of these 298 were from suicide, and represent about the average number; they were much less frequent in October, November, and December than in the first three months of the year. The chief increase was in the deaths from negligence and accident. Accidental deaths by poisons were below, by drowning above, the average. The deaths by suffocation have recently shown a remarkable increase;

the annual numbers were on an average 407 during the six years 1865-70; in the last four years the numbers were 496, 534, 540, and 555. This increase deserves the attention of the coroners; nearly all the victims were children.

Two hundred and thirty-one men, women, and children, died of injuries by horses and vehicles in the street of London. It is the highest number yet recorded in a year. The vans, waggons, and drays killed 82, carts killed 55, cabs 39, omnibuses 18, carriages 15, horses 11. Tram-cars are driven now with more care than they were; the deaths they caused in the last three years declined from 17 to 14, and to 9. The vans, waggons, and carts are evidently not driven so skilfully as the other vehicles, and they have no sufficient breaks. Some of the victims were probably infirm and a few might have been intoxicated; but this was not the case with the majority. The *numbers injured* reported to the police, exclusive of 93 killed on the spot, were 2,926. So in this battle of the streets going on daily 231 were killed and more than 2,926 were wounded. Can nothing more be done to diminish these injuries and deaths?

The Metropolitan Water Supply.

Dr Frankland reports that the water supplied to the metropolis from the Thames in February was much less polluted by organic matter than that delivered in the previous month. We notice also that he ably combats the erroneous views entertained by Mr. John Evans, of the Geological Society, who tries to show, from the results of chemical analysis, that the polluted water of the Thames is purer than the spring water from the chalk, and thus seeks to make the inhabitants of the metropolis content with their present supply. Dr. Frankland says:—"His statements on this subject are founded upon an entire misconception of the meaning of the analytical results. A most exhaustive chemical examination of the river waters of the Thames basin, on the one hand, and of the spring and deep well waters on the other, has shown in the most unmistakable manner the immense superiority of the latter for dietetic purposes. Indeed, it is obvious that, even with the most efficient river conservancy imaginable, aided by the best efforts of the Legislature, the Thames must always receive so much pollution as to render its use for the supply of the metropolis highly objectionable. No preventive measures can hinder the washings of highly-manured land, the excrements of cattle, the imperfectly purified sewage of towns and villages, and the partially-cleansed discharges from paper mills, skinneries, and tan-yards from mingling with the stream in enormous quantities, and which, from a sanitary point of view, are of a highly dangerous character."

Cruelty of a Surgeon to an Imbecile Sister.

On Saturday, George Wyer, surgeon, of Eastwood, was sentenced to three months' imprisonment by Baron Huddleston, at the Nottingham Assizes, for cruelty to his imbecile sister, who has been in his care. From information which reached them, the Lunacy Commissioners sent a physician to Wyer's house, and in an attic he found the woman wallowing in dirt. She had neither clothes, fire, furniture, light, nor ventilation, the chimney being stuffed and the windows boarded. Only a streak of light was visible through a nick. A neighbour stated that she often heard the woman cry, and once saw her tied to a tree in the defendant's garden.

The Eucalyptus as an Insectifuge.

The *Garden* quotes from a private letter a statement that the placing of a young plant of eucalyptus in a bedroom infested with mosquitoes has been found sufficient to cause the disappearance of the insects.

Testimonial to Dr. Maurice Corr.

In a notice of a proposed memorial to Dr. Maurice Corr, of Dublin, which we printed last week, it was inadvertently stated that the Council of the Irish College of Surgeons "found they could not give effect, in consequence of the legal obligations of their charter," to a recommendation from the College that they should remunerate Dr. Corr for past services to the profession in Ireland. It is true that the Council were so advised, but were informed that they might utilise Dr. Corr's services in such capacity and at such salary, as a College officer, as they might think fit. Feeling bound to make an effort to carry out the recommendation of the Fellows of the College, they appointed Dr. Corr Secretary of the Building Committee, at a salary of £70 a-year, which salary he now enjoys.

The New Dental Society.

The new Dental Society, upon whose formation we commented a few weeks ago, has now been organised. It is called the Association of Legally Qualified Dentists, and the chief of its objects are to be "the establishment of an improved code of ethics; the endeavour to encourage a higher educational standard, both general and professional, for those who may hereafter practise the special branch of dental surgery; and the furtherance of modes of practice compatible only with the highest professional status." This authoritative explanation merely strengthens the opinion which we expressed on the former occasion, namely, that the Association is quite uncalled for, can do no good, and, on the contrary, must do harm, by causing dissension in the profession, and weakening the power of the Odontological Society. The latter Society comprises all the eminent dental practitioners, and most of those practising dentistry as professional men. To this Society dentistry owes, unquestionably, its present respectable position in this country as a recognised special department of the medical profession. The labours of the founders of this Society resulted in the establishment of the licence in dental surgery of the College of Surgeons, the organisation of efficient schools of dental science, and the attraction to the speciality of an increasing number of highly educated and qualified practitioners. The laws of the Society are as strict in enforcing professional conduct as those of any medical society; and we can assert that, in administering these laws, there has been constant watchfulness, so that the Society forms a body of strictly professional men, favourably comparable with any similar association. Some of these gentlemen are without any recognised qualification, some possess only the diploma in dental surgery, whilst a fair proportion have medical and surgical degrees, and a few

the highest scientific qualifications. The Society unites all that is good in the dental profession, and the work that it has already done is a guarantee of its capabilities of achieving more in the same direction. The new association sets out ostensibly to further the same objects; but it is difficult to understand how its promoters hope to do more as a separate body than could be realised were they to direct their energies through the older society, and with the co-operation of those eminent practitioners who have successfully devoted much of their lives, with great self-sacrifice, to the advancement of their profession. The promoters of the new association are seven in number. Four of these have throughout either held aloof from or openly opposed the various movements which have resulted in dental reform. It is difficult, with our present information, to discover the motives of the remaining three in uniting themselves in this venture, and we trust it is not too late to hope they may perceive the anomaly of their position and retire from it before irreparable mischief has resulted. Whilst it would be unjustifiable to impute to these gentlemen any motive but a desire to benefit their profession, it must be admitted that the unfortunate and ill-advised method of procedure adopted in starting the new society furnishes an excuse for the indignation which has been aroused, and the unflattering comments which have been evoked. It is justly pointed out that if the desire had been really to form a representative association of qualified dentists, the proper course would have been to have convened a general meeting to consider the subject. Instead of this, four or five practitioners, having assembled and discussed privately the matter in hand, unhesitatingly set themselves up as a representative body. Such a course could not be defended even were those engaged unquestionably leaders in their profession, and it becomes somewhat offensive when they have no claim to assume any position of authority, being with two exceptions either comparatively young or entirely unknown and untried men. Those who are acquainted with the politics of the dental branch of the profession, who are aware of the difficulties with which the pioneers of progress in their department have had to struggle, and who appreciate the necessity for union and co-operation, will perceive that the mismanagement to which we refer is alone extremely deplorable.

Two more deaths are reported from the milk fever epidemic, one in Bolton and the other in Halliwell, a neighbouring village.

We regret to learn that Mr. Henry Arnott, Assistant Surgeon to and Lecturer on Anatomy at St. Thomas's Hospital, has resigned his appointment owing to failing health.

Dr. Habershon will lecture at the Royal College of Physicians of London, on the Pathology of the Pneumogastric Nerve, on March 31st, and April 5th and 7th, at five o'clock.

Dr. Robert Liveing, one of the Physicians to the Middlesex Hospital, has resigned. The appointment will probably devolve on Dr. Cayley or Dr. R. King, next in succession as Assistant Physicians.

The staff at Charing Cross Hospital will be the poorer for the resignation of Mr. Fairlie Clarke, who is giving up consulting in London, for general practice at Tunbridge Wells. Mr. Clarke's hospital career has proved him to be a trustworthy surgeon and a consistent lecturer, and the institution from which he disconnects himself will therefore regret the severance.

On Wednesday last the first stone of the New Lambeth Infirmary was laid by Mr. Ward. Owing to the large increase in the population of the parish, which numbers at present some 230,000 inhabitants, it was found that the old workhouse in Prince's Road was quite inadequate for the requirements of an infirmary. It was therefore decided to erect a new infirmary, which would be for the reception and treatment of 357 females and 278 males. The building will consist of six isolated blocks, with medical officer's residence, and all necessary departments. Each block will have communications by corridor. The buildings will be of three storeys, and over 100 ft. in length each block. Arrangement is also made for cases requisite to be isolated. The total estimated cost is £50,000.

Literature.

THE STUDENT'S GUIDE TO THE PRACTICE OF MIDWIFERY. (a)

Dr. Roberts must be congratulated on having written a very useful little manual. The teaching is good and trustworthy, which is more than can usually be said of such manuals; and although the book does not pretend to compete with more extensive and ambitious works, it is well up to the best knowledge of the day, and for beginners is probably much more strongly to be recommended.

The only fault to be found with it is its brevity, which is not usually a thing to complain of in such works, for we see frequently that the writer has been cramped in expressing the fuller knowledge of his subject which he evidently possesses.

Perhaps this may be remedied in another edition, when we trust the publishers will feel justified in according more space to the author.

BRAITHWAITE'S RETROSPECT OF MEDICINE.(b)

This well-known and useful publication keeps up its high character as a reliable chronicle "of every discovery and practical improvement in the medical sciences."

The subscriber to the Retrospect may rely on having skilfully culled for him from among the various Journals, Transactions, and publications of all kinds, everything of value that has a practical bearing on professional work; and as the book is in a handy form, he may put it in his pocket and read a bit here and there, as time and opportunity may offer. All the recent advances in medical, surgical, obstetrical, physiological, and other sciences ancillary thereto are noted, and especially, we think, therapeutical matters are well attended to. It is a useful record of recent work.

(a) "The Student's Guide to the Practice of Midwifery." By Dr. Lloyd Roberts. London: J. and A. Churchill. 1876.
(b) "Braithwaite's Retrospect of Medicine," July to December, 1875. London: Simpkin and Co.

Medico-Parliamentary Intelligence.

HOUSE OF COMMONS.—Friday, March 24th.

MEDICAL OFFICERS OF THE ARMY AND EXCHANGE.

Mr. Hardy informed Mr. Dunbar that no right of exchange existed anywhere, because it was a matter of commission. But with respect to medical officers, every application for exchange was carefully considered and decided on its own merits; as a rule no application of a medical officer was refused; and he did not, therefore, propose to make any alteration on the subject.

VIVISECTION.

In reply to Mr. Watt, Mr. Cross said that the Government did not in any way underrate the very important evidence which had been taken by the commission on vivisection, but at the present moment he could not do more than give the hon. gentleman an assurance that the subject would receive the serious attention of the Government. He could not promise that any immediate legislation would be attempted upon the question.

ANTI-VACCINATION.

Replying to Mr. Pease, Mr. Sclater-Booth said that, except by the notice of the hon. gentleman's question, his attention had not been called to Mr. Milner, chairman of the Keighley board of guardians, who had been committed for ten days' hard labour for the non-payment of a fine of 10s. for the non-vaccination of a child. No one regretted more than himself the necessity of prosecution under the vaccination acts, especially where the offence was repeated a number of times. But when his hon. friend put forward the case of a chairman of a board of guardians as especially worthy of the notice of the house, he must remind the hon. member that it was the duty of a chairman of a board of guardians to enforce the acts, and not set an example of disobeying them. The payment of a fine would at any moment have released Mr. Milner from prison. With regard to any alteration in the law, he did not think that Parliament would agree to such a proposal.

CORONERS IN IRELAND.

In answer to Mr. O'Shaughnessy, Sir M. H. Beach said that the Government did not contemplate moving for a committee during the present session to consider the advisability of legislation on the office of coroner in Ireland.

Obituary.

SIR JOHN CORDY BURROWS, KT.

We regret to announce the death of Sir John Cordy Burrows, Kt.

Sir John, who was a Fellow of the Royal College of Surgeons of England, was Consulting Surgeon to the Hospital for Sick Children at Brighton, where he had for many years enjoyed a lucrative practice. He was a man of great perseverance and energy, and of a genial disposition, and was well known in Sussex as a promoter of every undertaking which concerned the elevation of the masses. He had more than once served in the capacity of Mayor of Brighton, and for the part he had taken in improving that town and benefiting his fellow-townsmen, he received from the inhabitants a testimonial, consisting of a carriage and pair of horses, together with a silver model of the Victoria drinking fountain, which he had been instrumental in erecting in the Steine. At the same time Lady Burrows was presented with a silver tea and coffee service. He was knighted in 1873.

Sir John was Surgeon to the 1st Brigade Sussex Artillery Volunteers, and in virtue of his occupying that position, it was his custom to invite, at a great cost, all volunteer medical officers to a *déjeûner* on the numerous field-days held at Brighton. He took a great interest in the British Medical Association, of the S.E. branch of which he was president, and at the last meeting of the Association in Edinburgh he was elected to be president at the meeting to take place in Brighton next August.

Sir John had been ailing for some weeks past, and he died at his residence at Brighton on the 25th March, at the age of 63, leaving a widow and one son.

SIR J. W. FISHER, F.R.C.S.

Another of the few remaining links of the profession with the past century has just been severed by the death of Sir John Fisher, which occurred last week at his residence in London.

The deceased knight had arrived at the patriarchal age of 88 years, the diploma of F.R.C.S. Eng. (Hon.) having been conferred upon him as far back as 1809. Oddly enough, in the very machine-room where The Medical Press and Circular is now printed Sir John attended his first anatomical lectures, under the celebrated Hunter, when subjects for dissection were more easily obtainable than now. He was educated at the St. George's and Westminster Hospital Schools, and was a Fellow of the Medico-Chirurgical and the Medical Societies of London.

NETLEY HOSPITAL.

It is stated positively by a contemporary that the Army Medical School at Netley is about to be abolished. There have for some time been floating rumours of this intention, and it seems consistent with Mr. Gathorne Hardy's policy, which is to get the army medical work done in the cheapest way and by the cheapest hands, no matter by what means. At the time when Lord Herbert founded the school, the profession was full of doubt as to the necessity for it and its usefulness; but those doubts have been long since dispelled, and every one now feels that the probation of the army surgeon at Netley was the most valuable part of his education, without which he would enter the service in ignorance of the speciality in which he was to practise, and unacquainted with the manners and customs of his *confrères*.

The abolition of Netley School—if it should be carried into effect—will deal one more blow at the efficiency of the Army Medical Service, because it will cause the medical cadet to enter upon charge of his regiment and into association with his brother officers as an absolutely raw recruit, with whom—until he has qualified himself in army customs—no intimacy on the part of his brother officers can exist, and to whom his military duties are a hidden mystery.

We have grumbled at the wooden immovability of King Log Cardwell, but it was perhaps preferable to the erratic flights of King Stork Hardy.

SCIENTIFIC GRANTS.

At the last meeting of the Committee of Council of the British Medical Association the following scientific grants were made on the recommendation of the Scientific Grants Committee, in addition to those granted in August last, making a total for the year of £268. Professor Rutherford—a further grant of £80, in addition to £20 granted at the last meetig, for researches on the Biliary Secretion. Dr. McKendrick—£30 for researches into the Antagonism of Medicines, and £10 for researches on the Dialysis of Blood. Dr. Alfred Galabin—£15 (or £20 if required) for investigations in Pulse Curves

especially in relation to such states as Fever and Bright's Disease.

We congratulate the Association on the growth of its liberality in the cause of science. Even these pittances expended by the hands of zealous students will do something to give the organisation a scientific character and to redeem it from the opprobrium of being simply a co-operative pic-nic and printing society. If the Council could spare say even a tenth of the income of the Association for the purposes of scientific investigation, great results might be achieved; but such a grant would be too much to spare from the all-absorbing appetite of the Association's journal.

THE WESTMORELAND LOCK HOSPITAL, DUBLIN.

THE election to the Surgeoncy of this institution, vacated by the death of Dr. Morgan, will take place on Saturday next. The selection will probably be made between Dr. Macnamara, Dr. Peele, Dr. Mapother, and Dr. Martin, but Dr. Meldon, Dr. Tweedy, and many others are competitors. We are able to state that Dr. Wheeler, of the City of Dublin Hospital, is not a candidate.

NOTICES TO CORRESPONDENTS.

☞ CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

NOTICE TO SUBSCRIBERS.—The Publishers will be glad to receive the subscriptions for the past year, 1875—£1 2s. 6d. Subscriptions in advance for 1876, at the reduced tariff of 21s. per annum, post free, must be paid before the end of this month in London, Dublin, or Edinburgh.

READING CASES.—Cloth board cases, gilt-lettered, containing 26 strings for holding each volume of the MEDICAL PRESS AND CIRCULAR, can now be had at either office of this Journal, price 2s. 6d. The postal regulations not allowing the Journal to be stitched, these cases will be found very useful to keep each weekly number intact, clean, and flat after it has passed through the post.

WE are requested to state that Dr. John H. Clapman, 60 Pembroke Road, Dublin, HON. SEC. of the Irish Medical Association, has been appointed Treasurer to the Association, *ad interim*, in the room of Dr. Morgan. Subscriptions will be gladly received and duly acknowledged by him; and it is requested that members will be kind enough to send their subscriptions for the current year as soon as convenient.

A POOR MEDICAL STUDENT.—We have to acknowledge the receipt of one guinea from "Five Friends," Abersychan, Wales, towards the appeal which appeared under the above heading in our last.

BRITISH FREEDOM UNDER VICTORIA.—Post-cards are being sent all over the country containing paragraphs under the above heading, with violent denunciations of the despotic nature of the laws which compel the vaccination of children against the consciences of their parents. The cases cited occurred in Sheffield, where two persons were fined in the full penalty and costs for neglecting to comply with the vaccination. We commend the magistrates for their firmness in refusing to listen to the fanatical appeals of the anti-vaccinationists, the head of whom is the Rev. Hume-Rothery, who is sending round these mischievous post-cards.

MR. C. J. P.—The request shall be attended to when opportunity offers.

DR. G. M. H. is thanked for his letter, which he will find noticed elsewhere.

DR. HABERSHON will lecture on Friday afternoon next, at 5 p.m., at the Royal College of Physicians of London, "On the Pathology of the Pneumogastric Nerve."

CREPITUS IN OVARIAN TUMOURS.

To the Editor of the MEDICAL PRESS AND CIRCULAR.

SIR,—Mr. Croly, in his reply in the debate on his case of ovariotomy, seems ignorant that the presence of crepitus means that the two peritoneal surfaces are rubbing on one another, and therefore that they cannot be adherent.

I am, &c.,
F.R.C.S.

VACANCIES.

King's College Hospital.—Assistant-Surgeon. Honorary. Applications to the Secretary at the College, Strand.

St. Thomas's Hospital.—Assistant-Surgeon, honorary; and an Apothecary. Full particulars to be obtained on application.

Middlesex Hospital.—Physician. Honorary. Particulars of the Secretary.

St. Mary's Hospital, Paddington.—Lectureship on Botany. Particulars of the Secretary.

Brompton Consumption Hospital.—Resident Clinical Assistants. Full particulars of the Secretary.

Argyleshire. Rural Parish on Mainland.—Medical Officer. Salary, £100, with residence. Private practice allowed. Address M.D., Western Club, Glasgow.

Parish of Wig, Isle of Lews, Scotland.—Medical Officer. Salary, £150, with fees extra, and private practice allowed. Address the Inspector of the Poor, Stornoway, N.B.

Essex Lunatic Asylum.—Second Assistant Medical Officer. Salary, £100, with board, &c. Apply to Dr. Campbell, County Asylum, Brentwood.

Gloucester County Asylum.—Senior Medical Assistant. Salary, £150 per annum, with board, &c. Address the Superintendent of the Asylum.

Suffolk Lunatic Asylum.—Medical Superintendent. Salary, £400. Applications to be addressed to the Clerk of the Peace.

Notts County Lunatic Asylum.—Assistant Medical Officer. Salary, £100, with board. Address Dr. Phillimore, Snenton, Notts.

Birmingham General Hospital.—Registrar and Pathologist. Salary, £130, with board and residence. Applications to the House Governor.

Birmingham Free Hospital for Sick Children.—Resident Medical Officer. Salary, £80, with board and residence. Applications to be addressed to the Committee.

Warneford Hospital.—House-Surgeon. Salary, £100, with board and residence. Applications to the Secretary of the Hospital, Leamington.

Boston Union.—Medical Officer. Salary, £115, with extra fees. Address the Clerk of the Union, Boston, Lincolnshire.

Carlow Union, Bagenalstown Dispensary District.—Medical Officer. Salary, £100, with an additional £20 as Sanitary Officer. (See Advt.)

APPOINTMENTS.

BRUNTON, J., M.A., M.D., Examiner in Midwifery and Medical Jurisprudence in the Glasgow University.

COOPER, J. N., L.K.Q.C.P., House-Surgeon to the Pendleton Branch of the Salford Royal Hospital and Dispensary.

GRAHAM, J., M.D., C.M., Medical Attendant to the Royal Irish Constabulary, Killough and Ardglass.

GREENE, J. S., M.R.C.S.E., L.S.A.L., Medical Officer for the No. 3 District of the Newport Union, Salop.

M'DIARMID, Dr., Medical Tutor at the University of Durham College of Medicine, Newcastle-on-Tyne.

MARSH, E. A., L.S.A.L., Junior Resident House-Surgeon to the Torbay Infirmary, Torquay.

MORISON, A., M.B., C.M., Honorary Medical Officer to the Holloway and North Islington Dispensary.

NORTH, J. C., M.B., Medical Officer to the Brecknock Union Workhouse.

POWELL, E., M.R.C.S., L.S.A., First Assistant Medical Officer to the Kent County Lunatic Asylum at Barming Heath.

RENTON, J. C., M.B., L.R.C.S.E., Assistant-Surgeon to the Glasgow Eye Infirmary.

SANDERSON, J. B., M.D., F.R.S., Examiner for the Natural Sciences Tripos, University of Cambridge.

SHEPPARD, W. A., Apothecary to the County Infirmary, Kilkenny.

YOUNG, A., B.A., L.S.A.L., Second Assistant Medical Officer to the Kent County Lunatic Asylum, Barming Heath.

Deaths.

BANKS.—On the 15th March, at Southsea, George Fletcher Banks, M.R.C.S.E., Fleet-Surgeon R.N., aged 52.

BLOXAM.—On the 11th March, at Ryde, Isle of Wight, John Charlton Bloxam, Surgeon, aged 69.

BURROWS.—On the 25th March, at his residence, 62 Old Steyne, Brighton, Sir J. Cordy Burrows, F.R.C.S., thrice Mayor of Brighton, aged 62.

COLLINS.—On the 17th March, at Sherborne, Edwin Stephens Collins, M.R.C.S.E., aged 50.

CROOME.—On the 20th March, at Middleton-Cheney, Robert Croome, M.R.C.S.E., aged 81.

DEWAR.—On the 18th March, at Glasgow, Donald Dewar, M.D., aged 50.

EMPSON.—On the 12th March, at Kilkenny, Richard Empson, L.A.H.D., aged 52.

FISHER.—On the 22nd March, at his residence, Grosvenor Gate, 33 Park Lane, W., Sir John William Fisher, M.R.C.S., aged 88.

HOLLAND.—On the 21st March, at St. Chad's, Lichfield, suddenly, Charles Holland, M.D., D.L., F.R.S., in his 75th year.

HUDSON.—On the 13th March, at Walsingham, Peter Hudson, M.R.C.S.E., aged 64.

PILKINGTON.—On the 11th March, at Carrick, Queen's County, George Pilkington, L.K.Q.C.P.I., aged 48.

WELD.—On the 17th March, at Hurstmonceaux, Sussex, George Henry Weld, L.R.C.P.L., aged 43.

ON TUBERCULOSIS IN CHILDREN AND THE CONDITIONS WHICH RESEMBLE IT.

By W. H. Day, M.D., M.R.C.P.Lond.,

Physician to the Samaritan Hospital for Women and Children.

(*Continued from page* 255.)

"Catching cold" is so constantly assigned as the starting point of active pulmonary disease, that we cannot escape from the conclusion that it is no mean factor in the active development of tuberculosis. There is a case recorded by Dr. Herman Weber (*a*) of a boy, ten years of age, the son of healthy parents, who had an ordinary sore throat, in August, 1871. This was followed about the twelfth day by pain in the right side of the throat, extending to the ear, and causing deafness; the tympanic membrane became yellowish and prominent, and Dr. Weber suggested that it should be perforated, and if the advice had been carried out it might have saved the child's life. In November, 1870, he began to cough, and was sick and feverish; the pulse was 130, and the temperature 103 deg. The chief symptoms were headache, sleeplessness, constipation, and dry cough; crepitant rhonchi were heard, but no dulness. There was deafness, but no discharge from the ear, and the urine was non-albuminous. There were two temperature elevations every day between 103 deg. and 105 deg. and two depressions to between 98 deg. and 100 deg., and the pulse varied from 65 to 160 in the minute. The boy died November 26th, and during the last few hours of life the temperature rose from 101 deg. 5 min to 106 deg. On a post-mortem examination, grey miliary tubercles were discovered in the pleura, pericardium, liver, and meninges of the brain. The right temporal bone and internal ear were normal, but the tympanic cavity was filled with soft caseous matter.

Indifferent health may be present in a large number of cases for years, and the patient may remain free from any actual disease; but when exposure has led to cough and febrile symptoms, then ensue the usual signs of bronchitis, accompanied with expectoration. No dulness is to be detected below the clavicles at first, or above the spine of the scapula; but, at a later period, this significant sign is added to the rest, and we are irresistibly led to believe that we are dealing with a case of phthisis, originating in catarrh. In many young persons, when the chest sounds clear on percussion, and there is bronchitis of all diameters of the bronchial tubes, the lungs are found studded with miliary tubercles after death. Death has been so rapid in many instances, that the development of these granulations to have reached such a mature stage, must have preceded the last inflammatory attack. The diminution of resonance (often absent) does not become apparent in these cases till the bronchitis has existed for some considerable length of time. I do not think that this view altogether invalidates the doctrine that the tubercles may not have initiated the bronchitis; and on this point I shall invite your opinion and discussion, for I am free to confess that my mind is not entirely settled on this important question of cause and effect, nor do I see anything in the etiology of the disease why it should follow any uniform or fixed law. The same causes originate varied affections, modified by susceptibility and constitution though not following the same chronological order.

In the progress of ordinary phthisis, which continues for years, each fresh attack of tuberculosis is preceded by bronchitis. It is of common occurrence to meet with persons who have dulness under one clavicle, harsh or feeble respiration, defective expansion, and prolonged expiration. Such a patient takes cold or gets wet through, when the dulness on percussion is increased, and the inflammatory process leads to a further deposit of tubercle, or if a female, she may be the subject of a local disease, which keeps up

(*a*) "Clinical Transactions." Vol. viii., 1875, page 135.

the pulmonary mischief, and even if it can be removed the shock to the system may further reduce it, and determine the fatal event. A patient, aged fifteen, suffering from ovarian disease, was admitted into the Samaritan Hospital, under the care of Mr. Spencer Wells, on the 8th December, 1874. She had been subject to cough all her life, and latterly, in summer as well as in winter, but she had only recently expectorated, and had never had hæmoptysis. She was a person of nervous temperament, and any fatigue or excitement increased her cough; she had a wan and delicate look; her lips were inclined to a dusky pallor, and the tips of her fingers were bluish. Below the right clavicle, to the lower border of the third rib, a distinct bubbling crepitant rhonchus was heard on inspiration. In the right supra spinous fossa, the percussion note was dull, with prolonged vocal resonance; deep inspiration, too, was attended with small and large liquid crepitation throughout both backs. The temperature was normal, the pulse averaged from 84 to 88, and the respirations were 16; the heart's sounds were normal. On the 2nd of January, 1875, the bronchial irritation continued, and 14½ pints of fluid were removed by tapping, with so much relief to her pulmonary symptoms, that four days later (January 6th) she was successfully operated on. The lungs then scarcely indicated any deviation from health, except the consolidation above the spine of the scapula, as I have before mentioned. On the morning after the operation she complained of much oppression of the chest, and sonorous rhonchus was heard throughout the pectoral region. On the following day she was weak and exhausted, and had great difficulty in expectorating some scanty frothy sputa; loud mucous râles could be heard all over the room; the skin was perspiring; the temperature, 101 deg. 6 min.; pulse, 140; respirations, 24. On the 9th, the sputa were diminished and purulent, and the temperature next day had reached 102 deg. 6 min., in spite of four doses of aconite. On the 10th, the patient was seized with free epistaxis twice during the day, and the bowels moved of themselves four times freely. On the 11th, the temperature was 102 deg. 8 min; pulse, 124; respirations, 32. As there was nothing in the wound to cause this, it was thought that her lungs were seriously involved, and that she might be suffering from some complicated pneumonia. A careful examination of the posterior lobes of the lungs (not always easy to make after ovariotomy) proved that they were resonant throughout, and that the vesicular murmur was everywhere distinct: she expectorated some purulent sputa, not in the least frothy; the temperature had fallen to 101 deg.; pulse, 124; respirations, 32. On the 14th, the cough was incessant, but the sputa freely coughed up, the larger bronchi being only involved: the morning temperature, which was only 99 deg. 8 min., rose to 102 deg. 8 min. in the evening, and there was some amount of dyspnœa. This great difference between the morning and evening rise was a most significant sign. On the 18th, the temperature was 99 deg., and the pulse, 82; a good deal of purulent matter was expectorated with considerable cough. She went to a convalescent home at Brentwood. Three months ago I heard that this patient died of pneumonia, in Oxford, six months after the operation This was, I think, a case of tuberculosis, influenced by the local disease in the abdomen, to such an extent, that had the patient escaped ovarian trouble, she might have lived on for many years. As it was, her life was unquestionably prolonged by the operation.

When tubercle is being deposited in the lung, bronchitis is one of the most common attendant symptoms in young subjects. If the bronchitis is persistent, and does not yield as readily as the uncomplicated affection, it is suspicious of tuberculosis; when tubercle is disseminated equally through the pulmonary organs, there is sometimes wanting the sign of consolidation, and this is apt to lead us astray. In a depraved state of health the formation of tubercle takes place rapidly or slowly, and general crepitation may be detected throughout the chest: but there may be neither dulness nor prolonged expiration of the breath. There is but little cough, and, if the subject is young, the expectoration is swallowed. The pulse and respiration may not be greatly accelerated, nor is the temperature in the early stages above the normal standard. Yet, as the disease advances, these last symptoms become more developed, hæmoptysis occurs, the lips become livid, the extremities cold, and delirium may supervene. These are, of course, rapid cases, and strictly bear the name of acute phthisis.

The glands which lie near the bifurcation of the trachea in children are very liable to contain tubercular matter, and they may reach the size of a hen's egg or even larger. I have now a child under my care in whom the signs of *bronchial phthisis* are well-marked; the breathing between the scapulæ at the upper part is bronchial and almost amphoric, and the percussion note hyperresonant. Where the glands are softening it is not unusual to meet with a clear defined tympanitic note in this situation, and this arises where there is no consolidated lung between the cavity and the posterior wall of the thorax. When the child cries or coughs, the voice is conveyed to the ear with extraordinary power, just as though it was transmitted direct from the larynx or trachea in which it was formed without getting into the bronchi at all. Calcification is, however, much more common than softening of the bronchial glands. But in making a diagnosis it should be remembered that we often meet with dulness in the interscapular space from enlargement of the tubercular glands near the spinal column, and hence a wooden or cracked pot sound is elicited on percussion. This sound is also occasionally caught in front, at the upper part of the sternum, when the enlarged glands lie under the anterior margin of the lungs.

Febrile symptoms are significant, and when the attacks are severe or frequent they will generally be found dependent on the rapid formation of tubercles. But persistent feverish symptoms are sometimes met with in young children, when there are no signs of a local character in the chest—no cough, no wheezing—and yet after death the lungs are found to contain tubercles. "I attended a little boy," says Dr. James Russell, of the Birmingham General Hospital, "aged six, with one of the most experienced surgeons of this town. His illness lasted for eight weeks; my attendance comprised the last week only. His sole symptom was persistent feverish reaction, though with scarcely any delirium; the one single symptom of a local character was constant rapidity of breathing. The child's chest was searched over and over again, both by my colleague and by myself, for any indication of disease, but, to the very last, percussion was normal; not even a wheeze could be discovered; and there was entire absence of cough and expectoration. Death was rather sudden, I suspect from fainting. On examination, both lungs were positively filled with tubercles. (*a*) No mention is made of the temperature, but the feverish reaction and rapid breathing were very significant. If the half of one lung is obstructed in its functions, by the rapid development of tubercles, they must occasion serious mischief by diminishing the power of the respiratory apparatus. In some cases where the production of tubercles is rapid and general, a state of tubercular asphyxia takes place, and embarrassment in breathing bordering on suffocation from imperfect respiration, without suppuration in the lung, or the usual symptoms of phthisis.

What is the pathology of such a frequent case as this? A young person takes cold in winter, and is seized with cough: spitting and dyspnœa. During the cold weather he is tormented with his ailment, and cannot lose it till the warm weather returns. The patient appears in good health, and has not lost flesh or strength: he relishes and digests his food, and there is neither sweating or diarrhœa. He is well in the summer, but every winter has a return of the symptoms, and each succeeding attack is more

(*a*) Braithwaite "On Fever and Bronchitis as early signs of Phthisis." Vol. lxi., p. 70. 1865.

troublesome to shake off than the one that has preceded it. By-and-by the disease does not subside in the summer, and there are added general and physical signs, which prove the serious nature of the affection: he now slowly begins to lose flesh and strength, and the expectoration becomes thicker and purulent; dulness is detected in one or both apices of the lungs, followed by softening, and a fatal termination.

So much for bronchitis as a cause; but let me add a word or two on tuberculosis having its origin in pneumonia or parenchymatous inflammation.

E. F., aged twenty, well made and rather muscular, but with fair eyes and light hair, caught a cold on the 22nd of October, 1874, followed by a severe rigor; pain came on in the right side (pleuro-pneumonia), and extended to the abdomen. The left lung was also slightly involved, and for a long time the sputa were rusty and varnish-like. At the consultation to which I was summoned to meet the two medical men in attendance, I found that leeches had been applied, followed by a blister, and calomel and opium had been given, but not enough to affect his gums. I found him sitting up in bed, with a pale, nervous, and anxious look; there was a little viscid bronchial secretion, nith a thin streak of florid blood, but not mixed with it. wn the right side, from the clavicle to the nipple, the dul- Oess was considerable, and the breathing tubular, abrupt, and divided; the heart's sounds were conveyed to the ear with unnatural intensity, and the vocal fremitus was greatly increased. Posteriorly the dulness extended from the spine of the scapula downwards, and only a trace of crepitant rhonchus could be caught on deep inspiration; broncophony was loud and muffled over the hepatised parts, and the character of the respiration was similar to that in front. In the infra-mammary region, at the edge of the axillary border, a creaking sound as of a solid substance slipping over an uneven and elastic surface was distinctly heard on taking a deep breath. We agreed to resume small doses of mercury, and to apply a succession of blisters over the back of the affected lung. Resolution commenced slowly, and the patient went on satisfactorily, and left for Torquay at the end of a month from my visit. There was sufficient exudation into the pulmonary tissue, and plastic deposit coating its pleural investment after six weeks of acute illness, to lead me to dread the possibility of future tubercular change, and from the lingering delicacy of constitution which remained many months afterwards, we might well be apprehensive that the lung had not yet returned to health and activity.

I am not sure that the means employed to reduce pneumonia in some constitutions may not prostrate the vital powers, and lead to degeneration of the effused lymph, which otherwise might become organised and cast off in the healthy progress of the disease. No problem in medieal practice demands more consideration for its solution than that which requires us quickly to determine at the bedside how far we may safely venture with antiphlogistic remedies in acute disease. If active inflammation long assails vital organs like the lungs, and is timidly dealt with, the effused products after a while resist absorption, and become irritating; and if the measures employed are too heroic, then the general strength may either fail at once, or decline more gradually. But a deadly disorder may grow out of the attack. Rare as it is for tuberculization of the lung to succeed pneumonia, recent investigations have shown how numerous are the sources of blood contamination, and from what slight irritation it may arise, and we cannot dismiss the danger from our minds where a large extent of lung is involved in inflammation, even if no predisposition exists.

Symptoms.—It is a distinguishing feature of tuberculosis in childhood that several organs may be affected at one and the same time—the lungs, the liver, the pleuræ, the spleen, kidneys, and peritoneum, when special symptoms common to disturbance in any of these organs become developed. The general symptoms, however, may be present for an indefinite period without our being able to trace any local lesion; and when this is so, as we shall presently see, the elevation of temperature is the only reliable ground for diagnosis. The symptoms will vary according to the seat of the tubercular lesion. Among the earliest I have noticed is pain in the stomach and indigestion, the child being frequently brought under our notice by his parents for this solitary symptom, when the more general and common features of the disease, as loss of flesh, thirst, and evening paroxsyms of heat have not yet indicated its approach. I have particularly noticed this symptom of gastric pain, and occasionally vomiting, among my youthful out-patients, even in those exceptional instances where I have had reason to think considerable care has been bestowed on diet and regimen. For weeks together I have known this symptom continue, and whilst it lasts digestion and assimilation are interfered with, and the children have a pinched and exhausted look, and lose flesh quickly. It demands attention and care, for it may be the evidence of tubercular mischief springing up in the abdomen or peritoneum, when the lungs are free from any infiltration of it.

Among other common symptoms is a capricious and irregular appetite: sometimes it amounts to hunger, and at other times food is so disliked that the weak stomach can retain it only for a short time. When the meal lies undigested in the stomach for an unusual time, it creates flatulence, pains, acid eructations, and diarrhœa. The motions vary in colour and consistence, sometimes being deficient in bile, and costive or loose; at other times they are dark, or have a glairy appearance resembling the white of an egg; the urine is acid and turbid on standing, throwing down pink, or even white lithates; the tongue is glazed or furred at the dorsum, or it is of a bright red at the tip and edges, the papillæ being prominent. When the appetite is capricious there is a dislike for any fatty kind of food, thirst is commonly present, and the pulse is habitually quick and weak. If the local symptoms remain obstinate a state of hectic fever is established, and under emaciation, high temperature, and diaphoresis, the patient gradually dies with the local determination of tubercle to some special organ, as the lungs, brain, or peritoneum.

Temperature.—Wherever the deposition of tubercle is taking place in these cases, the temperature gradually increases in elevation, and the destructive changes in the lung continue. Of 24 cases recorded by Dr. Ringer, in which tubercle was being deposited, in 21 there was a continued elevation of the temperature of the body, and in these 21 cases the deposition of tubercle was proved, during life, by increase of physical signs, or after death by the post-mortem appearances. (*a*) The temperature, according to some observers, has been noticed not to exceed 99 deg. in some cases of acute tuberculosis, and that in the evening, when the maximum temperature is usually attained. I have never met with such a case; and here I would give my own experience, that the temperature has been persistently higher in the evening than in the morning. But when this process of deposition has ceased, the lung becomes tough and puckered, and the cavities lined with fibrous walls, whilst the temperature falls to the normal point. So it seems evident that, when the granulations have undergone this change, or have become quiescent and ceased to irritate, tuberculosis is curable. These cases are not unusual. Bronchitis, which is so commonly associated with softening of tubercle, and recognised by rhonchus and moist sounds, is a symptom to be expected and watched for. Here we have a rise of temperature proportionate, probably, to the tubercular infiltration and the bronchitis set up by it, though there may not be enough to interfere with the proper aeration of the blood, or to excite cough or dyspnœa. In severe cases of ordinary bronchitis, accompanied with dysnœa and other signs of obstructed circulation, there is no necessary elevation of temperature.

Small deposits of tubercle, when scattered through a

(*a*) "On the Temperature of the Body as a means of Diagnosis in Phthisis and Tuberculosis. Walton and Maberly. 1865. P. 5.

considerable portion of the lung, are not to be detected by physical signs, and we may not suspect such a condition till a disease like pneumonia or pleurisy sets in. Most of the symptoms of failing health and delicacy in a young person are put down to some change of constitution in the absence of frequent cough and expectoration, but the mischief has long been resident in the lungs, and the inflammatory attack was only wanting to rouse the graver evil. Some years ago I met with a young person who caught cold, and got an attack of pneumonia. There were frequent dry cough, hurried bronchial breathing, accelerated pulse, wasting, and high temperature, but no expectoration or moist rhonchi. Percussion was dull, and bronchophony was general over the posterior surface of the lungs. The patient apparently recovered, but two years later died with all the symptoms of pulmonary tuberculosis. For years she had been delicate, and her family feared she might die consumptive, but one medical man after another assured them there was no deposit of tubercle. There are many cases of children dying of tubercular meningitis, in whom tubercle is also met with in the lungs and peritoneum, who have exhibited no symptoms of its presence during life, and yet after death it is found so abundantly scattered through these organs, that it becomes a mystery how it was that we did not discover the morbid changes that were going on by some general or physical signs. Even the cerebral symptoms are sometimes so rapid and unexpected that the source of mischief must have been lying dormant for some considerable time.

When, moreover, it happens in tuberculosis that the weight of the body is kept up, and this is not unusual if the appetite is good, and there is no exhausting diarrhœa going on, we are the more driven to rely on a continued elevation of temperature as the only sure point of diagnosis in doubtful cases. For a considerable time the temperature may continue high, and the weight of the body remain undiminished, as in many cases of ordinary and advanced phthisis, the patients retain their weight when eating well and taking cod-liver oil. But this symptom would not justify us in concluding that the disease was arrested, or even present, unless physical signs were present also, and showed improvement. It will be acknowledged that when patients with considerable lung disease are progressing most satisfactorily, if the physical signs show no abatement in severity, they are liable at any moment to a relapse with the complications of profuse expectoration or hæmoptysis. In these cases, if we had watched the physical symptoms, we could scarcely have been unprepared for the changes. For instance, a man who died in August 1875, aged 44, kept up his weight till within two months of his death, though the physical signs went on increasing till the greater portion of the right lung was useless as a breathing organ, but he took no exercise, and was most carefully watched during his illness, and supplied with every conceivable form of nourishment. Whenever in violation of the orders given, he ventured out for a walk and became fatigued, he was thrown back for some days.

The temperature in tuberculosis is subject to so much variation that a large field of observation is required to draw any practical conclusions from it, and cases require careful and diligent watching. When in any given case of illness in a young person, the temperature is daily elevated for a considerable period, and is not due to rheumatism or to ague, we may suspect tuberculosis, even if the general symptoms scarcely point to the possibility of this condition. We must be sure that the thermometer is correctly registered before it is placed in the axilla, and that the arm is kept well against the side for ten minutes or a quarter of an hour. The temperature is said to be so slightly altered in some cases that it scarcely exceeds the normal standard, but my experience induces me to think that it never remains so long if tubercle is being deposited. Soon the evening temperature is slightly elevated, and later on in some instances there is a rise in both the morning and evening temperature. At mid-day or about 5 p.m., we often observe a regular and well marked rise, varying according to the activity of the disease.

Dr. Wilson Fox (*a*) says that "Lebert found in 22 cases the mean evening temperature of acute tuberculosis was as follows:—In 2 not exceeding 100°4′; in 8, including those last mentioned, not exceeding 102°2′; in 9, more than 103°4′; in 4, from 103°4′ to 104°; in 1, from 104° to 105°5′." Dr. Fox found that a temperature of 104° was not exceeded by 62·5 per cent. in acute tuberculosis, and by 36 per cent. in acute phthisis. Temperatures exceeding 105° with two exceptions (acute rheumatism and phthisis) are found exclusively in acute tuberculosis. Both Wünderlich and Lebert record cases of hyperpyrexial temperatures before death. The latter mentions one case where it rose to between 107° and 108°, and as we have noticed, the temperature rising high shortly before death in Dr. Weber's case.

The more I have thought and pondered over the fluctuations of temperature in disease, the more I have doubted the possibility of constructing any classification from which to draw any accurate conclusions. Diseases like tuberculosis and phthisis which are usually protracted and tedious, are those generally selected for experiment, but even these give such varying results, that nothing absolutaly definite or uniform can be gathered from them. Patients must live under precisely the same circumstances if deductions are to be of any practical value, the hygienic conditions must be alike, the treatment must be the same, and age and constitutional tendencies must be weighed and balanced. When tubercle is forming the temperature may rise to 106° or more. Dr. Theodore Williams says that it is never higher in the pyrexial cases of acute phthisis, but a few cases are recorded as high as 106°7′. I agree with him that there is often a rise after 2 p.m., or what is frequent about 5 p.m., when at the latter time it not unfrequently rises to the highest point in tuberculosis. It is probable that tubercle may form and the disease advance without any rise, which is perhaps due to exhaustion and collapse.

(To be continued.)

A CONTRIBUTION TO THE HISTORY OF PUERPERAL FEVER.

By W. T. Greene, M.B., M.A., &c., &c.,
Fell. Obst. Society of London.

Although it is yet an open question whether or not there be any specific febrile affection peculiar to parturient women, it is at least convenient, in the present state of our knowledge on the subject, to retain the generic name which usage and the "Nomenclature of Diseases" have rendered familiar to the profession, and, therefore, without admitting its applicability in every instance, I have affixed it to the present paper.

In December last I was called upon to attend a young woman in her second confinement. She was of delicate constitution, hard-worked, and very subject to neuralgia and hysterical paroxysms, which, I have remarked, are not unfrequently coexistent in the same person. The house she lived in was decidedly unhealthy; the drains were badly constructed, and, moreover, a large laundry business was carried on upon the premises, and superintended by my patient up to the commencement of her labour.

She was delivered on the 26th December last, after an easy labour, of a healthy male child, and seemed very comfortable when I visited her again in the evening. Next morning, however, she presented a very different appearance; her face was flushed, her pulse high, temperature over 100°, and she complained of much abdominal tenderness; the uterus was not enlarged, but excessively

(*a*) "On the Temperature, Pulse, and Respiration in Phthisis and Acute Tuberculization of the Lungs." *Med. Chir. Trans.*, Vol. lvi., p. 397.

tender on pressure; the lochia were scanty, and the bladder had not acted since the previous evening.

I prescribed a sedative, used the catheter and the syringe, and ordered poultices to be applied over the abdomen; but my instructions were not efficiently carried out in that respect, and towards evening the patient's condition was very much worse.

Not to enter into any minutiæ, I may state that, after having exhibited, *seriatim*, every symptom usually met with in severe attacks of puerperal fever, with the addition of several seizures of a cataleptic, rather than epileptic, character, and in spite of the remedial measures adopted in consultation with my friend Dr. Gervis, the case terminated fatally on the tenth day after delivery.

The post-mortem examination revealed the intensity of the attack, which was, doubtless, autogenetic or idiopathic in its origin, and influenced in its course by the adverse surroundings of the patient.

During my attendance on this case, and for a fortnight afterwards, I declined all midwifery practice; then, after thoroughly disinfecting myself, I attended three cases on the same day. The first, a primipara, did well and recovered without a single bad symptom; but not so the second and third: they each convalesced very slowly, and caused me much anxiety, but eventually recovered.

The question arises—Had their morbility anything to do with me? Was I the cause of their illness?

I venture to think not. I had used every possible precaution to avoid spreading the disease; and if I were the infecting agent, why should the first have escaped? She was a primipara, it is true, and the others were multiparæ; but is there sufficient in that circumstance to account for the immunity she enjoyed? I can scarcely think so: the antecedent health of all three women was good, and their circumstances and surroundings about on a par.

I am disposed to consider that the disturbing cause in both cases was *mental*, for both my second and third patients were disappointed by their nurses, whose defection, they admitted, annoyed them very much, and inconvenienced them not a little; while the first had the advantage of good and careful nursing, and recovered, as I have said, without a single bad symptom.

TWO CASES OF MILIARY FEVER.

By Thomas P. Tuckey, M.B. T.C.D.
Medical Officer Ballyhooly Dispensary District.

Since I was elected to the above dispensary, some three years ago, my district has been a regular nest of fever (if I may be allowed the expression)—typhoid, of which epidemic I have given a short account in the *Irish Hospital Gazette*. Typhus, and low, or adynamic, or nervous fever, have been very prevalent. I do not intend to say anything of the latter fevers, as they have been described by men in whose presence I feel (for, am I not in their presence when I read their works?) as nothing. Miliary fever, known by the name also of febris vesicularis, sweating fever (der Friesel), febris miliaris (Sauvages), purpura alba, la suette epidémique (Gastellier), and a host of other names, is, from what I can gather, a rare disease in this country, for it is, I believe, different from the fever mentioned by Sir Thomas Watson as miliary fever, which is synonymous with the famine fever of Murchison and the relapsing synocha of Christison, first described by Dr. Rutty, and afterwards by Dr. Cormack. Miliary fever *proper*, that is, the sweating sickness, occurred as a fearful scourge in England in the fifteenth and sixteenth centuries, and also in France in the last century (Boyer).

The two cases of fever I am about to describe were undoubtedly of this type, and not relapsing fever, as there was no return of the pyrexia after an interval of a fortnight. The following were the symptoms:—

Case I.—J. Divane, æt. 45, sent for me on the 10th of October. He complained of the following symptoms:—Lassitude, headache, pains in his bones, nausea, chills, followed by flushing, and loss of appetite.

His temperature was 100°, his pulse full and strong, reminding one of the pulse of acute rheumatism, about 100, but quicker at one quarter of the round of the second dial than at another. Urine scanty and clouded, bowels confined, respiration slightly increased, short and frequent cough, no expectoration, profuse sweating, no sudamina, face flushed, and perspiration rolling down his forehead, tongue furred, yellow, and moist. Ordered—℞ Zinc. sulphat. grs. xxx., emetic tartar, gr. ss.; to be dissolved in a cupful of tepid water. I also ordered him grs. v. of calomel and twenty of compound powder of jalap, to be followed by a black draught.

11th.—Bowels opened, pulse 110, full and strong, headache better, pains in bones gone; slight confusion of thought during morning; last night had unpleasant dreams; deaf, only hears when loudly spoken to, and requires some short time to understand queries; profuse sweating, with an unpleasant sour odour; the bed-clothes are quite wet, and when they are lifted off, quite a steam is perceptible; cough troublesome. Ordered—Turpentine epithem to front of chest, and the following powders:—℞ Pulv. potass. nit. grs. xxx.; pulv. Jacob. grs. vi.; pulv. ipec. grs. xij. Divide into 6 powders; one three times a day.

13th.—Deafness still continues, but patient is sensible, cough better; on examination of chest, bronchitic râles, soft, expectoration somewhat copious. Temperature 101·3°, pulse 106—10, strong, but variable, still full. Urine still heavy, but more copious, acid sweating still profuse. Sudamina, or rather miliary vesicles, over chest and shoulders, pearly and round, with top slightly flattened, about the size of small rape seeds, odour of patient very sour; no pains in bones; no swelling of joints; complains of great weakness. Ordered—℞ Liq. ammon. acet. ℥ss., spirit. æther. nit. ℥ij., tinct. cinch. ℥ss., infus. cinch. ad ℥viij. An ounce three times daily.

15th.—Deafness less, sweating still continues, cough much better, urine still heavy. Pulse 100, soft, temperature 99·3°, very weak; ordered plenty of chicken broth. Tongue cleaner, but still with a good deal of fur towards root. To continue mixture.

18th.—Pulse 74, temperature 98°, tongue clean; sweating began to lessen last evening; now completely gone. Urine clear, though not much increased in quantity, weakness extreme, can hardly lift his hands off the bed, complains of itching in his skin, the epidermis is coming off in fine scales. From this day he rapidly improved, and was soon able to get up, but even now complains of weakness, and says he is not quite the man he was before "it took him."

Case II.—J.W., æt. 56, a labourer, of powerful build, and much younger than his looks, sent for me on the 14th of October last. He complained of the following symptoms, having been ill some four days:—

Pain in the right side, cough and difficulty of breathing. He stated that four days before he had been working in the field, when he was taken with a shivering and vomited. He then went home and went to bed, taking, by the advice of an old woman, a tumbler of punch. Next morning he was in a profuse sweat, and had continued so until he sent for me. On examination I found evidences of congestion of his right lung. His pulse was 120, quick and soft, his temperature 102°; his urine was very scanty, and high coloured, bowels confined, profuse sweating, and miliary vesicles over chest and shoulders, expectoration green, and tinged with blood. Ordered—℞ Calomel grs. xij., pulv. opii gr. iss., pulv. ipec. grs. xviij. Ft. pulves, vi. One three times a day. A blister under right shoulder-blade for five hours, to be followed by a light linseed poultice; also, a clyster composed of decoction of barley, turpentine, as he complained of flatulence, and castor-oil.

15th.—Rather better, but lung complication, if not worse, not much better; *sweating stopped.*

16th.—Very bad, tremulous delirium, temperature 96°, pulse very quick, scarcely countable, respiration sobbing; face pale, pinched, and with that peculiar look by which

every practitioner knows so well that Death has set his seal on the patient.

17th.—Death.

I was for some time puzzled to account for the cause of the retrocession of the sweating and consequent great aggravation of symptoms resulting in death, until I heard from a neighbour of the deceased that he expressed a wish to have his bed made, and they put him standing on the mud floor until the bed was settled, which took some considerable time, and that when getting in again he complained of shivering, and soon after of great dyspnœa, and never rallied. I need scarcely state I heard nothing of this from the friends of the patient; they knew they had acted contrary to my orders; the Irish peasant, when in the wrong, knows how to cover his mistake in a very specious manner.

I think the cases mentioned suggest the following method of treatment:

1st. To encourage the sweating, as the sudden check of the perspiration was so evidently in this case followed by aggravated symptoms and death.

2nd. To look carefully for chest complications, as in both of the cases now recorded they predominated.

3rd. To support the strength in persons advanced in years, as they so early complain of great weakness.

That it was miliary fever, in contradistinction to relapsing fever, I think may be fairly urged by the following circumstances:—

1st. The similarity in the favourable and fatal cases of the symptoms, and the fact that lung complications were predominant in both.

2nd. The fact that the sweat was equal both *by day and night*, and not as in relapsing fever, chiefly by night.

3rd. That in the favourable case there was no relapse.

4th. That the patients were both men of comfortable means in their station of life.

5th. That there were no petechiæ.

6th. That the miliary petechiæ appeared on the third or fourth day instead of at the crisis as they appeared in the famine fever.

7th. That the first symptom of recovery was cessation of the perspiration, whereas famine fever generally showed an amelioration by profuse sweating.

CASE OF EMPHYSEMA OF LUNG WITH HEART DISEASE. (a)

By Christopher I. Nixon, L.R.C.S.I.,
Physician to the Mater Misericordiæ Hospital, Dublin.

Dr. Nixon showed specimens taken from the body of a man aged twenty-two years, who had been a patient of the Mater Misericordiæ Hospital. On admission he had evidences of general venous congestion. The cause of the embarrassment of breathing was capillary bronchitis supervening on old emphysematous lungs. He had the barrel-shaped chest usually seen in cases of capillary bronchitis. The heart was displaced downwards, and there was a very well-marked embolous beat felt in the epigastrium. For some hours before death the patient had well marked Cheyne-Stokes' breathing. The period of apnœa was not well marked in this case. On post-mortem examination the lungs presented an unusually good example of emphysema. The lungs were very voluminous, and protruded through an opening in the sternum. The condition of the heart was interesting. On examining it posteriorly they found that at the right auricle there were some evidences of lymph which were better marked when the heart was first removed. The effusion of lymph was solely confined to the back part of the right auricle. The apex of the heart was formed entirely by the right ventricle. The heart presented a very curious form; it was not exactly square-shaped, but had that form which was distinctive of great distension of the right side of the heart. The valves were healthy, and there was no enlargement. The right side was enormously distended, and the walls of the right ventricle were extremely hypertrophied. On looking through the tricuspid orifice the dimensions of it were seen to be very large, and it admitted with ease the tips of the five fingers. The valves were quite incompetent to close up. The chief point of interest was the occurrence of a loud murmur in the dynamic region at the right side of the heart, and he thought the explanation he offered of that a reasonable one, that when they had a murmur developed to a degree of intensity, the walls of the ventricle had undergone considerable hypertrophy. He thought that fact had been alluded to by Dr. Hayden in his work on Diseases of the Heart. Another point of interest was the occurrence of Cheyne-Stokes' breathing in a case in which there was no disease whatever of the aorta—in fact, if anything, the aorta seemed narrow. As far as he could see, the case went to support Dr. Little's views as to ascending and descending breathing. Another point of interest was the absence of double pulsation of the external jugular veins.

(a) Read before the Dublin Pathological Society.

INTUSSUSCEPTION IN A DOG. (a)

By Arthur Wynne Foot, M.D.,
Physician to the Meath Hospital.

Dr. A. W. Foot exhibited a specimen taken from one of the lower animals—from a large Mount St. Bernard dog. It was an example of intussusception at the termination of the ilium and ilio-cæcal valve with the cæcum in the ascending colon. The animal had been convalescent from a severe attack of distemper, and got within reach of a large round of spiced beef, the entire of which he greedily ate. The immediate result was an attack of jaundice. Medical aid was called in, and the doctor who saw the animal prescribed a mixture of aloes, scammony, and jalap. The animal had but a small evacuation from the bowels, and then exhibited great tenesmus, with a discharge of blood, and great efforts at straining. The dose was repeated, and the symptoms were aggravated thereby, and at the expiration of three days the animal died. Before death he had become completely jaundiced, and exhibited the jaundice at his eyes, under the nails, and at the mucous membrane of the gums. There was but little peritonitis; and it was a remarkable thing that dogs seemed but little liable to peritonitis, and that was borne out by a case brought before the London Pathological Society, and recorded in last year's Transactions by Mr. Jonathan Hutchinson. The intussusception was very large, the intussuscepted portion of the gut being about twelve or fourteen inches in length.

Clinical Records.

MELBOURNE HOSPITAL. (b)

A Case of Embolism treated by the Intra-venous Injection of Ammonia.

Under the care of T. N. Fitzgerald, L.R.C.S.I.

I was called, in consultation with my friend Dr. Rees, to see a gentleman aged 68, of medium height, full habit, and florid appearance. He complained of pain about the region of the bladder, frequent micturition; passed large quantities of pus and mucus with the urine, and had, in fact, all the symptoms of stone. We examined his bladder carefully, and found what we considered a sacculated calculus. He had been sounded previously on several occasions by surgeons, but the stone was not discovered. As lithotrity in such a case was contra-indicated, we decided on lithotomy.

Accordingly, on the 1st of June, the patient being placed under chloroform by Dr. Neild, and the staff being held by Dr. Rees, I proceeded to perform the lateral operation. As the perinæum was very deep and the prostate enormously enlarged, the bladder could not be reached by the finger. However, after a little difficulty, I succeeded in extracting the stone (which was in a saccule in the left wall of the bladder) by a long curved forceps. It was of uric acid formation, covered with earthy phosphates. It must have been firmly attached to its nidus, as a large portion of thickened membrane came away closely adherent to one side of the stone.

(a) Read before the Dublin Pathological Society.
(b) Read before the Medical Society of Victoria.

There was a little troublesome hæmorrhage from the prostatic veins, which was stopped by the umbrella catheter.

The case progresed favourably until the fifth day, when sitting up in bed, with the window open, he caught a little cold. On the evening of the same day Dr. Rees saw him. He found the temperature 102°; the pulse 120 ; the respiration hurried. Fearing the advent of some pulmonary complication, he ordered turpentine fomentations and a mixture containing carbonate of amonia and ether. On the following morning, the feverish symptoms had subsided very much, but acute orchitis of the right side suddenly appeared. Leeches and hot fomentations were ordered, which by the the evening had had the effecl of reducing the inflammation and removing the pain. Late on the evening of the same day, June 8th, Dr. Rees saw him again, and noticed a further increase of temperature, and feverish symptoms ; but the testicle had resumed its natural size, and was not painful. Early on the following morning I was summoned, but could not attend until half-past 9 a.m. On entering the chamber, I found a wonderful change from the previous day. The man was lying on his back ; chest spasmodically heaving ; no pulse to be felt at the wrist ; the heart could be heard, and it only produced a sort of irregular churning noise ; the whole body was deathly cold with the exception of the feet and legs, which perhaps were kept warm by the hot-water jars in the bed. The attendant, who was a very intelligent man, informed me that at a quarter-past 6 a.m. the patient was sitting up in bed washing, and expressed himself as feelihg much better, in fact he wanted to get up, so that he (the attendant) left the bedroom for about five minutes, and on his return found the wondrous change that I have described. I told the friends that tha case was hopeless, and expressed an opinion that the man would be dead in a few hours. Having considered, however, the case for a few moments, I viewed it as one of embolism of some large vessel, and as a *deraier ressort* I determined on trying the intra-venous injection of ammonia. The largest vain visible at the bend of the elbow (the median cephalic) was laid bare and an injection of ten drops of liquor ammoniæ fort. with the same quantity of hot water quickly sent into the circulation. A few convulsive movements followed, chiefly of the facial and cervical muscles. There was at once a decided change for the better in the pulse, it did not last long, as in ten or fifteen minutes the old symptoms of intense prostration retbrned. Again ammonia, with tha hot water, was sent into the same vein. The result was just as before, except that the arm joined in the convuisive movements, and that there was a more lasting effect on the circulation. Being obliged to leave at half-past eleven, I left instructions for the administration of brandy and beef-tea injections into the bowel, hot applications to the extremities, and the ordinary treatment in such extreme cases. Dr. Rees saw the case about one o'clock and injected ammonia as before, and with the same result. By this time the pulse could be counted, but it was extremely weak, compressible, and irregular. We agreed te meet in the evening in consultation, and should the patient be then alive to try the ammonia in a larger quantity. Accordingly, we met at about seven o'clock. The man was then alive, breathing still irregularly, the iace was duskish, the pulse very weak, and the skin cold and clammy. We opened a vein in the left arm at the bend of the elbowf and injected with a jerk fifteen minims of liq. ammoniæ fort. and the same quantity of boiling water. This was at once followed by a violent epileptiform convulsion, which lasted several seconds. Gradually, like a man recovering from a fit, he opened his eyes, looked round, asked what was the matter, and wantod te engage in ordinary conversation. The change was really magical. The pulse at the wrist returned to its natural and full force ; the discolouration of the face disappeared as soon as the surface of the body resumed its proper temperature. From that day to the present, the case has progressed satisfactorily, and the man is now quite out of danger. The question is, what was the nature of the case? and on this point I should very much like to hear the opinion ol this Society. Both Dr. Rees and myself at first viewed it as one of embolism ; I am still of the same opinion, although the situation of the the clot is a matter for speculatiou. Was it in the right auricle? if so, was it dissolved by the ammonia, or washed into the circulation? We watched the case very closely for abscess, or any other symptom indicative of the breaking down of a clot, but the only change worth noticing was slight congestion of the basis of the lungs (which we viewed as hypostatic) and a mild bronchial attack. In a recent number of the *Lancet*, Dr. Richardson relates the result of his researches on the effect of ammonia (given in very large doses) on clots. If it is a fact that ammonia given by the mouth has the power of dissolving a coagulum, surely the intra-venous injection of its most powerful preparation ought to have as good if not a better effect. I am quite convinced that this man's life was saved by the ammonia, and I feel that we all owe a great debt to Professor Halford for introducing this treatment.

The operation itself requires to be carefully done. It is not an uncommon thing to hear of a slough being produced from the extravasation into the tissues of a portion of the powerful caustic alkali. The first case I operated on, although only a drop or two of ammonia escaped into the tissues, a slough the size of a shilling was the result, and the separation of the dead flesh and healing of the wound took a long time. Being warned by this case, I have been very careful ever since, and such a result hae not taken place.

Transactions of Societies.

PATHOLOGICAL SOCIETY.

Dr. Nixon showed several specimens, the description of which will be found on page 278.

Dr. A. W. Foot exhibited a specimen, description of which will be found on page 278.

Dr. James Little exhibited a specimen which tended to show that enteric fever began with great abruptness. It was taken from the body of a young woman who was admitted to hospital with sore-throat, vomiting, &c., and died on the eighth day of her illness. They could get very little history of the case indeed. The symptoms which usually present themselves were exhibited in the case before admission to hospital. As her husband was out at work she had been left in a room by herself, and when admitted was unable to move a finger. She lay covered up in the bed perfectly prostrate. She was unable to speak or put out her tongue, but readily swallowed any liquid given her. A quantity of dark brown, exceedingly offensive feculent matter was being continually squirted from the bowel, so much so that the woman was, in spite of every care, continually lying in a state of wet. She also discharged urine in that way, and on adopting the precaution of examining the region over the bladder, he noticed that it was full, and on a catheter being introduced, fifty ounces of high-coloured and slightly albuminous urine escaped. The woman never rallied from that condition, and died on the third day after her admission. The intestines presented most characteristically and in an aggravated form the appearances seen in cases of enteric fever. The last eight feet of the small intestine and the first two feet of the large intestine presented marked appearances in the solitary glands. The solitary glands, when first removed, were very like those which were seen in the skin in a case of small-pox when the eruption was becoming pustular. Peyer's patches were very much affected ; those in proximity to the ilio-cæcal valve were chiefly affected. There was no eruption, and the temperature presented nothing that was very characteristic.

Medico-Parliamentary Intelligence.

THE OBSTETRIC LICENCE OF THE ROYAL COLLEGE OF SURGEONS.

Dr. Lyon Playfair has given notice of his intention to ask the Vice-President of the Council, whether he is aware that the Royal College of Surgeons possess by charter and now exercise powers to grant a licence which entitle the holders to a place on the Medical Register, and to all the privileges of fully qualified medical practitioners, although the licentiates may not have been subjected to examinatian in anatomy, physiology, medicine, or surgery, but simply in the single subject of midwifery ; and whether he has communicated with the Medical Council on the subject.

CORONERS IN IRELAND.

Sir M. Hicks-Beach said, in reply to Mr. O'Shaughnessy that last session he stated to the house that, in his opinion

t was advisable that an inquiry by a select committee should precede any general legislation on the office of coroner in Ireland, and he had expected that some hon. member who took an interest in the question would this year take some action with regard to it. As the subject was not of a pressing nature, it was not the intention of the Government to move for the appointment of a select committee.

ARMY MEDICAL OFFICERS.

Mr. HARDY, replying to Mr. Dunbar, said every application for exchange made by medical officers of the ar my was carefully considered and decided on its own merits. He did not intend to make any change in the existing system.

VIVISECTION.

Mr. CROSS said, in reply to Mr. Wait, that the Government did not in any way underrate either the importance of the evidence given before the Royal Commission on vivisection, or the clear manner in which the commission had gene into and reported upon the question. At present, however, he regretted to say he could do no more than give the hon. member an assurance that the subject would receive the careful consideration of the Government. He could not state whether any immediate legislation would be proposed or not.

VACCINATION.

Mr. SCLATER-BOOTH, in reply to Mr. Pease, said his attention had been directed by his hon. friend's question to the case of Mr. Milner, the Chairman 6f the Keighley Board of Guardians, who had been committed for ten days' hard labour for the non-payment of a fine of ten shillings for the non-vaccination of a child. No one regretted more than he did the necessity for prosecutions under the Vaccination Acts, especially when they were repeated a number of times. As, however, his hon. friend quoted the case of a chairman of a board of guardians, he might remark that it was the duty of a person filling such a position to see that the law was enforced, and not to set an example of disobedience to it. Moroover, the payment of the fine would at once release Mr. Milner from prison. It was not his intention to propose to the Government any alteration of the law; and even if an alteration in the Vaccination Acts were proposed, Parliament would probably not consent to it.

ARMY MEDICAL SCHOOL.

Mr. G. HARDY, in reply to a question by Mr. O'Leary, said it was not intended to fill up the vacant professorship in the Army Medical School. The question of the Army Medical School would be submitted to the senate under the new act, and until he had heard what they proposed, it was not proposed to fill up the professorship now vacant.

ANOTHER appeal is made for funds towards the Harvey Statue to be erected at Folkestone. £800 only of the £3000 required has been subscribed.

A MARBLE bust has just been placed in the museum at the Middlesex Hospital of Mr. Campbell de Morgan, senior surgeon. The bust was executed by Mr. J. G. Lough, by whom it was presented to the hospital as "a token of gratitude and affection" to the subject of it.

A NEW scientific periodical entitled *Electricité* has been issued in Paris, under the patronage of Count Halley d'Arroz, director of the International Exhibition of 1877. It will be profusely illustrated, and will be used by the Commission of Organisation as one of its official organs.

THE first general geological map of Australia is now published. The name of Mr. R. Brough Smyth, F.G.S., appears alone on the title, but it has, of course, been largely compiled from the reports of other Australian travellers and investigators, among whom may be mentioned the names of Daintree, Selwyn, and the Rev. W. B. Clarke.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, APRIL 5, 1876.

WATER SUPPLY OF LONDON.

A NUMEROUSLY attended deputation from the "National Health Society" waited on the Home Secretary on Tuesday last, for the purpose of presenting a memorial on the deteriorated water-supply of London.

The deputation was introduced by the Right Hon. Dr. Lyon Playfair, M.P., and Dr. Humphry Sandwith, C.B., presented a memorial which complained that the water supply was horribly tainted with the sewage of a district estimated at nearly 100,000 persons, and exclusive of a vast floating population, constantly occupied on and about the intake of most of our water companies.

The sixth report of the Rivers' Pollution Commission stated that vast experiments, unconsciously tried upon the health and lives of large populations, had resulted in proving conclusively, and at the cost of thousands of lives, that the water companies had transmitted cholera to their customers, and the deputation endorsed the words of the commissioners, who said, "It is much to be desired that even the claims of invested capital may not in future be allowed to impose upon the population of this country any further tests of so cruel and disastrous a character." It was a fallacy to say that the impurities were chemically changed and destroyed during their course down the river by the operations of Nature, and no sort of filtration would avail against water polluted in the manner referred to. The most costly domestic filters were useless against certain loathsome impurities, and even if effective could not be used by the mass of the population, and ought not to be required. The memorial further alluded to the evile produced by the want of a constant service supply at high pressure, and pointed out that the health of the poor is injured by water being stored in filthy cisterns, and absorbing the air of crowded dwellings. The deputation believed that the only means of carrying out a system of constant delivery of pure water is to place the water service under public control, and they requested the Home Secretary to take measures for transferring the direct control of the water supply

of London to a public body representative of the ratepayers, such as the Metropolitan Board of Works or a municipal council.

Cardinal Manning pointed out that the inefficient and impure supply of water might have a very evil effect upon not only the health but the sobriety of the poorer classes, and he thought it would be good public policy to follow the example of such places as Glasgow, Manchester, Leeds, and other towns, in the transfer of the supply to the local authorities; while Dr. Lyon Playfair thought that the Thames might still afford a proper supply if led away to its destination before it is mixed with the sewage of Oxford, Reading, and other large towns, and before it is fouled by the filthy discharges of paper mills, and other disgusting refuse. By the Rivers Commissioners of 1868 we are told that an exhaustive examination of the water of the Thames on the one hand, and of spring and deep well-water on the other, proves beyond a doubt the immense superiority of the latter for dietetic purposes. Indeed, it is obvious that with the most efficient river conservancy imaginable, aided by efforts of the Legislature, the Thames must always receive as much pollution as to render its use for the supply of the metropolis highly objectionable.

The Home Secretary said that he agreed so far with the objects of the deputation because the importance of the question could not be overrated. The supply of pure water to a population equal to the whole of Scotland was a matter of the greatest possible importance to the health and welfare of this great community. The question of the drinking water in London was one which had been a long time in his mind; ever since he had been in office he had been in consultation with persons who had considered the matter very much, and he had had some able papers laid before him with regard to the best means of obtaining a good water supply. At the same time, he was bound to say that he had not thought it right to lay his views before the Government, because he considered it would be wrong in any Minister to do so until he could show that he had made up his mind as to the practicability of carrying out such views. Until he (Mr. Cross) made up his mind on the subject, he should not lay any scheme before Government. He could promise that, if he lived, and remained in office, the matter would receive the attention of the Government.

PHYSICAL TRAINING FOR THE ARMY.

We have noticed that our excellent contemporary the *Globe* has on several occasions drawn attention to the necessity of adopting some means for improving the *physique* of our soldiers. The subject is certainly of grave importance, both in a political and in a hygienic point of view, and we are rather surprised that the Medical Press has not used its influence to encourage a movement that would be attended by most beneficial results. Still more surprising is the indifference with which the Government and the War Office authorities have regarded the physical training of our troops. There are indeed strong grounds why some change should be made in the manner in which our soldiers have been hitherto allowed to spend their time. There is an impression among our most experienced officers that the average *physique* of the men by whom the army is now recruited is far inferior to what it formerly was. It is not within our province to enter into the political reasons why in a small standing army like ours every soldier should be not only of average health, but also physically strong, active, capable of undergoing great fatigue, undertaking long marches—showing, in fact, good "staying" powers, but these desiderata once admitted, we feel it our duty to point out how much may be accomplished by devoting a little more attention to the physical education of our recruits. In fact, when we reflect what was done in this direction in the case of the best disciplined army the world has ever witnessed—namely, that of the Roman Empire—we are at a loss to account for our apathy and neglect. Every one who has read the opening chapter of Gibbon's great work must recollect what importance the historian attached to the physical training of the Roman legions as a condition of the wonderful efficiency to which they attained. The Roman exercises, he remarks, "comprehended whatever could add strength to the body, activity to the limbs, or grace to the motions. The soldiers were diligently instructed to march, to run, to leap, to swim, to carry heavy burdens. . . . It was the policy of the ablest generals, and even of the emperors themselves, to encourage these military studies by their presence and example; and we are informed that Hadrian, as well as Trajan, frequently condescended to instruct the inexperienced soldiers, to reward the diligent, and sometimes to dispute with them the prize of superior strength or dexterity." How different is the picture that would faithfully represent the habits and education of our soldiers! What a contrast would those stalwart and broad-shouldered Romans present to the many puny, sallow-faced, and narrow-chested men with whom our army is recruited—to men who "fall out of the ranks when tested by a long march or rather fatiguing field-day"—to men who cannot keep up a "double" for a quarter of a mile at a stretch, and who often fail to walk twenty miles in a day.

We are quite aware we may be met with the plea that the mode of modern warfare has rendered physical training of far less consequence now than it was at a time when a battle was generally a matter of close combating and hand-to-hand fighting, and when strength of muscle often decided the fortunes of the day. But this is no reason why physical exercises should be so much neglected by our military authorities as they are, and as they always have been. Forced marches, prolonged exposure to cold and wet, and other circumstances which tax the powers of the constitution, will always be contingencies to be provided against by a well-organised army, and the recent extraordinary feats of Captain Webb and Mr. Weston show what the human body may accomplish when long inured to unusual exertion. Besides, regular and systematic exercise has not only the effect of enabling the body to perform great feats of strength and to undergo extraordinary fatigue: it does a great deal more. It improves the general *physique* of a man who had been previously remarkable for his want of energy and strength. It often removes any inherent predisposition to disease that may be lurking in the system, and what is of equal im-

portance in a military point of view, it enables the system to resist those causes of disease to which every soldier is exposed during an arduous campaign. Nor are the good effects of physical training confined to the body alone. Systematic exercises, especially when practised in the open air, have a most beneficial influence on the mind. They raise the spirits—they invigorate our mental energies—they elevate and humanise our thoughts—they help to banish from the mind all feelings of despondency and many evil propensities, and they enable us to do with alacrity, or to endure with patience, what would otherwise be borne with impatience or resentment. Indeed we do not hesitate to say that there would not be half the crime, half the misery, half the insanity, which is now, alas! so prevalent, if we only realised the advantages to be derived from physical exercise and training, and from those habits of temperance and hygienic practices which all such training necessarily involves.

If therefore we may expect so much from a cultivation of the physical powers of the body, we cannot over-estimate its importance in respect to a small, compact army like ours, especially at a time when there appears to be a great falling off of strong and healthy recruits.

With respect, however, to the best means of carrying out the end in view, there is much difference of opinion. This is, of course, a matter for the consideration of our military authorities; but we must remark that no system will be satisfactory which does not embrace within its influence every private in the line. It has been suggested to organise a system of athletic competitions, to institute both company and regimental contests, supplemented by Government prizes. But the insufficiency of this plan, as well as of the short course of gymnastic instruction adopted in some quarters, consists in this, that such means tend to encourage a high standard of *physique* among a few, while the physical capacity of a large majority of our soldiers would still remain far below that which it ought to be. No plan can secure the object aimed at that does not, during several months of the year, set apart a small portion of each day for athletic exercises in which every soldier would be compelled to take a part. We are, however, trespassing upon the province of other writers. For the present we must be satisfied with endorsing the views of the one or two newspapers which have already drawn attention to the subject, and we trust that the whole press, both lay and medical, will continue to agitate a question in which, from feelings of patriotism alone, we should all feel deeply interested.

CONVALESCENT HOMES.

Mrs. Gladstone's Convalescent Home at Woodford, which has tended so much to the relief of particular hospitals and the benefit of convalescent patients, had its origin in the outbreak of cholera in 1866. Since its establishment other institutions, having similar objects in view, have been set on foot, not one of which, however, has been more earnestly devoted to the relief of the afflicted poor than the Convalescent Home for East London. The Lord Mayor of London evinced much interest in the movement by throwing open the Mansion House to a crowded and influential meeting of its supporters on Tuesday last; for it is acknowledged that a necessity for Convalescent Homes exists, and deserves the hearty co-operation of the benevolent.

Mr. Gladstone, on being called upon to speak, first begged to tender the cordial thanks of Mrs. Gladstone and himself to the Lord Mayor for the personal influence he had brought to bear in furtherance of what he felt to be a benevolent and worthy purpose; then proceeded to move the following resolution:—"That, to render convalescent homes available to the poorer classes, the system of privileged tickets, entailing canvassing and delay, should be dispensed with;" and he went on to say: "He belonged to that section of the community, who believe that the system of election for charities, with the extensive operations it entails, is a most ingeniously contrived machine for intercepting on their way to other benevolent ends a large portion of the alms of the community." These observations were received with cheers, for it has become more apparent of late that a grievous wrong must be done, more particularly with regard to convalescent homes, if applicants are compelled to exhaust their strength and means in a vain endeavour to obtain letters of admission to their benefits; and we believe, with Mr. Gladstone, that it is both wise and prudent that admission to hospitals, and indeed all institutions established for the afflicted classes, should be according to the urgency and need, and perfectly free—free in this way, that every man should be able for himself to put forward his claims to the benefit of the institution, and that there should be no competition as to coming within its doors but the competition of the greatest merit, that is to say, of the greatest need. The management of Mrs. Gladstone's Home may be taken as a model worthy of imitation, for this does not exceed five per cent. on the expenditure and work done. By a careful and rigid economy in every particular, nearly the whole of the money subscribed went to the support and benefit of those for whom it is intended. This, however, could scarcely be effected unless Mrs. Gladstone and those who so cordially assist in her good work gave their services almost gratuitously. But very few of the homes of the London poor are in any way likely to promote the recovery of the convalescent patient when discharged from the hospital, and we therefore hope that the result of Tuesday's meeting will tend not only to benefit Mrs. Gladstone's Home, but will also serve to largely extend the excellent system of Convalescent Homes throughout the country.

Notes on Current Topics.

Death from Chloroform.

An inquest was held at Liverpool on March 28th respecting the death of a Mrs. Rowlinson, who died while under the influence of chloroform. Mr. Evan Abraham Morgan said he was a duly-qualified physician and surgeon, practising as a dental surgeon. The deceased came to his surgery and told him she wished some stumps removed, and expressed a desire to have chloroform. He examined her pulse and heart, and thinking her a fit sub-

ject, gave her chloroform slowly. While she slept he took out two teeth and three stumps, at the same time keeping her face and breathing in view. Seeing a sudden change come over her, he opened the window and then threw cold water in her face. Her breathing became slower, and he placed her on the floor, and she then ceased to breathe. He resorted to Hall's system of artificial respiration, which, however, did not answer; and next tried Sylvester's method, and she breathed freely for about two minutes. Meanwhile, he had sent for Dr. Banks. The breathing of the deceased suddenly ceased altogether. Dr. Banks, when he came, applied the galvanic apparatus, but in vain. Dr. Richard Caton, lecturer at the Liverpool School of Medicine, who with Dr. Banks made a post-mortem examination of the body, said the cause of death, in all probability, was arrest of the heart's action, attributable partly to the weakened condition of the heart from disease, chloroform being the exciting cause. The jury gave a verdict to the effect that Mrs. Rowlinson's death arose from misadventure—from the administration of chloroform for a dental operation, and they absolved Dr. Morgan from all blame.

We cannot dissent from the view which the jury took in this case, and we admit that in the administration of dangerous anæsthetics by proper hands and with due care a misfortune cannot justly be visited upon the operator; but we consider that the administrator is imperatively bound to inform the patient or his friends of the risk which is incurred. The fact is now established that the mortality from chloroform is as high as 1 in less than 3,000 cases; and this in spite of the employment of the most approved methods of administration, in spite of the absence of appreciable organic disease in many of the victims, and in spite of the best known means of combating deadly symptoms when they show themselves. Even were no safer anæsthetic available, it is doubtful whether patients would consent to inhale chloroform for trivial operations like tooth extraction if they clearly understood the danger which they ran. On this latter point we may merely add that the majority of practitioners who devote themselves to the administration of anæsthetics have now entirely abandoned the use of chloroform in favour of nitrous oxide gas in dental operations, and most of them employ, in the majority of cases, the gas followed by ether in general surgery. It appears desirable that this change of practice, which is based upon sufficient scientific evidence, should obtain a wider publicity than it appears yet to have achieved.

Dress Reform.

A RECENT number of the *Housekeeper* has rather a long paper on this subject, and although some of the statements therein made are somewhat exaggerated, the following extract will show that there is a good deal of truth in the remarks of that journal. "Fashionable attire," observes our contemporary, "separates the body into zones. The upper part of the chest and the feet and ankles are the frigid zones, while the lower part of the abdomen is a torrid zone. . . . Instead of supplying the required extra clothing of these parts (feet and chest), fashion totally ignores the wants of nature, and gives the limbs even less protection than other parts which need it less. The upper part of the chest is often exposed even to the eye; at best it is usually covered by only a few thin layers." The writer then shows how the abdomen and thighs of females are, on the other hand, overburdened with clothes, and remarks that, while the "central portion of the body is thus burning with excessive heat, the limbs are allowed to go almost nude!' Among other remarks it is stated that "the many heavy skirts and under garments which are hung about the waist, with no support from above, drag down the internal organs of the abdomen, and cause them to press heavily upon the pelvis. After a time the slender ligaments which hold those organs in their place, give way, and various kinds of displacement and other derangements occur."

We feel sure our readers will readily endorse these observations; in fact, we doubt whether we are not ourselves very much to blame in not paying more attention than we do to the dress of our patients, especially of our female patients. We shall not be far wrong in saying that at present our advice in this direction seldom extends further than ordering a little flannel to be worn next the skin. As far as "individual hygiene" is concerned, the manner in which our patients are clothed is a matter of the greatest importance, and as we have long been of opinion that the general practitioner should look upon himself as an "officer of health" to the families who have the benefit of his services, we cannot too strongly recommend him to bear this subject more in mind either when he is actually treating or adopting measures for the prevention of a disease. We cannot now enter fully upon this topic; but with regard to keeping the chest well protected—especially in the case of females, who are so apt to be negligent in this respect—we may incidentally remark that the most recent investigations into the pathology of that chest affection which, of all chest affections, is the most common and the most fatal, show the necessity of protecting the lungs by proper clothing from the influence of cold—sudden changes of temperature, suppression of the perspiration, &c. The majority of the cases of pulmonary consumption have been shown to depend upon changes in the lung of a catarrhal or inflammatory nature, and the exciting cause of the disease to be in most instances due to what in common parlance is called "catching cold."

Dr. Crichton Browne.

OUR readers will perhaps remember some few weeks since we announced that Dr. Crichton Browne, whose name is eminent in the treatment of mental diseases, had received the lucrative appointment of Visitor of Chancery Lunatics. A few days since a memorial was presented to him magnificently illuminated on vellum, and signed by his past colleagues at the West Riding Asylum, and by about two hundred members of the profession principally engaged in asylum practice, in token of their appreciation of his great talents, and of the pleasure his appointment gave them. We have much pleasure in adding our sincere gratulations to those of the memorialists. Government appointments are not always made with a due regard to merit; the present is a happy exception.

Ether Drunkards.

THE registrar of Draperstown, county Londonderry, states in his return for the last quarter of the year 1875 that he had to register a death occasioned by drinking ether, which, he says, has been rather extensively made use of in that locality for many years, notwithstanding great attempts made by the clergy and others of influence in the neighbourhood to stop the practice. The person referred to had been drinking, it was stated, for two or three days, and had not taken food; on the evening of his death he partook of a draught of ether with two companions, and never spoke afterwards.

The College of Physicians of London.

ON Saturday was completed the work of raising into the hitherto vacant niches in the entrance to the College of Physi cians, Trafalgar Square, three statues by Mr. Henry Weekes, R.A., sculptor. Immediately over the doorway is placed that of Linacre, the projector and first President of the College. On one side is the statue of Harvey, by whose generosity the College obtained some landed property; and on the other the statue of Thomas Sydenham.

A Year's Mortality in England.

FEW of our readers would probably care to wade through the mass of tables supplied by the Registrar-General in his annual returns, yet they contain much interesting and valuable information; information as attractive to the statician as a good novel to its devotee. There is not a subject touched upon in this report which is not fraught with intere.t to every medical man. Thus we find births, deaths, and marriages given as they occur in our principal cities and towns, and are enabled to compute their relations to each other and their effects upon the general mortality; the water supply, sewerage, barometrical changes, &c., also occupy their allotted space, and show how they dovetail in with the ultimate result. We find that our largest towns in England are still growing; London proper, for example, contained a population in the middle of the year of three millions four hundred and forty-five thousand one hundred and sixty. The increase over the numbers in the previous year was 44,459, the registered births (122,871) having exceeded the deaths (81,513) by this number, which thus forms the year's balance. Then people flock to London from every county, from every part of the empire, and Londoners by birth flow beyond its limits in great numbers. The extent of this interchange of population is unknown, but the difference in the inflow and outflow probably does not exceed 3,000, that being all of the increase of population that remains unaccounted for by the excess of births over deaths.

During the year the births of males exceeded the births of females by 2,477; and upon the other hand the deaths of males exceeded the deaths of females by 2,321, thus redressing the inequality at birth. It is evident, therefore, that if there is any great inequality in the living popualtion of the two sexes it is due to the movements of migration. Now the females exceeded the males by 220,158. At the census of 1871 of the 1,731,109 women and girls, 226,393 or more than one in eight, were domestics, for whose services there is a demand greater than the demand not only for men servants, but for men in any other occupation. The milliners, dressmakers, sewing machinists, and seamstresses amounted to 102,359, the latter probably being as unhealthy as domestic servants are healthy. The estimated increase of population after the census of 1871 was 190,900, so the density of population then expressed by 42 persons to an acre has risen to 44 persons to an acre.

It has been shown in the supplement to the 35th report that by a general law under the existing sanitary conditions of England the mortality increases with the density of the population, and in such a way as to make the increased rate of mortality equivalent to nearly the eighth root of the increase of density. Now there were 25 persons to an acre in 1841, and 42 persons to an acre in 1871; the mortality in the years 1840-4 was 24·4, and by the increase of density it should have been 26·0 in 1871; but it was on an average 23·5 in the five years, of which 1871 is the middle. So it is a fair inference, that the Health of London instead of getting worse by reason of increased density, has grown better by countervailing sanitary measures.

The mortality in the year was at the rate of 23·7 to 1,000 living, which is higher by 1·2 than in the preceding year, and higher than the average of the preceding five years. The increase was very much due to the combination of epidemics of scarlet fever and whooping-cough. Mensenteric disease also increased. Bronchitis and pneumonia were raised above the average by the weeks of very low temperature. It is worthy of remark that the number of deaths to be dealt with in the year 1840 was 46,281, while in the year 1875 the number was 81,513, both being average years, and this is mainly due to increase of population, for the mortality was at the rate of 25·0 in the first, and 23·7 in the last year. The weekly deaths to be abstracted were 890 in 1840, and 1,568 in 1875.

Next we come to Greater London, which extends over the City and over the Metropolitan Police District, within a radius of 12 miles. The area is 698 square miles, equivalent to that of a circle of 14·9 miles radius.

The population was 3,885,641 in 1871; and it was estimated for 1875, by a satisfactory method, at 4,207,167; the births exceeded the deaths by 51,903; but the increase going on by this and by excess of immigration over emigration together was at the rate of about 80,000 a year. The mean density of population was between 8 and 9 persons to an acre.

We now come to the eighteen large English cities, which, exclusive of course of London, contain an aggregate population of 3,236,873. Nearly all these cities present the same problems for solution as London. Each has in its different degrees its Outer Ring, now healthier than the Inner City of these returns, but more destitute of sewerage, water supply, and cheap light, and thus owing its relative superiority mainly to the lesser density of its population, which is every year increasing. The mortality of some of the cities is decreasing; and among them may be named Liverpool, Manchester, Sheffield, Sunderland, and Newcastle-upon-Tyne. Bristol, Birmingham, Nottingham, Salford, Oldham, Bradford, Hull experienced higher rates of mortality in 1875 than in 1871. The salubrity fluctuates from year to year; but in the year 1875 the

towns, including London, stood in the following order :—Portsmouth 19·5, Sunderland 22·4, London 23·7, Norwich 24·5, Wolverhampton 24·7, Sheffield 24 8, Newcastle-upon-Tyne 26·1, Leeds 26·4, Birmingham 26·5, Leicester 26·6, Bristol 26·8, Bradford 27·1, Hull 27·4, Liverpool 27·5, Nottingham 27·7, Oldham 29 6, Manchester 29·9, and the borough of Salford 31·5.

The fifty other large English towns, with an estimated population of 2,724,784, offer some interesting facts. In this year the mortality was at rates below 20 per 1,000, in Dover (16·4), Chatham, Maidstone, Hastings, Reading, (18·7), Colchester, Devonport (18·5), and Cheltenham (18·8). The mortality exceeded 26 in Exeter, Stockport (31·6), Wigan (30·3), Bolton, Bury, Aston-under-Lyne (33·2), Preston (31·8), Gateshead and Carlisle.

Of course it will be generally understood, that the rates of mortality are chiefly dependent upon the density of population, and it will therefore be inferred that the smaller towns and rural districts, not included in the foregoing, have relatively lower death-rates. This inference is in the main correct; yet London, with its system of drainage and almost perfect sanitation, compares most favourably with districts of much lesser density which are not thus cared for in sanitary matters.

The Mosaic Code and Vitality.

Upon the above subject Dr. Richardson recently delivered a lecture in Whitechapel. Some curious statistics were brought forward. In Prussian Germany still-born children numbered 1 in 97 Jews, 47 Catholics, and 42 Protestants. Half the Jews at Frankfort reached 53 years; half the Christians succumbed at 36. Three reasons had been assigned for the high vitality of the Jews :—1, an innate excess of vital resistance ; 2, the observance of the rules of health laid down in the Pentateuch ; 3, that the Jews have followed, either under the influence of necessity or from natural prompting, a better life in all that relates to the maintenance of a healthy physical existence. There was no physiological or anatomical superiority of the Jews over other races. In some respects they were inferior to Saxons and Celts ; but they had less hereditary tendency to diseases such as scrofula, consumption, and rheumatism. Coming to the second cause, the influence of the Mosaic sanitary code could scarcely be overrated, and its provisions formed a marvellous collection of sanitary rules. The Second Commandment specified the times (the third and fourth generation) required to wipe out the effect of physical degradation. The third, sixth, seventh, eight, ninth, and tenth, all had reference to the rule of the passions. The fifth takes special care of the aged and infirm, and the fourth, which enjoins a special day of rest, and was seven times repeated, is so important a provision for health that a nation which followed it strictly, might, on the purest physiological grounds, expect to realise an extra seventh term of existence.

A great advantage was doubtless gained in the early ages by abstaining from the flesh of animals which fed on garbage, and at the present time those who strictly adhere to the principles of their religion refuse to touch food which may by any possibility be diseased or decomposed; whilst such food is freely partaken of, or even sought for on account of its cheapness, by the lower class of other persuasions. On this score alone a large number of young Jews who would otherwise succumb to diarrhœa and its effects live to swell the number of those who live beyond the fiftieth year.

Among the causes of the third category Dr. Richardson mentioned the comparative immunity from hard physical labour. He referred also to their ablutions and habits of cleanliness entailed upon them by their religion. On this text he might have given them a very excellent sermon, for in the matter of cleanliness the lowest classes of Jews are little if any better than their neighbours. That a far greater comparative number of Jews reach the age of 70 years than of Christians is an established fact ; but after that age it appears that the mortality amongst the Jews is greater than among a corresponding number of Christians. If asked to give the three chief causes of their longevity, we should say—1, abstinence from decomposing food ; 2, abstinence from alcohol ; 3, freedom from syphilis. Why the Jews abstain from alcohol we will not say, but as a fact they do so almost entirely. Syphilis again is extremely uncommon among the Jews. It may be due to the fact, that they have but little communication with others, and it may be in part due to the absence of the prepuce, the loose mucous membrane of which readily receives the virus. The freedom from syphilis would in great part account for the rarity of abortions and of still-born children.

Netley Appointments.

However divided opinion may be on the Army Medical School question, no one can cavil with the opinion very generally held among army medical officers, that the appointments should only be made for a fixed period, and not renewed in the person of the same individual time after time. This is unfair to other officers, who can under such circumstances have no incentive for work. A three years' tenure would, we think, be ample to compensate any officer for the work done. Under such a system there would be constantly flowing throughout the service a number of specially trained men, whose knowledge acquired by careful study could not be but beneficial to the army at large. The disadvantages of such prolongations are very great. They discourage officers having special tastes and capabilities from cultivating these gifts, they minimise the number of officers acquainted with such special details, and in other ways act detrimentally. No greater benefit could scarcely be rendered under such circumstances than the establishment of a fixed and printed rule prohibiting under any circumstances the prolongation of the period of holding those appointments, or if this is impracticable, from class interests, turn them over altogether to pure civilians specially qualified. Anything would be better than the constant grumbling we hear on all sides.

Army Medical Selections.

The appointment of Dr. Charles Gordon, C.B., to the post of Honorary Physician to her Majesty, and of Dr. Bourke, late Surgeon-Major 3rd Buffs, as the recipient of the good service pension recently vacated by the death of Sir David Dominick will, we are assured, be received with satis-

faction by the officers of this Department. Dr. Gordon has contributed a great deal to the literature of his profession in the army, and is one of its most distinguished Surgeons-General, and has very justly earned one of the very few distinctions which the Director-General has at his disposal; we only wish there were more of them to stimulate the flagging energies of the medical officers, for unhappily there are very few indeed who are content to advance the study of military medicine with only the prospect of a barren reward.

Small-pox in Liverpool.

At the meeting of the West Derby Guardians a letter was read stating that there had been a sudden push upon the Liverpool workhouse for accommodation for small-pox cases, the men's wards being full on Saturday, and asking in case of emergency that patients of that class might be received elsewhere.

Prescribing Chemists.

Another instance of the danger to which the public are exposed by this illegal practice was adduced at an inquest held at the East End of London on Saturday last, on the body of an infant aged seven months. It was alleged that death was occasioned by the administration of an improper mixture prescribed ond prepared by the wife of a chemist. Dr. Harris, who was called in, said the deceased was dangerously ill, and he ordered a warm bath. The same evening the infant went into convulsions and expired. Dr. Carpenter, who was also called in, said he had examined the mixture prescribed by the woman. It contained rhubarb, the administration of which in such a case as that under consideration would accelerate death. The evi. dence not being complete, the magisterial decision was deferred until one day this week. Here we observe the practice we have so often deprecated has gone a step lower. A chemist like other men cannot avoid being absent occasionally, but in order not to lose custom, his wife becomes the self-constituted doctor, and the not unnatural but very sad sequel follows.

The Vacant Seats on the Medical Council.

The selection of Professor Lister, of Edinburgh, to succeed Dr. Warburton Begbie as the Crown Representative for Scotland, is universally approved by the profession, inasmuch as he is a man not only of high surgical reputation, but of discretion and judgment. The seat vacated by Dr. Parkes is not yet filled, and it is said that a general practitioner will be placed in it in order—to some extent—to meet the views of the Direct Representation party, who complain—and with reason—that the rank and file of the profession is inadequately embodied in the Council. We are gratified that the Crown has placed a pure surgeon in the place of Dr. Begbie, and that the extent of the representation of surgery in the Council has not been reduced, and we hope we may interpret the appointment to signify an intention on the part of the Crown to equalise in some degree the number of the representatives of surgery and of physic.

The Meeting of the Medical Council.

The *British Medical Journal* gives expression, in its last issue, to a hearty concurrence in our view as to the propriety of a meeting of the Medical Council while there is yet time to discuss medical affairs concurrently with their legislative treatment. The *British Medical Journal* says :—

"Our contemporery the Medical Press, which is generally both well informed and judicious in its comments on the General Council, recurs again with great force and truth to the necessity for an earlier date of meeting of the General Medical Council. We have more than once pointed out that the late date of these meetings goes far to nullify the legislative influence of the Council. It meets at the fag end of the session, when all legislation affecting medical interests is either practically accomplished or practically hopeless. Meantime the President of the Council, who is very imperfectly authorised, has to carry on the business of the Council. . . . . The Council ought certainly to meet in April, if its meeting this year is to be anything more than a waste of valuable time and a large sum of money."

Our contemporary in its last words hits the mark. If the Council does not assemble until all the work is done or left undone, there would certainly be nothing lost by its deferring its meeting until the next Christmas holidays, when it might honestly and earnestly devote its attention to those subjects, including the Conjoint Examination question, the Amendment of the Medical Act, the Direct Representation of the Profession on the Council, and other equally important questions which need Parliamentary interference. What will any one gain, except the councillors, by a summer pic-nic of the Medical Parliament in Oxford-street? The House of Commons is settling the question of Woman Dctoring, and of registration of non-medical degrees. The corporations are coming to an arrangement about co-operative examination and about a reform of the certificate system, and, possibly, when the Council meets in July, it will have only to shake hands over settled disputes, and deliver itself of *ex post facto* speeches.

Posthumous Honour to Sir Cordy Burrows, F.R.C.S.

It is seldom that any town pays such funeral honours to one of its citizens as those accorded on Saturday to this deceased member of the profession at Brighton. Thrice Mayor, the corporation and towns people were anxious to show their appreciation of his services, and when it became known that the family had acceded to the request for a public funeral, so numerous were the applications to join in it that the general purposes committee of the corporation were compelled to limit the numbers. The procession, to the number of 1,500, was formed in the grounds of the Royal Pavilion, the adjacent South Enclosure, and Pavilion Place. Amongst those who took part in it were over 500 Volunteers, representatives of all the local societies, the Railway Company, the Mayor and Corporation, and nearly every local medical man. The Mayor (Captain Abbey) and seven past mayors were the pall bearers. All the shops and places of business were closed, and also the Aquarium, the Rink, and other places of amusement, and the route to the Extra-mural Cemetry, above a mile and a-half in length, was lined with thousands of people, intent upon paying a last mark of respect to one of the most popular public men Brighton has known.

THE Lancashire magistrates have appointed Dr. Campbell Brown, of Liverpool, public analyst for the county.

THE Goldsmiths' Company have voted the magnificent donation of £1000 to "the Queen's Fund" of the London Hospital.

ANOTHER death from milk poisoning at Eagley occurred on Saturday, making eighteen in all since the commencement of the epidemic.

THE late Sir John Fisher, whose death we noticed in our last, directed that out of his estate, £100 should be given to the Royal Medical Benevolent College, Epsom, a like amount to the Society for the Relief of Widows and Orphans of Medical Men, and £50 each to the St. George's and Westminster hospitals.

Correspondence.

ROTUNDA HOSPITAL.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—I read with much interest your article upon the Rotunda Hospital, and being an old pupil of that valuable institution, naturally feel anxious for its welfare. Though few medical men can give large subscriptions, they can influence their friends and patients. Acting on your suggestion, I have been able in a few days to collect close upon £20, and feel conkdent if my brother medical men took up the matter, the sum still required (£1,000) would soon be forthcoming.

I am, Sir, yours faithfully,

CHARLES C. MAYNE, M.B., &c.

Ballybrack, March 31, 1876.

Subscriptions received in response to our suggestion :—

Dr. Mayne...	£1	1	0
Dr. Ringwood, Kells... ...	2	2	0
Dr. Jackson Cummins, Cork ...	1	0	0
Dr. West, Rathmullen ...	1	0	0

Literature.

FOOD: ITS ADULTERATIONS, AND THE METHODS FOR THEIR DETECTION. (a)

FROM Dr. Hill Hassall's well-founded reputation the present work was looked forward to with much expectation. These expectations are not disappointed, and the work is one not only highly instructive, but also readable and interesting. It is illustrated by upwards of 200 wood engravings, all well done, and some very good indeed. These engravings are of the greatest utility in conveying to the reader's mind a clear conception of the different matters described, and in demonstrating the services rendered by the microscope in the detection of adulterations. The waters examined in 1851 present a curious collection of material in them, and for the sake of water-drinkers, it is to be sincerely hoped that nothing of the kind is to be found in the waters of our great companies now.

In describing tea, coffee, and cocoa, the primitive structure of the genuine article is given in engravings, and described in the text: and then the different forms of adulterants are similarly given. This section demonstrates great ingenuity on the part of those who do the adulterating, especially in China, though the practice is far from being confined to the Celestials. Coffee is adulterated with ground beans, chicory, mangel-wurzel roots dried, acorns and other innocent materials; but there does not appear yet to be any scheme for making artificial coffee berries. Consequently by grinding coffee berries at home a cup of genuine coffee is still procurable. Chicory is itself largely adulterated. Sugar, it would appear, is apt to be a very nasty article if not refined; and one single pound of raw sugar has been found to contain 268,000 acari. The list of agents used to colour sugar in confectionary contains an alarming series of poisons, though some of the agents are innocent enough.

The different kinds of cereals, their preparation for the food of man, the adulterations used, the insects and fungi which infest flours, form some interesting reading. The ear-cockle, purples, or peppercorn (*vibrio tritici*) is an animalcule whose tenacity of life is very remarkable. The blighted grains are filled with a cotton-like substance and contain no flour. This substance is composed of myriads of eel-shaped animalcules, which, as soon as moistened with water, exhibit the most active movements. A most extraordinary circumstance connected with these animalcules is that they may be so perfectly dried that on the slightest touch they break up into powder, and yet, when moistened, they will revive, and become as active as at first. This operation may even be repeated several times before the vitality of the animalcules is finally destroyed.

A chapter is devoted to proprietary alimentary preparations, in which the glamour which hangs round them is rudely disturbed; and we should strongly recommend those who put their faith in these articles to leave Dr. Hill Hassall's book alone, otherwise their confidence might be shaken severely.

Milk of course is considered at much length, in a chapter well deserving of attentive perusal. The methods of adulterating butter are various; other fats, water, starch, but not ground flints or Thames mud, as have often been affirmed, are the agents used. Inferior salt butter is transformed into fresh butter by the following process: "Salt butter of very inferior quality is repeatedly washed in water in order to free it from the salt. This being accomplished, the next process is to wash it frequently with milk, and then to add a small quantity of sugar." Cheese is adulterated with potato starch, bean-meal, animal fats, and various objectionable colouring agents. The "jumpers" in cheese are very active animals, we all know; but the information afforded that Swammerdam once saw one jump out of a box six inches deep is rather startling.

Potted meats at one time had an unenviable reputation, but now they are very fairly what they are represented to be. The intense red given by Armenian bole is now no longer in demand. Horseflesh, it would appear, is valuable in the making of large sausages and polonies. It keeps them hard, and so they last better, if not sold; without it sausages run to water and become soft and pulpy.

Preserves offer great facilities for adulteration, while green preserves, like pickles, are artificially deepened in colour by the use of copper. Green bottled fruits are especially liable to such treatment. Spices, mustard, pepper, ginger, curry &c., are all subject to adulterations, which are readily revealed by the microscope. Vinegar also is commonly adulterated. Sauces, now in such common use, are not always free from objectionable constituents. It is written, "The only effectual remedy against certain of the adulterations of the sauces, especially the fish sauces, consists in their preparation at home." We must say, after careful perusal of this book, that it seems a little hard on the fish sauces to be singled out in this way, for there does not seem to be any particular reason for having them made at home more than other things, for the agents used in their adulteration are innocent—that is, if the bole Armenian is itself pure.

Malt beverages offer a fine scope for the dishonest trader, and as some also are sold at the price they are bought at from the brewer, a little mixing is the only

(a) "Food: its Adulterations, and the Methods for their Detection." By Arthur Hill Hassall, M.D. Lond., Physician to the National Hospital for Diseases of the Chest, &c. Longmans, Green, and Co. 1876. Pp. 884.

means by which a profit can be secured. This section of the work is very interesting, but the impression conveyed by its perusal is very decided in favour of having beer from trustworthy sources, and equally decided against promiscuous beer-drinking at taverns. It would appear, however, that drinking bitter beer is not so certain a method of taking strychnia as is generally supposed. Wine is subjected to very horrid practices, especially the means resorted to in the treatment of Burgundy, which rather sets one against that delicious and exhilarating beverage.

In the making of artificial port, cider takes a prominent part, and it would appear that the port wine so frequently ordered for invalids for its tonic properties is very apt to be a mixture of cider and vegetable astringents with brandy. It is written: "Great and scandalous tricks are played with the English gentleman's favourite after-dinner beverage."

In the distillation of spirits the great and chief objectionable agent produced is fusel oil. This is not added intentionally, but is produced by careless distillation, and it is a costly process to get rid of the vile fluid. There are various means of getting rid of it, but no cheap spirit is free from this unpleasant constituent. Doubtless the effects of intoxication in low neighbourhoods are due to some extent to the fusel oil in the spirits consumed there; the intoxication of bad spirits is of a wilder and more delirious character than that of pure alcohol.

A chapter is devoted to the utensils employed in the preparation and storage of food, and then follows a general summary of adulterations, the work closing with the Act for the sale of food and drugs. In conclusion, we may say that this work is one which ought to have large sale, for it contains a great deal of information on a very interesting subjects, the matter is well arranged, and the style is readable and attractive.

A GUIDE TO THE MICROSCOPICAL EXAMINATION OF DRINKING WATER. (a)

Dr. Macdonald, who is known to the profession as a competent microscopical observer, as well as a Professor of Hygiene at Netley, has furnished, for the use of officers of health and naval and military officers who have to determine the nature of the suspended matters in water used for dietetic purposes, "a guide to the microscopical examination and identification of the world of organic life met with in the rivers and streams of this country. Whatever may be the conclusions arrived at as to the sanitary import of the innumerable suspended matters in drinking water, it cannot be doubted that officers of health should be prepared to state what they are, and at the same time show some acquaintance with the natural history of the vegetables and animals which the microscope presents to view. The author has furnished a number of pen and ink drawings of the various creatures, to assist in their identification and classification; and although his plates cannot pretend to the fulness and delicacy of those to be found in many microscopical works at the present day, some artistic effect has been preserved, and they will answer the purpose intended, that of assisting in the work of the medical officer of health.

No attempt has been made by Dr. Macdonald to link together particular forms with special effects; he believes this scarcely possible at present, except in a limited extent, and because "there are numerous living creatures found in drinking water of which no good evidence of their hurtful action has been adduced." Much importance is however attached to them as showing the presence of organic impurities which serve as pabulum, or as indicating a source of putrefaction. These are points which seriously deserve the attention of those engaged in sanitary work, and whose duty it is to protect the public health.

In a brief introductory chapter, Dr. Macdonald explains the method of collecting sediments and the powers necessary for the recognition of the minuter forms of life under the microscope. He assures us that the true bacteria and filamentous algæ require the very highest powers of the instrument for their elucidation, while for the detection of some of the germs and matters suspended in water immersion lenses are necessary. In a work of the kind, we could have wished to see more space devoted to this part of the subject, and the examination of special samples of drinking water, and less to the classification of objects; nevertheless, those for whom the work has been designed, and young naturalists in particular, who are beginning to study and investigate the world of waters, will find much useful information.

THE NATURE OF LIGHT. (a)

This translation of Professor Lommel's lectures "On the Nature of Light" forms the nineteenth volume of the International Series of Messrs. King and Co. The list of works already issued is a goodly one, and cannot fail to command a large sale, both from their general excellence and from the low price at which they are published. We may expect the "International Series" to extend the growing interest in scientific pursuits. With special reference to Lommel's treatise, we have no doubt, from the dearth of books on the subject of which it treats, that it will become a useful manual. We are nevertheless of opinion that the publishers would have experienced no great difficulty in finding a lecturer on physics in this country who could have furnished a more complete treatise on the nature of light, and we venture to think in some respects better adapted to the wants of the English student in science. A translation, however well it may be done, is sure to suffer from a difficulty in fully comprehending the author's meaning. In the present volume inaccuracies occur which fully bear out this remark. For instance, at page 223 we read, "The intensity (or energy) of light depends on the *liveliness* of the vibrations." This word is repeated in a place where it seems to express quite another meaning. Again at page 250 we have, "Glowing fluids between the molecules of which the force of cohesion still exists." This somewhat unintelligible description certainly does not apply to elastic fluids, gases, and vapours. In other parts of the book words are employed which are not in ordinary use in English schools of science, as "fasciculous of rays," and "consistence of the chord," and probably neither of these expressions convey the exact meaning of the author, nor possibly will they be rightly understood by the student. These, however, are minor defects; on the whole the explanations are clear and exact, and the author is to be commended for not having embarrassed his readers with mathematical reasonings, which are omitted in the text, and simply given in an elementary form as an appendix at the end of each chapter.

The laws of reflexion, refraction, dispersion, and absorption of light occupy the first fourteen chapters, and which are demonstrated by experimental proof without reference to any theory of the nature of light. This comes forward prominently for the first time in the fifteenth chapter, in discussing Fiesnel's mirror experiment. The conclusion arrived at is of course in favour of what is now the accepted one—the undulatory theory. This chapter is clearly written, and nowhere have we met with so simple and intelligible an experiment to illustrate the formation of the rainbow than that presented in page 122. The application of lenses to the construction of optical instruments is briefly explained; and the different dispersive power of bodies is shown by comparing the spectra given by crown and flint glass, and wherein it is seen that although the total dispersion—that is, the length of the spectrum—is exactly the same, the mode of dispersion is different. By the position of the Fraunhofer lines in the two spectra, "it is rendered evident that the less refrangible rays are more closely approximated by passing

(a) "The Nature of Light, with a General Account of Physical Optics." By Dr. Eugene Lommel. London: Henry King & Co. 1875.

through the flint glass, whilst the more refrangible are separated further from one another by the crown glass." The treatise being wholly devoted to the consideration and investigation of the laws of light, *physical* optics, *physiological* optics, or the science of optics as applied to the phenomena of vision, has no place in its pages. Nevertheless, Professor Lommel's lectures will be found very useful to the student undergoing a scientific training and a preparation for a degree in science.

ROYLE'S MANUAL OF MATERIA MEDICA. (a)

It is nearly eight years since the last edition of "Royle's Manual of Materia Medica," edited by the late Dr. Headland was published, and this, the sixth edition, now comes before us under the editorship of Dr. John Harley. On comparing the last with the present edition, we find on every page evidence of the most careful supervision; in fact, the two works are wholly dissimilar. The botanical details, so characteristic hitherto of Royle's book, have been in great part eliminated, but still sufficient has been retained to meet the wants of the student in this respect. We confess to a feeling of disappointment that greater space has not been given to therapeutics, and to the consideration of the physiological action of medicines. It was, we think, to be expected of the talented author of "The Old Vegetable Neurotics," that he would give us a work pre-eminently characterised by richness in therapeutical details. Not only can this not be said of the present work, but a comparatively meagre account is given even of Dr. Harley's own valuable researches. On the other hand, the chemical and pharmaceutical portions of the work are full and accurate. We have looked in vain for any mention of coca, eucalyptus globulus, gelseminum, or monobromide of camphor, all of which have of late attracted no small amount of attention.

We read in the preface:—"Those who look for the results of experiments on mutilated animals in the following pages will not find them." If Dr. Harley implies by this sentence censure of unnecessary, irresponsible, or incompetent experimentation on the lower animals, we are wholly in accord with him; but if we are to understand that he would discountenance the subjection of the lower animals to all experimental research, we must enter an earnest protest *contra*. We are not "humane" enough to select man in preference to the lower animals when for the first time we desire to investigate the action of an agent of unknown properties.

Harley's edition of "Royle's Materia Medica" is, on the whole, a good work, carefully compiled, copious in matter, accurate in details, and one which we would confidently recommend to students and practitioners.

SLEEP AND DREAMING.

Professor Ferrier, of King's College, last week delivered a couple of interesting lectures on Sleep and Dreaming before a crowded audience at the London Institution. He commenced by observing that it was unnecessary to define what was meant by sleep and dreaming, seeing that the phenomena were so familiar. Nor did he think it necessary to take up time with an historical account of the speculations respecting the nature of these phenomena, nor of the fancies with which poetic imagination had clothed them. His object was principally to endeavour to reduce the phenomena of sleep and dreaming to the operations of strict natural laws. In order to do so it was necessary first to consider some of the laws and conditions of activity and repose in general. No living being is capable of continuous, unintermittent activity. All work implies waste, and the possibility of continuous life and activity necessitates, as a postulate, the constant repair of the waste of action. During active work the process of waste is in excess of the process of repair; hence if action is kept up a period comes when the stores of energy are expended. In action rest or repose follows, during which the waste is again repaired or made good, and the duration of this period of inaction will depend on the rate at which the process of repair proceeds. Illustrations of these general principles were given, the phenomena of the simplest organisms, such as the amæba, were considered, and it was shown that when such organisms were stimulated to constant and prolonged activity, as by heat, they after a time became exhausted and inactive, and remained quiescent until sufficient nourishment was again absorbed to repair the waste. What was true of amæba was true of the body in general and its various parts, for the body, in ultimate analysis, in reality consists of elements similar to amæba, or modifications of these, each with its separate life, but all working together to constitute the general life of the body. The various organs and tissues had, however, their own vitality, and within certain limits, were capable of action and inaction independently of that of the body as a whole. The muscles could not be kept in constant contraction. Exhaustion came on, and ultimately refusal to react to any stimulus which might be applied. This was well exemplified by the facts observed when the muscle of a frog was stimulated by the electric current applied to the nerve. The contractions became feebler and feebler, and ultimately ceased, the muscle becoming thoroughly exhausted. During the period of inaction, or sleep of the muscles the wasted tissues were again restored, the period of rest depending on the degree of exhaustion. What was true of the muscle was true, *mutatis mutandis*, of the organs of digestion. Some organs seem to be in a state of constant activity, and therefore might be thought to be exceptions to the general law laid down. This, however was not so, for in reality these organs, the heart and respiratory organs, were not in a state of constant, but of rhythmical activity, a period of action being followed by a pause or rest. The only difference between the heart and the voluntary muscles was that the periods of action and inaction of the heart were short, and followed each other in quick succession. In fact, if the pauses of the heart were all summed up and put together, it would be found that the heart rested or slept eight hours out of the 24, the sleep being in the proportion of one-third as compared with the hours of action or work. The brain, the organ of conscious activity, was kept in constant action during the day for many consecutive hours, and therefore it was necessary that there should be a correspondingly prolonged period of relaxation from action, and repair of the brain waste conditioned by all thought, solution, &c. The rest of the brain was sleep *par excellence*, but, in addition, sleep was the period during which the repair of the excess of waste over nutrition in the body generally occurred, in so far as it had not been made good during the day. This was proved experimentally by the researches of Pettenkofer and Voit, who showed that, in reality, more oxygen in the form of carbonic acid, &c., was given off during the day than was taken in, and it was during sleep that the excess of oxygen was stored up as a reserve fund against the possible needs of the following day. The relation of the duration of sleep to the period of action and its modifying circumstances were also considered, and a parallel drawn between the average duration of sleep and the rest of the heart. The physiological condition of active exertion on the part of any organ is an active circulation through it. The local increase of the circulation, or local hyperæmia, was brought about through reflex dilatations of the blood vessels, effected by the organs or tissues themselves. Muscles in a state of action drew a much larger supply of blood than when quiescent; so, also, the stomach during digestion. The same was observed in the brain during active thought. This had been demonstrated by direct experiment, and it was also shown indirectly by the fact that when a large amount of blood was draughted off to any one particular organ, there was an impoverishment of the circulation elsewhere. Hence deep thought, necessitating a large supply of blood on the brain, was unfavourable for digestion. Also, in deep thought the circulation became feeble in the extremities, hence cold feet, &c. In sleep the brain is anæmic. This has been shown by Durham, Hammond, &c., by way of direct experiment. This is proved, also, indirectly by the greater quantity of blood which circulates in the skin and extremities during sleep. Hence the danger of catching cold during sleep, because there is a greater radiation of heat from the skin. Whatever tends to abstract blood from the brain favours sleep. Hence digestion tends to cause sleep, as do hot drinks, &c., by drawing the blood supply from the brain to the stomach. Conversely, whatever tends to keep up the activity of the brain cells and the cir-

(a) "Royle's Manual of Materia Medica and Therapeutics." Sixth Edition. Edited by John Harley, M.D., F.R.C.P., &c. London: J. and A. Churchill, 1876.

culation tends to prevent sleep. This, therefore, is the effect of any stimulus applied to the senses, sights, sounds, thought, anxiety, &c. The opposite favours sleep. Hence night is the period of sleep, because sources of disturbance or stimulation of the organs of sense is diminished or altogether lulled. Uniformity of impression practically is the same as no impression at all; monotony, or uniform rhythm, tends to produce quiescence and predisposition to sleep. The commencement or cessation of the impression is the real stimulus, and therefore a person will awake suddenly when a constant sound is suddenly stopped.

Professor Ferrier's second lecture on Dreaming was scarcely so happy as that on Sleep. He maintained, however, that dreams are but the results of the partial activity of the brain, when the organs of attention are at rest. The most overworked functions rest first, and therefore the consciousness due to the least hard-worked parts of the brain often goes on, when the will, and what is due to will, is in complete quiescence. But, if this be so, how is it possible to explain the very common power of waking at any given time a person wills the night before? If the functions of attention are those which take the most profound rest, how is the mind aware that the hour on which the attention has been fixed before going to sleep has arrived? There are many things in this complicated structure of man that still will puzzle and confound the most subtle reasonings of the physiologist and philosopher.

Obituary.

IN MEMORIAM.—DR. LETHEBY.

THE numerous pupils and friends of the late Dr. Letheby will receive the news of his death with profound regret. He had long held a foremost position as a toxicologist and sanitarian, as well as a teacher of chemistry. Throughout a lengthy and honourable career he was closely associated with the London Hospital, where, many as have been the able and successful teachers, few have been privileged to continue their labours over a period of so many years; and few teachers in any school can have been greater favourites with students.

An intimacy of nearly a quarter of a century being unexpectedly terminated by his death, the shock seems sudden enough to deprive his pupil, colleague, and friend of the power to pen a few lines in his memory. Yet even thus early comes an invitation to write something about him, and affectionate admiration urges compliance, though the effort must be made amidst physical pain and weakness.

Dr. Letheby looked much younger than his years. He produced the impression of a man in his fullest vigour, both mental and bodily. Until quite recently, those who had not seen him for intervals of several years perceived no difference in his appearance, while many of his friends could scarcely realise that he had passed his 59th year.

He had, however, for several winters suffered from bronchial attacks, but change of air and repose seemed on each occasion to renovate him, and he returned to work with the characteristic energy which seldom failed to communicate his enthusiasm to those around him. Some of his friends occasionally feared that these attacks might become more serious, and would, perhaps, have willingly seen him relax a little more; but last winter he was better than during the preceding year. On the occasion of the Queen's late visit to the London Hospital he caught cold, but the attack seemed less severe than many from which he had easily rallied. Indeed, his recovery was confidently expected until within a short period of his decease, when extension of inflammation to the lungs took place and soon brought about the fatal issue.

At an early period Dr. Letheby lectured on comparative anatomy, and some specimens which he prepared are still in the museum of the London Hospital College. He also engaged in medical practice, but he soon gave himself up to chemistry and medical jurisprudence, in which he rapidly became *facile princeps*. At that time it was more common than it is now for barristers to indulge in brow-beating witnesses, and a certain Serjeant was notorious for this practice. In one of his first appearances Letheby was cross-examined with unusual severity by this very barrister, who had, it was said, already "annihilated" one or two witnesses. But the young expert, with the imperturbability of the most experienced, completely baffled the brow-beater, and his reputation was from that day established as a witness not to be trifled with.

His practice as an analyst and toxicologist was now steadily increasing. He also wrote critical reviews and other articles for higher-class journals, and that on various branches of science, for Letheby was not a chemist only, but possessed a profound acquaintance with a very wide range of subjects. At the same time he gave popular lectures at various institutions, and these were always attended by crowded and admiring audiences.

In 1846 he published in the *Lancet* a series of papers on the "Mode of conducting Post-mortem Examinations in Cases of Suspected Murder;" and these were followed by a course of lectures on "Practical Toxicology" in the *Medical Times*, 1848-50. From this time numerous articles of his continued to appear in the various medical and chemical journals on questions of legal medicine, toxicology, public health, and chemistry. On the resignation of Mr. Simon he was elected (1856) Medical Officer of Health for the City of London, in which capacity his annual reports were issued, and were regarded in all directions as most valuable contributions to sanitary science. It was, we believe, as much on account of these as of his chemical researches that a German University sent him the honorary degree of M.A. and Ph.D. Long before (1843) he had graduated as M.B. at the University of London. Some two or three years ago he resigned the City office, through which he was most known to the public. He had for years been the adviser of several of the gas and water companies, and perhaps no one equalled him in his special knowledge of this department of chemistry. When the Board of Trade appointed a chief gas analyst the post naturally fell to him, and he ceased of course to be the referee of any company. His work on the "Chemistry of Artificial Light" is well known to all interested in the subject, though it contains but a small part of his great and accurate knowledge of everything relating to it. He published regularly a weekly analysis of the metropolitan waters for the Association of Medical Officers of Health, of which he was elected President two years ago. Only last winter the MEDICAL PRESS AND CIRCULAR published in full an important paper on "Noxious Trades," which he read before the Association. His other papers, contributed to learned societies and journals, are too numerous to name here, but we may mention two which became important books. He delivered the Cantor Lectures before the Society of Arts in 1868, his subject being food. These lectures were published *verbatim* in the MEDICAL PRESS AND CIRCULAR, as well as in the *Journal of the Society of Arts*. The following year they were collected in a volume "On Food," which was soon out of print. Happily the author snatched time from his numerous avocations to revise a second edition, which appeared in 1872. The other work to which we have alluded is entitled "The Sewage Question." This also first appeared in the MEDICAL PRESS AND CIRCULAR, being a series of reports on all the sewage farms in the kingdom. These reports were first projected in a conversation between Dr. Letheby and the writer of these lines, and intended to be a joint production of these and a third writer. Dr. Letheby's earnestness, however, when once he had begun, carried on the work so actively, that the book may be looked upon as his own. It is full of analyses, and contains information based on his visits to the several sewage farms. When these reports were collected into book-form, the sheets were carefully revised by Dr. Letheby.

As a lecturer, Dr. Letheby was always popular. This was the natural effect of the fulness of his knowledge, his

forcible manner of teaching, his apt illustration, and his apposite experiments. Some men appear to lecture only to explain their experiments. Letheby always seemed to perform an experiment as an additional illustration of what he was inculcating. In his lectures even a familiar experiment seemed as if it had been designed on purpose to prove or illustrate the truth he was teaching, and then—his experiments never failed. Whether from carelessness or nervousness, there are some lecturers whose experiments are so often unsuccessful that in listening to them it is difficult to get rid of the feeling that there is some uncertainty about their teaching. With Dr. Letheby a single experiment seemed so naturally to grow out of the subject and decide it, that no doubt was admissible. As a chemist, sanitarian, and toxicologist, he has left much work behind him, but not enough to show how great was the personal influence he wielded beyond that which was derived from his exact and extensive knowledge, his untiring energy, his manly independence, and his fearless expression of his convictions when he felt called upon to state them. Some there may be who may fancy that at times he was severe. Let them remember that a man who endeavoured to allay the terror inspired by the early epidemic of cholera by exposing himself in every possible manner, to show that it was not contagious, was not likely to express in doubtful terms opinions he deemed of importance to the community.

As a friend, alas!—as a friend, his genial smile and hearty welcome will no more cheer the many with whom their memory must remain. Only his friends can realise the blank caused by his removal. To his bereaved widow the sincere sympathy of his friends must seem as inadequate a consolation as their deep regrets are a dim reflection of his worth.

P. J.

THE DUBLIN LOCK HOSPITAL.

The election of a surgeon to the Lock Hospital, Dublin, in the room of Dr. Morgan, took place on Saturday last, and was regarded with much interest by the profession in Dublin. The candidates were Drs. Macnamara, Mapother, Martin, Peele, Meldon, Thompson, Tweedy, and others less known; and the choice lay in the Board of Governors, consisting of twenty laymen. The contest, we understand, lay, after a preliminary division, between Dr. Macnamara and Dr. Martin, the former of whom was eventually elected. The choice which the Board has made will be unanimously approved, inasmuch as Dr. Macnamara's surgical character rests not a little on his experience in the treatment of stricture and venereal diseases.

THE COLLEGE OF SURGEONS OF IRELAND AND MR. GIBSON'S BILL.

The *Medical Times and Gazette* states in its publication for April 1st that the Royal College of Surgeons is about to petition against Mr. Gibson's Bill for the throwing open of Irish County Infirmary Surgeoncies to all qualified practitioners, and for putting on the Medical Register the State Medicine degree of Dublin University, and is of opinion that such "proceeding cannot but be regarded as ill-advised and injudicious, for the maintenance of such a monopoly (as that of the County Infirmaries) is utterly opposed to the spirit of the times, and must react on the College."

Our contemporary is misinformed. The Council of the College did petition against Mr. Gibson's Bill, without giving specific reasons, but the moment that Mr. Gibson undertook to introduce a clause to make the State Medicine degree registrable only *after* qualifications to practise, the College at once withdrew it opposition, thus showing that it did not choose to contest the question of the County Infirmary Surgeoncies, and that its opposition had nothing to say to the proposed infringement of the monopoly now enjoyed by the College.

The Council at the College deserve credit for their straightforward action in the matter, for they might—at least—have made Mr. Gibson's task a hard one, and they were not without good reasons why the qualification of County Infirmary Surgeons should remain exclusively with the College. We think the Council has acted properly; nevertheless the question was opened to argument.

RICHMOND WATER SUPPLY.

The town of Richmond on Thames determined some months ago to secure for itself a pure water supply, and this it appears gave offence to vested interests in dirty water. The oppressive conduct of the Southwark and Vauxhall Water Company, in having for several years supplied unfiltered water to the town, and lately greatly increased the charge for the same, could no longer be endured. The vestry, with praiseworty zeal and care for the health of the town, came to the rescue, and last year obtained a commission of inquiry into the water supply. Many eminent men were examined, and showed that the two most disgusting impurities revealed by the microscope in Thames water, as delivered by the Southwark and Vauxhall Water Company for dietetic purposes, are the fibres of partially digested meat and of variously coloured fibres of cotton rags. The presence of these in Thames water clearly indicated the two chief kinds of insoluble polluting matter, although chemical analysis cannot always trace to its sources the dissolved animal and vegetable impurities which it finds accompanying these insoluble materials. Nevertheless such impurities though not always offensive to the senses, are from a sanitary point of view of a very dangerous character, and therefore the Commissioners had no difficulty in coming to the conclusion that Richmond should be permitted to obtain a pure spring of water which Nature has stored up in the adjacent hills. The Vestry thereupon applied for powers to sink wells and find a better and cheaper supply for the town. This proved too much for the Directors of the Southwark and Vauxhall Water Company, and last week they applied for an injunction to restrain the vestry from proceeding with their works. Fortunately for Richmond, they were frustrated in this attempt. The vestry, in the interest of the inhabitants, disputed the right of the Southwark and Vauxhall Company to dole out bad water at an increased rate, and to force them to drink it to the danger of health.

The Vice-Chancellor took the same sensible view of the question, and in giving judgment, said "it was not to be supposed that because Richmond had tolerated water abounding in living organisms for ten years that they should be for ever debarred and stopped from saying that they would rest quiet no longer."

The German Hospital.—The thirty-first anniversary dinner of the German Hospital, Dalston, was held last night at Willis's Rooms, under the presidency of his Excellency Count Münster, the German Ambassador. The company numbered

about two hundred. The Chairman, in proposing "Prosperity to the German Hospital," observed that it had existed for 31 years, and had gone on increasing in prosperity, and that the numbers of those whom it had relieved last year (in-patients 1,327, out-patients 18,206) had been greater than in any previous year. He was glad to say that English hospitals never refused admission to a foreigner who had a recommendation; but in a German hospital, their countrymen had doctors and nurses who spoke their own language—they breathed, as it were, their native air, and this did more for them than medicine. The receipts last year were £9,669, expenditure £8,061, leaving a good balance in hand. Additional contributions announced by the Secretary amounted to £4,162, including £200 from the Emperor of Germany, £25 from the Duke of Edinburgh, and £50 from the King of the Belgians.

A Medical Missionary Society.—One of the most interesting meetings we attended, remarks the *Leisure Hour* for April, was an institution of which Edinburgh may well be proud—the Medical Missionary Dispensary. There is a dispensary open in the Cowgate for the relief of disease, managed by some of the leading medical men, clergy, and gentlemen of the city. The effort is to combine religious healing with medical. Kind ladies come and read suitable books, as well as the Bible, to the patients as they wait for attention. The students admitted there are learning to combine medical skill with missionary work. In Edinburgh they connect with their visits and physical inquiries, suitable inquiries as to the religious condition and welfare of those who seek their help. After this training they go forth under the patronage of a society as medical missionaries of the Cross to foreign lands, as to China, India, Japan, Africa, Syria, and other parts. Some of these men have been singularly useful in both departments of labour. As a memorial of the great African explorer and philanthropist, David Livingstone, a college or institution for the special training of medical missionaries is now being founded.

NOTICES TO CORRESPONDENTS.

☞ Correspondents requiring a reply in this column are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

Reading Cases.—Cloth board cases, gilt-lettered, containing 26 strings for holding each volume of the Medical Press and Circular, can now be had at either office of this Journal, price 2s. 6d. The postal regulations not allowing the Journal to be stitched, these cases will be found very useful to keep each weekly number intact, clean, and flat after it has passed through the post.

The "Obstetrical Journal."—Messrs. J. and A. Churchill present their compliments to the Editor of the Medical Press, and in sending him No. 37 of the *Obstetrical Journal* desire to say that it now enters upon its fourth year of publication, and with it a change of editors. Up to the present time Dr. Aveling has been the editor, but increasing professional engagements have obliged him to resign the position, and the Journal will in future be conducted by Dr. Galabin, Assistant Obstetric Physician to Guy's Hospital. The *Obstetrical Journal* is the only one published in this country which is exclusively devoted to the consideration of obstetrics and gynæcology.

Dr. Habershon will continue his lectures at the Royal College of Physicians of London this day and on Friday, at 5 p.m. Subject: "The Pathology of the Pneumogastric Nerve."

Mr. Cripps Lawrence will read a paper before the Harveian Society to-morrow evening, at 8 p.m., "On the Etiology and Treatment of Scrofulous Ophthalmia."

Communications, Enclosures, &c., have been received from—Dr. Billing, London. Dr. Day, Geelong. Dr. Day, London. Dr. Wise, Norwood. Dr. Palfrey, London. Mr. G. R. Jesse, Macclesfield. APPOINTMENTS.

Cameron, C. A., L.K.Q.C.P.I., F.R.C.S.I., Ph.D., Public Analyst for the County of Down.

Campbell, W. M., M.D., Surgeon to the Liverpool Northern Hospital.

Chabôt, H., M.R.C.S.E., L.S.A.L., Medical Officer to the Camberwell Workhouse Infirmary.

Davies, H., L.R.C.P.L., M.R.C.S.E., L.S.A.L., reappointed Medical Officer for the Llansamlet District of the Neath Union.

Hibberd, H. J., M.R.C.S.E., L.S.A.L., Medical Officer for Nos. 5 and 8 Districts, and Medical Officer to the Workhouse, of the Woodbridge Union, Suffolk.

Longbotham, G., M.R.C.S.E., L.S.A.L., Medical Officer for No. 2 District of the Middlesborough Union.

McKenzie, R. F., M.B., L.R.C.S.Ed., Medical Officer for No. 1 District of the Middlesborough Union.

Pearson, T. R., M.D., L.R.C.P.Ed., M.R.C.S.E., Medical Officer for No. 3 District of the Middlesborough Union.

Pegge, C., M.R.C.S.E., and L.M., L.S.A.L., Medical Officer for the Britonferry District of the Neath Union.

Sterling, R., L.R.C.P.Ed., L.R.C.S.I., L.M., Medical Officer, &c., for the Knocktopher Dispensary District of the Thomastown Union, co. Kilkenny, Sanitary Inspector for the Knocktopher Sub-District of the Thomastown Rural Sanitary District, and Medical Attendant to the Royal Irish Constabulary.

Wright, E. A., M.B., C.M., House-Surgeon to the Huddersfield Infirmary.

Birth.

Norris-Cane.—On the 17th ult., at Mullinavatt, the wife of Dr. J. B Norris-Cane, of a son.

Marriage.

Kesteven—Flint.—On the 28th ult., at the parish church, Croydon, W. H. Kesteven, M.R.C.S., of Tufnell Park Road, Holloway, to Beatrice, daughter of R. Flint, of Croydon.

Deaths.

Goddard.—On the 26th March, Samuel Goddard, M.R.C.S.E., of Burslem, aged 73.

Jones.—On the 30th March, at 406 Clapham Road, S.W., George John Jones, M.R.C.S.E., L.S.A., late of Prittlewell, Essex, aged 63.

Letheby.—On the 28th March, at Sussex Place, Regent's Park, N.W., Henry Letheby, M.B., Ph.D., &c., aged 59.

Mason.—On the 8th March, at Wyburn Villas, Surbiton, Charles Ignatius Mason, L.R.C.P.L. and M.R.C.S.E., aged 47.

O'Brien.—On the 24th March, at Maidstone, Walter Creagh O'Brien, L.R.C.P.Ed.

Pickering.—On the 22nd March, at the Orchards, Longparish, John Pickering, M.D., for nearly fifty years Resident Medical Officer at the Royal Military College, Sandhurst, aged 87.

Renny.—On the 25th March, at Exmouth, Charles Renny, C.B., F.R.C.S.E., late Surgeon-General Bengal Service, aged 84.

Thompson.—On the 20th March, at Sheffield, Edward Thompson, M.R.C.S.E., aged 67.

Turnbull.—On the 23rd March, at Clevedon, Gavin Ainslie Turnbull, L.R.C.S.Ed., Surgeon-Major, Army, aged 48.

IRISH POOR-LAW INTELLIGENCE.

BOYLE UNION.

At a summoned meeting of the guardians of above union on Tuesday last,

DR. KISBY'S CLAIM FOR FEES FOR VACCINATION PROSECUTIONS was read :—

The Abbey, Roscommon, 16th March, 1876.

Gentlemen,—As you have not favoured me with a reply to my letter of 28th February, I have prepared a civil bill for Boyle Sessions, where the liability of guardians for payment to a medical witness for his attendance in court at their request will be discussed and I hope settled.

I am, Gentlemen,
Your obedient servant,
JOSEPH BURKE.

The Guardians, Boyle Union.

A civil bill was also before the board issued at the instance of the Irish Medical Association on behalf of Dr. Kisby, medical officer of Ballyfarnon Dispensary District against the guardians of Boyle Poor-law Union for the sum of £1 1s. 0d. claimed by him for having attended at Ballyfarnon Petty Sessions on the 22nd October 1875, in proceedings instituted by the guardians against divers persons (defaulters) under the Vaccination (Ireland) Acts.

Clerk—In this case there was a regular sell. I was not at the Petty Sessions. If expense was incurred the Board would have to pay it.

The Chairman said Dr. Kisby had given instances of medical officers having been paid for attending at Petty Sessions to give evidence in such cases ; one of those instances occurred at Kells.

Clerk—Yes, Sir, all that appeared in the MEDICAL PRESS.

Mr. Mullhill—This is the first time a medical officer made such a claim here.

Clerk—If I had been aware of the circumstances I would have attended at the Petty Sessions.

Mr. Mullhall—You will have an opportunity of doing so.

Mr. Devine—Dr. Kisby had not to walk 20 yards from his own house to attend the sessions.

Clerk—He incurred no expense.

Mr. Sharkey—He is not entitled to any expense at all.

Mr. Powell—It was not asked by any of the doctors before, perhaps.

Mr. MacDermot—This matter was fully considered before, and was refused on the ground of no expenses having been incurred.

Mr. Powell—Perhaps he employed a car to cross the road.

After some other remarks the clerk was directed to communicate with Mr. Harkan, and instruct him to defend the case, which will come before the chairman at the Boyle Quarter Sessions on the 31st instant.

THE CORONERS (DUBLIN) BILL.

THIS Bill has been under the careful consideration of the Council of the Irish Medical Association, who have presented to Parliament through the hands of the Hon. David Plunket the following petition for its amendment :—

The Petition of the President, Vice-Presidents, and Council of the Irish Medical Association,

Humbly sheweth,

That your petitioners having considered the provisions of the Coroners (Dublin) Bill, consider that while many of its clauses deserve approval, said Bill is deficient in not providing for competent medical evidence at coroners' inquests, and that it is objectionable in proposing the abolition of one of the coronerships now existing in Dublin.

That your petitioners are aware that in Dublin as well as in other districts in Ireland, in consequence of the vagueness of the wording of the law which regulates coroners' inquests, the testimony of the medical practitioner who has been last in attendance upon the deceased person at the time of death or recently before it, and who would therefore be capable of giving reliable evidence as to the cause of death, is usually withheld from the consideration of the coroners' jury, while a person is called as medical witness who has never seen the deceased person alive, who can have no personal knowledge whatever of the matter, and who frequently testifies as to the cause of death without any post-mortem examination, or any other source of information than an external view of the body and the hearsay statements of other persons.

That the Act 9th and 10th of her Majesty's reign, chap. 37, sec. 32, provides as regards medical evidence that the coroner "shall summon as such witness any legally qualified medical practitioner, being at the time in actual practice, at or near the place where such death happened." The intention of Parliament being, as your petitioners submit, that the medical practititioner acquainted with the circumstances of the death should be heard in evidence, but your petitioners are aware that in Dublin and in certain other districts in Ireland the words "at or near the place" are construed by the coroner to include an indefinite distance, even outside the county, and in Dublin two individual practitioners who possess no special qualification as experts, and who do not reside "at or near the place of death," have been employed by the coroners in all cases to testify as to the cause of death of pessons whom they never saw alive.

That in the case of persons dying in a public institution, or

brought to the same for the purpose of receiving medical treatment, and found to be dead upon arrival, it is usual in Dublin for the body to be removed to the Morgue, and an inquest being held, the medical officer of such public institution who saw and attended upon the deceased person is not called to give evidence, but the testimony of either of the medical practitioners above referred to is taken, who have never seen the deceased before death, and who frequently receive fees for making post-mortem examinations which the testimony of the hospital surgeon would have rendered unnecessary.

That your petitioners respectfully submit that the withholding of the evidence of the medical practitioner who was in attendance on the deceased person immediately before death, or who practises in the immediate neighbourhood, and the substitution for it of the testimony of a person who has no special knowledge of the cause of death, is contrary to public advantage, being calculated to mislead the jury, and indirectly to enable crime to pass unpunished.

That your petitioners, therefore, pray your Honourable House that in this or in any Bill dealing with the law of coroners' inquests in Ireland, amendments may be inserted which will require the coroner to summon as a medical witness the medical practitioner last in attendance on the deceased person, or in his absence the medical officer of the dispensary district or sub-district in which the death occurred; and your petitioners furthermore pray that your Honourable House will not assent to any Bill by which a single coroner shall be charged with the holding of inquests for the whole city of Dublin.

And your petitioners will ever pray.

CARRICK-ON-SUIR GUARDIANS.

FEE FOR EXTRA MEDICAL ATTENDANCE.

Mr. Lawrence, R.O., stated that he paid a fee of two guineas to Dr. Fitzgerald, dispensary surgeon, for his attendance in a very urgent case which came within his duty as relieving officer. The Chairman questioned the power of the relieving officer to pay a fee of two guineas for one visit, and asked the Clerk to read that portion of the Poor-law Act bearing on the case. The Clerk read section 7, 10th Victoria, cap. 31, wherein it was stated the relieving officer had power to employ medical aid in such a case, but no fee was specified.

Chairman.—A guinea ought to be quite sufficient.

Mr. Conolly.—I think so, too. If a man sent for a doctor he would not charge more than £1.

Mr. Lawrence.—The money is paid, and I have done it frequently before.

The board refused to grant an order, believing that a guinea was quite sufficient.

NAAS UNION.

The Chairman then read as follows :—

Naas, 28th March, 1876.

"Sir,—My attention has been directed to a report of the proceedings of the Naas Board of Guardians as published in the *Leinster Express* newspaper of the 11th March instant, in which Mr. Daly (master of workhouse) is reported to have stated that he never knew of the medical officer being called on to attend on cases of midwifery in the workhouse, and that these cases were usually attended by the old women of the house. This statement implies a very serious charge against the nurse directly and against me indirectly, and is of such a nature as in my opinion to call for prompt investigation on the part of the Board of Guardians.

"If Mr. Daly knew that Mrs. Coonan was in the habit of neglecting her duties, and allowing lying-in women to be attended by old women who happened to be in the house it was his duty to have reported to me, which he never did; but I believe it will be found that Mr. Daly's statement with regard to the nurse is incorrect and unfounded.

"As regards myself, I beg to state that if Mr. Daly never knew of my having been called upon to attend on cases of midwifery, he should have known that such occurrences have repeatedly taken place, as can be readily proved, and that on several occasions my attendance was called for, and operations performed successfully.

"F. J. Falkiner, M.B., Medical Officer,
"Naas Workhouse.

"To the presiding Chairman, Board of
"Guardians, Naas Workhouse."

Mr. Driver.—It is his business to attend on those cases.

Mr. Dunne.—And he is well paid for it.

Chairman.—I think you will have to appoint a midwife.

WESTPORT GUARDIANS.

SANITATION.

The Medical Officer reports as follows :—"I have recently inspected the Westport Shambles on several occasions owing to various applications having been made to me as regards the filthy condition in which it is invariably kept. I found on each occasion heaps of filth, rotten fish, and decomposing blood covering its surface, and an odour from it was sufficient to cause a plague among the people living in the locality, particularly in warm weather; and I recommend that the surface be asphalted, with a proper incline to convey the surface water into a drain leading from it, and that the asphalte be washed with water and properly swept every morning."

SWINFORD UNION.

WORKHOUSE COFFINS.

Mr. Peyton complained that a coffin, stated to him to have been supplied by the union, through the relieving officer of Swinford, was so bad and so poor that it had to be tied with ropes to prevent the corpse from falling through (oh, oh).

Chairman—I am very glad to hear you make the complaint, Mr. Peyton. Similar complaints have been made to me, and that even the shrouding was removed (oh, oh, and shame).

Dr. Roughan said the relieving officer was accountable.

Relieving Officer Horkan said he knew nothing about it. He gave no order.

The undertaker said he never supplied coffins in that way; he could show that his were well and decently made

Mr. Peyton said the shrouding was removed. There was none to be seen in the coffin (oh, oh).

The undertaker said he never omitted to supply shrouding.

The matter was to be further inquired into.

PILTOWN DISPENSARY.

A letter was received from Dr. Murhhy, stating that during the last three weeks he had been performing the duties of Dr. Bowers, of Piltown, who, owing to a severe attack of illness, is unable to discharge his duties as dispensary surgeon. Dr. Murphy sought the usual remuneration for such services, but the dispensary committee had refused to grant any compensation. The Act of Parliament having been referred to, it was found that the board of guardians could grant two guineas a week for such services, and after discussion, a motion was passed, without opposition, to pay Dr. Murphy £2 2s. per week. Dr. Bowers has since died.

LIST OF ENTRIES IN THE REGISTER OF THE BRANCH MEDICAL COUNCIL (IRELAND) FOR THE MONTHS OF FEBRUARY AND MARCH, 1876.

FEBRUARY.

FEB. 1st.—Popham, Thomas Dalton, 42 King Street, Cork, M.D. 1875, and M.Ch. 1875, Qu. Univ. Irel.

3rd.—Morewood, Samuel Rowley, Draperstown, co. Londonderry, Lic. Roy. Coll. Surg. Irel., 1875.

4th.—O'Connor, Michael Roderick, Murroe, Limerick, M.D. 1875, and M.Ch. 1875, Qu. Univ. Irel.

8th.—Yeo, Robert, Frederick, 20 Herbert Street, Dublin, Lic. 1875, and Lic. Mid. 1875, K. Q. Coll. Phys. Irel.; Lic. Roy. Coll. Surg. Irel. 1875.

9th.—Roe, St. George Joseph, Newport, co. Mayo, Lic. Roy. Coll. Phys. Edin. 1876; Lic. Roy. Coll. Surg. Edin. 1876.

11th.—Johnston, Percy Herbert, 2 Park View, Cork, M.D. 1875, and M.Ch. 1875, Qu. Univ. Irel.

11th.—Fogerty, George Joseph, Henry Street, Limerick, Lic. Roy. Coll. Phys. Edin. 1876; Lic. Roy. Coll. Surg. Edin. 1876.

14th.—O'Hagan, Patrick John, Carrickmacross, co. Monhagan, Lic. Roy. Coll. Surg. Irel. 1875, Lic. 1876, and Lic. Mid. 1876, K, Q. Coll. Phys. Irel.

15th.—Christal, John, Benbulben, Grange, co. Sligo, Lic. Roy. Coll. Surg. Irel. 1875, Lic. 1876, and Lic. Mid. 1876, K. Q. Coll. Phys. Irel.

16th.—Howe, Jonas, Glouverinane, Kilbrittain, Bandon, co. Cork, Lic. Roy. Coll. Phys. Edin. 1875; Lic. Roy. Coll. Surg. Edin. 1875.

18th.—O'Meara, Michael Aloysius, Bridge Street, Waterford, Lic. R. Coll. Surg. Irel. 1874, Lic. 1875, and Lic. Mid. 1875, K. Q. Coll. Phys. Irel.

19th.—Young, Alexander Thomas, 7 Ardenza Terrace, Monkstown co. Dublin, Lic. R. Coll. Surg. Irel. 1875, Lic 1876, and Lic. Mid. 1876, K. Q. Coll. Phys. Irel.

21st.—McCoy, Thomas Joseph, Clare House, Kilcoleman, co. Limerick, Lic. R. Coll. Surg. Irel. 1874, Lic. 1876, and Lic. Mid. 1876, K. Q. Coll. Phys., Irel.

26th.—Browne, Chas. James, Bandon, co. Cork, M.B. Uinv. Dub. 1876.

28th.—Sigerson, George, 17 Richmond Hill, Rathmines,, co. Dublin, M.D. 1859, and M.Ch. 1865, Qu. Univ. Irel. Lic. K. Q. Coll. Phys. Irel. 1875.

MARCH.

MAR. 2nd.—Johnston, Wm. Thomas, Royal Hos. Belfast, M.D. Qu. Univ., Irel., 1875.

4th.—O'Doherty, John Jerome, Buncrana, co. Derry, Lic. R. Coll. Phys. Edin. 1876, Lic. Fac. Phys. Surg. Glas. 1876.

4th.—Griffith, Robert, Cootehill, co. Cavan, Lic. R. Coll. Surg. Irel. 1872, M.B. Univ. Dub. 1874.

6th.—Creagh, James, Mallow, co. Cork, Lic. R. Coll. Surg. Irel. 1873, Lic. R. Coll. Phys. Edin. 1874.

7th.—Russell, George Mark, Mallow Street, Limerick, Lic. R. Coll. Surg. Irel. 1875, M.B. Univ. Dub. 1876.

13th.—Browne, William James, Londonderry, Lic. R. Coll. Surg. Irel. 1876.

16th.—Hartford, Henry Wm., Portarlington, Queen's County, Lic. R. Coll. Surg. Irel. 1875, Lic. 1875, & Lic. Mid. 1875, K. Q. Coll. Phys. Irel.

20th.—Fergus, Samuel, Moy., co. Tyrone, M.D. Qu. Univ. Irel. 1875.

22nd.—Jennings, John Bray, 74 Marton Road, Middlesborough-on-Tees, Lic. R. Coll. Surg. Irel. 1875.

22nd.—Hederman, Wm., Ballinleena, Kilmallock, co. Limerick, Lic. R. Coll. Surg. Irel. 1875, Lic. 1876, & Lic. Mid. 1876 K. Q. Coll. Phys. Irel.

22nd.—O'Connor, John Francis, Fox Hall, Charleville, co. Cork, Lic. R. Coll. Surg. Irel. 1875, Lic. 1876, & Lic. Mid. 1876, K. Q. Coll. Phys. Irel.

22nd.—Browne, Abraham Walter, Killymaddy, Castle Caulfield, co. Tyrone, Lic. R. Coll. Surg. Irel. 1875, Lic. 1876, & Lic. Mid. 1876, K. Q. Coll. Phys. Irel.

23rd.—MacCarthy, Charles Edward De Lacy, 4 Crosthwaite Park, Kingstown. co. Dublin, M.B. Univ. Dub. 1873.

25th.—Woods, Charles Rolleston, Parsonstown King's County, Lic. 1875, & Lic. Mid. 1875, R. Coll. Surg. Irel., M.B. Univ. Dub. 1876.

27th.—Nolan, Cornelius Joseph, Ballyan, Shanagolden, co. Limerick, Lic. R. Coll. Surg. Irel. 1875, Lic. 1876, & Lic. Mid. 1876, K. Q. Coll. Phys. Irel.

THE BIRTH AND DEATH RATE OF IRELAND.

DURING the quarter ended 31st December last, there was registered in the 793 Registrars' Districts in Ireland an annual birth-rate of 24·1 in every 1,000 of the population—an annual mortality of 17·3 per 1,000.

In England, during the same quarter, the birth-rate represented was 34·7, and the mortality 21·8.

The registered births in Ireland are again under, the deaths over, the average for the corresponding quarter of the previous five years, the increase in the mortality being chiefly amongst the old. The deaths from scarlet fever are slightly over those in the preceding quarter, the disease still proving very fatal in Ulster, but the returns show an almost complete freedom from small-pox, and the total mortality from the principal zymotic diseases is under the average for the fourth quarter, and less than in any quarter since the September quarter of 1873.

The rain-fall of the quarter measured 12·425 inches, being considerably over the average, more than double that of 1871 or 1873, and higher than any of the last 10 years except 1872.

The average number of inmates of workhouses in Ireland was considerably under that for the fourth quarter of 1874, but there was a slight increase in the number of persons receiving out-door relief.

Births.—The births registered during the fourth quarter of last year amounted to an annual ratio of 24·1 per 1,000 of the estimated population. The average number during the corresponding quarter of five years was 25·1 per 1000.

The birth-rate represented by these returns was highest in the following counties, viz.:—Mayo, 28·3 per 1000; Antrim, 27·9; Kerry, 27·7; Dublin, 25·9; and Galway 25·8. The counties having the lowest birth-rates were Meath, 20·2, per 1000; Queen's, 20·5; Longford, 20·8; Wicklow, 20·9; Fermanagh, 21·0; Carlow, Wexford and Monaghan, each 21·2; Tyrone, 21·8; and Sligo, 21,9 per 1,000.

Deaths.—The deaths registered afford an annual ratio of 17·3 per 1,000 of the population, which rate is 1·0 per 1,000 over the average for the fourth quarter of the preceding five years.

The deaths registered in Leinster afford an annual rate of 20·0 in every 1,000, in Munster 17·5, in Ulster 17·3, and in Connaught 12·8.

The counties having the highest death-rates were :—Dublin, 25·9 ; Carlow, 21·4 ; Antrim, 20·5 ; Limerick, 19·9 ; and Waterford, 19·2. Those having the lowest death-rates were :—Mayo, 11·2, per 1,000 ; Sligo 12·6 ; Fermanagh, 13·3 ; Galway and Leitrim, each, 13·5 ; Roscommon, 13·6 ; Longford, 14·1 ; Clare, 14·4 ; Donegal, 14·6 ; and Kerry, 14·8 per 1,000

DEATH FROM PULMONARY HÆMORRHAGE AT THE FULL TERM OF PREGNANCY: DOUBLE UTERUS AND VAGINA.

M. Budin publishes the following case in *Le Progrès Médical*:—A strong, healthy young woman, 24 years of age, was admitted into La Maternité, having, an hour and a-quarter previously, spit up a large quantity of blood. She had arrived at the full term of her first pregnancy, and had for a short period coughed slightly. She was scarcely placed in bed when the hæmoptysis returned so suddenly and abundantly that she died in an hour and a-half. More than ten minutes after death the Cæsarian operation was performed, and the child, whose heart had almost ceased to beat, was resuscitated after three-quarters of an hour's insufflation. The autopsy of the mother revealed the presence of tubercular granulation at the summit of both lungs, and two small caverns, the size of filberts, in the left, to one of which the hæmorrhage could be traced. The uterine mass was discovered to consist of two organs, and corresponded to the "uterus bipartitus globularis" of M. Lefort's classification. Pregnancy had taken place in the right uterus, which measured 20 centimetres in length, and 11 in breadth, and was separated from the left by a very slight furrow on the surface. The cervix of the right uterus was not obliterated, its canal measuring 5 centimetres and containing a mucous plug. The cervix of the left uterus, on a plane lower than the right, measured 4 centimetres in length, and was also completely filled by a mucous plug; and the body and cervix together measured 18 centimetres in length, and 7 in breadth. The mucous membrane and glands in its interior were greatly hypertrophied, and presented lobulated masses of a greyish-red colour, forming, in certain places, true polypi. This hypertrophy was most marked at the fundus, and diminished towards the cervix. The cervices opened into distinct vaginæ, each situated on the same plane, the one to the right and the other to the left, and each equally permeable. The vulva was normal, except that the median partition was attached to the fourchette. To each side of the combined organ was attached a round ligament, Fallopian tube, and ovary, the true macula lutea being situated in the right ovary. M. Budin draws attention to the right cervix retaining its entire length, so that the period of the pregnancy could not be determined by it.

CONSIDERATIONS UPON SOFT CATARACT OCCURING IN MIDDLE LIFE, ITS PATHOLOGY AND TREATMENT. (a)

By Archibald Hamilton Jacob, M.D. Dub., F.R.C.S.I., Surgeon to the Dublin Eye and Ear Infirmary. Formerly Ophthalmic and Aural Surgeon to the City of Dublin Hospital.

In the Medical Press and Circular for November 24th, 1875, I published a case illustrative of the pathogeny and treatment of cataract, which has suggested to me certain speculations worthy, I think, of the consideration of the Society, and upon which I shall be glad to hear its opinion expressed. With your permission, Mr President, I will recapitulate as briefly as possible the points of the case as an introduction to the subject.

About two years since I was consulted with reference to the sight of a lady, æt. 55 years, who had been for a long time a confirmed invalid. She had suffered from liver disease, which gave rise to chronic constipation, and frequent attacks of severe bilious vomiting and diarrhœa. Her tongue was habitually foul, and her digestion always more or less out of order, and she presented the marasmatic appearance which is frequently seen in conjunction with cataract. One eye was perfectly blind from a fully-developed, milky-coloured, stellate cataract, which had taken a year and a-half to mature. The other lens was in the second stage of opacity, and the disease was of the same type, and was accompanied with a good deal of darting pain in eye-ball and temple, abundant muscæ, and occasional phosphenes. The retina was, of course, not observable, but the iris was active and healthy-looking, and the amount of sight was as much as could have been expected from a healthy retina when the degree of opacity was considered.

The course to be advised in this case was by no means easily determined on. It was evident, bearing in mind the chronic and apparently irremediable digestive derangements, the frequent attacks of vomiting, and the poor state of nutrition which the patient presented, that extraction was strongly contra-indicated. A large corneal flap, I thought, would probably slough, while I feared that an attack of retching would possibly cause a loss of vitreous, even through a small corneal opening, and that the healing of any wound would be likely to be tedious. On the other hand, I was aware from experience that in such cases solution of the lens was always excessively slow, and in diabetic cases could hardly be obtained by any exercise of patience. As, however, an analysis of the urine showed no sugar, I decided in favour of the operation for solution at least as a preliminary measure. I broke up the fully-developed cataract freely by the needle through the cornea. As I anticipated, the absorption was very slow, but was, nevertheless, steady and perceptible. After about three months vision was slowly improving, which, however, had the effect of making the patient more impatient than ever, and, as a suggestion of an extraction operation was not favourably received, I repeated the operation twice at intervals of six weeks. On repeating the operation a fourth time I tore the lens substance very freely. Shortly afterwards glaucomatous symptoms began to develope themselves, the tension of the eye-ball increased, acute lancinating pain set in, the iris began to look muddy, and the sclerotic assumed a dusky hue. After a futile effort to bring back the eye to a healthy condition by leeching and other treatment, I advised that a Græfean operation should be done, for the purpose of removing any portion of lens which might be causing irritation, and at the same time making an iridectomy. This was accordingly done, and although an attack of bilious vomiting occurred two days afterwards, the section healed well and firmly, the glaucomatic sym-

(a) Read before the Surgical Society of Ireland, March 24. The discussion will be found on page 301.

ptoms began to abate and continued to do so until vision sufficient for large print was achieved.

Meanwhile the second eye had become perfectly cataractous, and had been once operated on with the needle, and the lens was in course of very slow solution. The effect which followed upon, if it were not the consequence of, the the last breaking up of the cataract in the first operated eye had been so alarming that I could not venture a repetition of the operation on the last eye. Unhappily, a month afterwards the glaucomatous symptoms again developed themselves in the first eye and the vision gradually faded away, until I was obliged to relinquish hope of it, and to look to the remaining cataractous eye as the only available resource. The glaucoma became so acute and seemed to threaten the good eye so seriously that I proposed to operate again on both eyes, to make a fresh and larger iridectomy in the bad eye, and to extract the cataract in the good one. This suggestion I was led to make partly because the recovery of sight, by the absorption of the opaque lens, appeared indefinitely distant unless the discission operation could be repeated several times, but principally because the condition of digestion and nutrition in my patient had so far improved that there was no longer so grave a reason for refraining from an extraction operation. The bilious vomiting which I most feared had ceased altogether, and the general health of the patient was much better. Accordingly I operated on both eyes, the patient being placed under the influence of ether. In the glaucomatous eye I removed a large section of iris below and internally, and I then extracted the lens from the other eye by Liebreich's method. Two days after the operation there was a considerable hæmorrhage into the anterior chamber of the iridectomised eye, which was the only untoward occurrence. In five days I removed the coverings from the cataractous eye, and found the flap well healed, the pupil quite natural in shape, and all as well as could be desired. Since then, after a lapse of now 18 months, the pain and excitement of the glaucomatous eye have entirely subsided, but the vision has only slightly, if at all, improved ; but the sight of the cataractous eye is, with the help of suitable spectacles, able for the smallest test-types.

The issues raised by this case are numerous and very instructive, involving as they do several subjects of controversy and of obscurity in ophthalmic surgery.

In the first place it presents for our consideration the question as to the cause of soft cataract occurring late in life, without any renal disease, or any local eye symptoms in excess of those which usually accompany lenticular opacities. In the present case there were troublesome derangements of the assimilative organs, but generally speaking, such symptoms are not prominent, though there may be appearances of malnutrition and premature decay about the patient.

It occurs usually between the ages of 40 and 50, and I don't recollect to have ever seen this form of soft cataract at an earlier age than 35 or later than 60. The patient is generally anæmic, and looks as if prematurely aged ; yet this form of cataract is seldom seen in persons whose constitutions have been injured by hard work or dissipation ; but, on the contrary, seems to affect ladies who have lived a retired life, and men of rigidly temperate habits. There would also seem to be a marked hereditary tendency to this disease, or rather to the cachexia which gives rise to it, for I have more than once remarked it in brothers and sisters of the same family, and of about the same middle age, and in persons whose parents were said to have gone blind of it at about the same period of life. In one family in Dublin I operated with the needle on four eyes in a brother and two sisters, and a third sister was operated on in India about the same time for the same disease in both eyes. Here were cases in which all the circumstances of life were different : the brother was a clergyman, resident in the country, and engaged in active parochial duty ; two of the sisters were unmarried, and led the quietest life in Dublin ; the third sister was married and the mother of a family in India, having resided there, engaged in all the turmoil of social gaieties, for thirty years. In this family there was no history of eye disease in parents, uncles, or aunts, and, after careful inquiry, I failed to discover the least constitutional clue to the cause.

On this subject Mr. Haynes Walton says : "Lenticular cataract, which is seen after the 45th year of age, cannot generally be accounted for. It appears without any palpable cause. Pathology and physiology do not afford any elucidation, and all the theories which have been advanced concerning it, some of which are very ingenious, are untenable. It is likely that complications often exist and escape notice because we are not able to detect them. Perhaps all idiopathic cataracts are the result of complicated disturbance in the ocular circulation."

Mr. Brundell Carter also, speaking of the cause of cataract in advanced life, which he defines to be "an expression of gradual failure of the power to renew the lens fibres in their transparency," says : "Of the causes which determine its early, or, so to speak, premature occurrence in some persons, we have little knowledge. The influence of disturbed circulation, especially in the common form of retarded admission of arterial blood and retarded escape of arterial blood, must be too obvious to need explanation. But a great number of cases of cataract—nay, probably a great majority—cannot be referred to either of these conditions. The change takes place in persons of both sexes, in the robust and in the feeble, in all ranks and conditions, and in no apparent connection with antecedent habits and occupations."

The theory of the inflammatory origin of these lenticular opacities may, I think, be dismissed without much consideration. We are, of course, familiar with cataract as a consecutive result of vitreous or choroidal disease ; but in the soft cataracts of middle age all inflammatory symptoms are absent, and there is scarcely even the small amount of retinal excitement which is shown during the development of hard cataract by muscæ and, occasionally, by phosphenes.

"It is said," says Mr. Haynes Walton, "that there are pathological changes allied to atrophy which are produced by inflammation, a sort of lentitis ; but inflammation of the lens and its capsule occurring alone may be said to be unknown. The inflammation occurs only as an extension of disease from other parts of the eyeball." Nor do the microscopic examinations of cataracts reveal the inflammatory nature of the opacity, the change being rather an alteration of molecular condition than a deposit of a new product or a destructive inflammation of the lens fibres.

The theory of the production of cataract by disturbances of the exosmosis through the capsule seems to me to be that most consonant with observed facts.

Kunde, whose opinion is quoted by Mr. Bader, has adduced many observations showing that opacity of the lens can be caused in animals, as in frogs, cats, and dogs, by the establishment of conditions interfering with the exosmotic processes which administer to the healthy nutrition of the lens, the activity of which is well shown by the interesting experiments of Dr. Bence Jones and M. Dupré. Thus the administration of sugar and the various mineral salts in large quantity occasion the formation of a cataract resembling that which occurs in the later stage of diabetes, and which may be attributed to the same cause—an excessive density of the blood leading to exosmose of fluid from the lens and the formation of vacuolæ in its substance, accompanied by the deposition in an insoluble form of calcareous and other salts.

It seems to me, however, that the distinction between the soft cataract and the amber-coloured senile form of old age is not sufficiently considered, for they seem to me to be essentially different, and, though probably produced by the same cause, may arise from the operation of that cause in opposite directions. The soft opacity is apparently attended by a swelling of the lens substance sufficient, frequently, to bulge forward the iris, and on extraction of the lens the cortex appears to consist of a mass of mace-

rated pulp. We know that the admission of aqueous humour to the lens substance by laceration of the capsule will produce a cataract undistinguishable from the soft opacity of middle life, and that, in process of time, this contact will end in a solution of the opaque lens substance. On the other hand, the amber senile lens bears all the appearance of shrinking and drying, and, on extraction, proves to be tough and waxy in the nucleus, and small in bulk. Regarding these circumstances together, viz. :—the ill-nourished, anæmic, appearance of the patient ; the apparent increase in size of the lens ; the close resemblance of it to the cataract to that produced by the ingress of water to its substance ; the waxy shrunken appearance of the ordinary senile cataract, and the impossibility of producing that form by any known means ;—I have formed a theory—which I have already called a speculation, and no more—which it pleases me to believe accounts for the facts as well as any other hypothesis. I conceive that in the subjects of soft middle-age cataract the lacteal system may be deranged, that it may fail to convey the requisite proportion of chyle to form the due proportion of globules, and that consequently the menstruum of the blood may come to be proportionately in excess ; that, thereupon, an endosmosis through the capsule may take place, a consequent swelling and maceration of the lens substance, and a molecular change causing opacity. On the other hand, if the water of the blood were to decrease in proportion to its saline and globular contents, as we are told it does in advanced life, an exosmosis from within the capsule would take place—in fact, a sort of drying process, accompanied by consequent shrinking in bulk and resulting opacity.

I have dwelt at too great length on this speculation, because it bears upon the question of the chances of absorption of the lens substance, and, therefore, would go some distance to decide the propriety of operating for extraction or for solution, as is usual in the treatment of soft lenses of this sort. In the case which I have narrated I had a reason for declining to extract, apart from my belief that the prospects of absorption were remote, for the patient was in such a condition of indigestion and frequent vomiting that I could not well risk a large corneal incision. The result of my repeated discission operations on both eyes satisfied me that in these cases the absorptive qualities of the eye are greatly impaired. In former cases I had operated uniformly on this class of cataracts with the needle, but had been obliged to repeat the operation and to wait from a year and a-half to two years before moderate sight was attained. In the present case the effect was equally slow of attainment, but it had been already almost secured, and I don't doubt that sight would have been eventually secured if we had had patience to wait. It was the necessity for repeated breakings up of the lens in the endeavour to hasten absorption which caused serious glaucomatic symptoms and the loss of the eye, and I have therefore arrived at the conclusion that the soft cataracts of middle life ought, in deciding the method of operation, to be classed with the hard, amber, senile cataracts, and not with the soft cataracts of childhood, which they resemble in appearance and consistence.

If broken up they will undoubtedly become absorbed sooner or later, as the senile lens will ; but the surgeon who, noting their resemblance to the milky cataract of youth, operates with needle will be doomed to disappointment as regards the period which the absorption will occupy. I would, therefore, in soft cataracts at this age, select an extraction operation in preference, and, if a small section be made, no apprehension need, I think, be felt as to sloughing of the flap or want of union, notwithstanding the cachectic state of the patient. In this case I had every reason to distrust the corneal vitality, in consequence of the emaciated condition of the patient and the serious faults of the assimilative system, and these apprehensions were increased by the experience I had had of the low power of the absorbent system ; nevertheless, the section of cornea I made in both eyes closed by first intention with perfect readiness, and as I would have expected them to heal in a young and healthy patient. I draw one final lesson from the case, to wit, the danger of discissions of the lens repeated within short intervals, and the necessity of avoiding any operative method which may render necessary such interference with the eye. In this case the iris was not touched or the lens displaced, nor were any fragments allowed to fall without the capsule, and yet a glaucoma resulted, which, I fear, must have been without doubt due to the last and most extensive tearing of the lens substance. My father, Dr. Arthur Jacob, has expressed himself in his book on Cataract as extremely averse to the repeated operations which are recommended by other writers, and he maintained that, while they are attended with considerable danger of producing intra-ocular inflammation, they produced no commensurate effect upon the rate of absorption of the lens. I concur in that opinion, and will in future hesitate to adopt the operation by division in any case in which it may need to be repeated more than three times or at more frequent intervals than three months.

I may epitomise my conclusions from this and other cases of soft cataract in middle life as follows :—

1. I conceive that this form of lens opacity is essentially different in cause and condition from the senile amber cataract of old age, resulting from an imbibition of watery constituents and a consequent swelling up—molecular disintegration and ultimate maceration of the lens substance, while the amber opacity may be the result of an exactly reverse process.

2. I believe that the soft cataract of middle life is usually accompanied with a great depreciation in the power of the absorbent system, probably in every organ, certainly in the eye, and, therefore, that the operation of division, which is so successful in similar cataracts in young persons, is out of place in middle age.

3. I believe that this suspension of absorbent energy, while it has its effect upon the general nutrition of the body, does not materially prejudice the chances of union, which form so important an element in the extraction operation of old age.

4. I believe that frequent repetitions of discission operations are liable to produce serious effects on the other structures of the eye, and ought not to be resorted to unless absolutely unavoidable.

THE MODES OF USING CARBOLIC AND SALICYLIC ACIDS IN ANTISEPTIC SURGERY. (a)

By Edward H. Bennett, M.Ch. T.C.D.,
Professor of Surgery in the University of Dublin, and Surgeon to Sir Patrick Dun's Hospital.

In submitting to the Surgical Society of Ireland a paper on the modes of using carbolic and salicylic acids in antiseptic surgery, I need not enter into any discussion on the theory of their action, for all that we know on this matter is no doubt familiar to its members. I do not, either, in selecting these two antiseptics, deny the merits of others—boracic acid, chloral, benzoic acid, &c. I simply deal with these for, with the exception of boracic acid, they are the only antiseptics suitable for dressings, of which I have had sufficient experience in practice to enable me to form a judgment. The value and efficiency of carbolic acid is admitted by all who have tried it with proper care, and I think we might well rest satisfied with it, but for some trivial objections which can be raised against it, and because in some rare cases it is liable to fail, and even to do harm. On salicylic acid very opposite judgments have been passed by high authorities. We find on the one hand that Theirsch regards the antiseptic action of salicylic acid as being as certain as that of Lister's carbolic dressing ; on the other hand, Mr. Callender thinks that it does not deserve the commen-

(a) Read before the Surgical Society of Ireland, March 24.

dations it has received. While such differences of opinion exist as to matters of fact I need not apologise for stating my opinion, founded on a fair trial of the remedy. I can most readily discuss this question by first stating the objections to carbolic acid, as I have heard them advanced, or observed them in practice, and afterwards stating the advantages of salicylic acid, and my experience of it. I may say that the only mode of treatment by carbolic acid that I have had extensive and successful experience of is that with Lister's gauze and the spray. I had tried some of the older methods, but with but small success, before I had the advantage of the personal teaching of Mr. Lister, for the benefit of which I cannot sufficiently thank him. Indeed, so little success had I with the earlier methods, I had almost decided against the treatment; but fortunately I waited to see it carried out by its inventor, and I could not refuse the evidence of the cases which I saw in his wards. I saw, too, that all my own failures were due to my neglect of care in carrying out the details of the treatment.

I think the objections I have noticed above may be considered under the two heads trivial and actual.

The trivial are that the treatment is (1) troublesome, (2) expensive, (3) disagreeable.

By the first I mean troublesome to the surgeon, an objection that should have little weight, even if it were true in fact that there is an extra amount of trouble entailed by this treatment. I do not think there is any more real trouble, except the learning of a method which demands scrupulous attention to detail. I think that in cases involving life the question of the trouble the surgeon may be put to cannot be entertained if he be assured that the danger to the life of his patient may be even in the least diminished. In cases that under any treatment would terminate favourably the patient would certainly, if allowed the choice, select the antiseptic, for the sake of the immunity to pain which its successful practice carries with it.

2. The objection on the score of expense is not worth serious consideration, for although the first few dressings may appear costly, the long intervals that follow between the subsequent dressings and the absolutely diminished total of expenditure attending a shortened treatment fully compensate for an early outlay.

3. The third trivial objection—that the treatment is disagreeable. I may remark that I have not heard it advanced by surgeons except by those who are determined to object to it on any or every score. By patients I have never heard the objection raised, even by the most ignorant and irritable, after the smallest experience of the practice. The only disagreeable result of the gauze treatment that I have heard patients complain of is that the gauze on some skins seems to be irritating by its roughness. This I hope to show we may avoid.

Before considering the actual objections, I may say that, although I regard those I have mentioned as trivial, still I think we may seek to meet some of them—to diminish the frequency of dressings, to avoid, as I have said, the irritation caused by a rough gauze, and in a great measure, too, to diminish the expense.

The objections which come under the second head are those to which the most serious attention must be paid.

The first of these is that the treatment is liable to failure from different causes—want of due attention to details on the surgeon's part, the adoption of the treatment in ignorance of the cases to which it is inapplicable, and lastly, from causes purely accidental and beyond the surgeons control—namely, unexpected discharges of serum, of blood, or purulent fluid to such an extent and quantity as to saturate and flow freely beyond the dressings. Now these dangers can only be met by care, knowledge of the limits of the power of the treatment, and by adopting measures to guard against the accidents named. The last precautions are, I think, to be found in the adoption of early and repeated dressings, and, to some extent by the adoption of salicylic acid in aid of carbolic, as I shall presently show.

I have said that carbolic acid used in the treatment of certain cases appears to be injurious. I have seen it in a single instance, used in the ordinary manner, provoke a violent attack of eczema, which required many weeks of treatment before recovery. I do not know how to guard against this accident, for, as I have said, I have but once seen it, and I do not think that any character of the case could serve as a warning. Again, I have, I think, seen cases of burn, which at first behaved kindly under its action, stop short, and fail to progress towards cure until it was discontinued. Again, there are certain cases in which the acid, although not actually injurious, is not, in my experience, the best treatment—namely, cases of lupoid ulceration. On these I think it exercises no action beyond the control of their odours.

Before passing on to consider the use of salicylic acid, I must notice an objection which I have heard put forward against the use of antiseptic treatment generally, which I hardly know how to name—it certainly is neither trivial nor actual—namely, the statement that wounds thrive best under an atmosphere saturated with their own stench, being stimulated to a more rapid cure thereby. Those who hold this opinion may please themselves by finding a name for it.

The volatility of carbolic acid, while it is one of its greatest virtues, is certainly one of the causes that render it liable to fail as an antiseptic. It is this property that renders its spray so complete in its action, and renders the action of the acid so universal in a wound, particularly a wound presenting deep recesses. But its volatility renders its retention in the dressings, and in accidental overflows of the discharge beyond the dressings, difficult. Hence the necessity of frequent dressings, and of the removal of dressings at whose borders discharge appears, for if this be not done, decomposition may readily spread inwards to the wound. Compared with carbolic acid, salicylic is non-volatile, and it is very feebly soluble in water; hence its spray is defective, and it certainly does not extend its action to the deep recesses of a wound as vapour; it is therefore less penetrating as an antiseptic, although its action is sufficiently powerful in solutions. I think its special advantage is that while being non-volatile, and but feebly soluble, its feeblest solution is highly antiseptic; it is, therefore, when used with carbolic dressings, capable of compensating the defect of the carbolic acid by saturating discharges as they flow through the dressings and perventing their decomposition for a great length of time. I have tested such discharges, collected from the margin of dressings through which they had flowed during some hours, so as to moisten a sheet, folded eight times beneath the patient, through and through. The most remote stain of discharge gave the characteristic colour with perchloride of iron; the sheet was perfectly free of odour, and, lastly, the fluid collected as it dropped from the margin of the dressing at its lowest point, after the amount above mentioned had already escaped, gave the reaction, and when kept in a bottle with free access to the air, dust only excluded, no putrefactive change occurred until one month had elapsed. These results were obtained in a case which I think tested every point of the antiseptic treatment, but without failure following, and I repeated the experiments many times.

Such are the chief advantages of the salicylic acid. I agree, after a very careful and sufficient trial of it, with the statement of Theirsch that it is un-irritating in solutions or dressings containing a sufficient amount to effect all the purposes of the treatment. Mr. Callender has arrived at an opposite conclusion, stating that it has caused in his hands extreme irritation. I have not found it produce such in any instance but one, and there clearly the irritation was due, not to the acid, but to the mode of using it—a mode which ensured the retention of discharges in the wound, and consequently tension similar to that produced under a scab.

In the face of these facts I am forced to conclude that Mr. Callender has produced the irritation he complains of

by the mode of his dressing, and by the substance combined with the acid, not by its own action.

I have found that the salicylic acid dressings did not exert so marked an influence in controlling suppuration as carbolic acid, a point which Mr. Callender has also observed, which I think is to a great measure due to the fact that it is non-volatile, and so does not penetrate the depth of wounds. It wants, too, the advantages that arise from the stimulating action of the carbolic acid, and so I think wounds progress rather more slowly under its action.

The spray of salicylic acid, though entirely odourless, is quite unfit for general use, as no one can resist a constant tendency to sneeze while exposed to it.

I have, with the exceptions I have noted, obtained a great number of completely successful results with salicylic acid alone, and do not hesitate to use it by itself in many cases—for instance, in the treatment of burns.

I have, however, been led up gradually to a plan of dressing which combines both acids, and for the reasons I have stated above. I had used carbolic with constant success, and was not inclined to change it for any other without good reason; so it happened that while I made some trials with salicylic acid in minor cases I used the carbolic alone in the more important—a plan that naturally led me to combine them as soon as I found out their particular merits.

Every one knows the antiseptic gauze, by appearance at least, so I need not describe it. I will merely state that one of the greatest difficulties I find in practice is to obtain a reliable gauze in this city; either it is old and has lost its charge of acid in great measure, or it is badly made. It can be made, buying everything at retail prices in small quantities, at less than 5d. a yard; and sooner than rely on Dublin manufacture, as I have found it, or pay 7d. a yard for Scotch, I make my own—no doubt a process involving some little trouble, but after all but very little.

The salicylic dressing I have found most convenient is that recommended by Theirsch, made by saturating jute with the acid, 3 per cent. by weight, adding a little glycerine, 4ʒ—1lb., which prevents the drying of the jute. I should mention that I think great advantage attaches to this moist condition of the dressing—it is ready to absorb moisture, and if air be drawn through it, as in wounds affected by respiration, the moist threads serve, I am confident, as better filters than dry ones would. The advantage of addition of glycerine, according to Theirsch, is that it prevents the dry acid flying off in dust from the jute. I have used the cotton-dressing, too, but I keep it only for cases of burn or such surfaces, and I take care to avoid the tendency it has to form scabs on the surface, which alone is the cause of irritation, as I have seen it occur in the use of the acid.

Nothing can be easier made or more readily applied than the jute dressing. I apply it beneath a few folds, generally three, of gauze, containing sheet gutta-percha, directly on the wound, except in cases where the support of a bandage is required directly on the flaps, &c. This mode of application made under the carbolic spray combines both acids, and the application of the jute next the wound prevents the irritation often felt from the gauze rubbing the skin.

The cost of this dressing is, I am confident, less than even the old poultices, for while they required many changes a day, this may be left many days unchanged when discharge is moderate. The jute costs (Manilla bars, as it is named) 3d. per lb., and this pound will dress a great number of cases.

The shortness of the time at my command in reading a paper before this Society prevents my giving the details of cases illustrating the points dwelt on in the foregoing remarks. I may however state of the newer remedy, salicylic acid, that I have tested its merits in a wide range of cases, minor amputations, gunshot injuries, burns, abscesses of many kinds, acute, symptomatic, and encysted, excision of the eyeball, ulcers of the leg, lupoid ulcerations, empyæma, &c. Carbolic acid I have applied in almost every class of case.

ON A CASE OF CONCEALED ACCIDENTAL HÆMORRHAGE. (a)

By J. Ashburton Thompson,

Fellow of the Obstetrical Society of London; Surgeon-Accoucheur to the Royal Maternity Charity; Surgeon at King's Cross to the Great Northern Railway Company.

(*Continued from page* 25).

I have now passed in review those symptoms which are either constant, or which, while they are admittedly very frequent, their cause renders probable are constant, but have in the confusion naturally attendant upon such rare, obscure, and alarming cases, been sometimes overlooked. I now arrive at symptoms which are not constant and not essential. The first of these is continuous tenseness of the membranes; that is to say that they feel between the throes just as the bag of waters generally feels during a throe in an ordinary case; while during a throe little or no difference in the tension can be detected. This symptom is noted but five times in my series of thirty-three; and Dr. Goodell remarks of it, that although some writers have contended that it should always be present, yet it was actually observed but eight times in his hundred and six cases. In eleven of my cases no note is made as to the state of the membranes; in three they were found ruptured on the first examination; in one they were found flaccid—a case to which I will again refer. There are therefore eighteen cases left, of which five—or about 27·8 per cent.—afforded tenseness of the membranes. I quite agree with those writers to whom Dr. Goodell refers, in thinking that this symptom should and might be observed more frequently than is the case; but not invariably, for a reason which the case I have just referred to (in which the membranes were flaccid) illustrates. Indeed, if the five examples which I offer be examined, it will he found that they include all those in my series which occurred under the hands of specially skilled observers—of persons specially prepared to note all the symptoms from a previous knowledge of them; and *vice versa*, wherever a case in my list has been under the care of such an accoucheur, this symptom has been noted. Dr. Hicks' own case must be excepted, for he found the membranes ruptured on examination. But Dr. Goodell found the membranes tense in his case; so did Dr. Brunton in his first case, his second case, and in his fourth case. In his third case the hæmorrhage was more properly accidental hæmorrhage, concealed only by the position of the child's head in the pelvis; while in his fifth the membranes were already ruptured. So in my own case. Having the advantage of working in concert with Dr. Brunton, I was, I confess, much better prepared to make observations in the kind of case than I otherwise might have been—very fortunately for the patient; and I did at once observe uniform tenseness of the membranes. Hence I think that this symptom ought to be observed somewhat frequently. If the membranes are ruptured, that, of course, precludes the possibility; but there is another circumstance which prevents this symptom from showing itself. In Case 7 the membranes are particularly noted to have been flaccid. It was under the care of Dr. Oldham. The effusion was not small in quantity, but the solid clot was small—and it is that which causes the symptoms, and which is poured out before the ovum is otherwise disturbed. That is not the reason, however, that the membranes were not found tense. What was the state of the placenta upon examination? It was found hollowed out, condensed, *cupped* by the hæmorrhage; that is to say, the case was one of those in which the hæmorrhage is en-

(a) Read before the Harveian Society of London.

tirely retained between the placenta and the uterine wall. Thus, if the placental detachment be a central detachment, and the hæmorrhage confined by the edges of the organ, the membranes will not be found tense. If the eighteen cases in which note of the membranes was made, and of which I stated 27·8 per cent. offered tense membranes be again examined with regard to this point, it will be found that in ten of them the placenta was either entirely attached by its rim and hollowed, or only detached to a very small extent and flattened. Hence, expertness and knowledge apart, the membranes were but seldom found to be tense, for a definite reason.

Persistence of this tenseness between the throes I have set down as a fifth symptom of this condition. It is a necessary consequence of the manner in which it is caused in the five cases noted; but it is, I believe, a pathognomonic symptom, and as such entitled to a separate place in the list. This condition affords yet another sign by which an obscure case may be distinguished from one of laceration of the uterus; for although that accident may happen before labour, and therefore while the ovum is entire, I have not yet met in the course of a rather long search with one case of rupture in which, upon examination, the membranes *remained* entire. The uterus, when it breaks spontaneously before labour sets in, does so from a sudden and violent contraction, which may be excited by any mental emotion; and the fact of its being filled with fluid which cannot escape (for the os is still closed) submits its walls to a hydrostatic pressure which they cannot withstand. But I do not know that the membranes ever, after rupture in this or any other way, remain entire; and that in a doubtful case should serve to exclude rupture from our diagnosis.

The sixth symptom to which I wish to direct your attention is alteration in the uterine tumour in shape, size, or quality. It is liable to be altered in shape very distinctly when the placental detachment is central. In that case the distension of the uterine wall gives rise to a tumour which may be felt to project distinctly from one side of the uterus. Such was the case in Case 18, in which it is said the tumour was extremely tender, and became harder during a pain. The placenta was found to be basin-shaped, and to contain a large recent clot. In this instance Dr. Priestley, under whose care the case was, suspected that the uterus was ruptured, and that the tumour might be a part of the fœtus protruding through the rent, so much did the symptoms resemble those of that injury. This kind of swelling is seldom recorded. Very often the uterus is said to have been distended at the fundus—eight times out of thirteen in which anything is said about the shape of the uterus. Together with this alteration it becomes altered in consistency, the alteration being towards hardness. In one case, indeed, it is said, though enormously distended, to have felt "doughy." The following sentences are the author's own:—"The abdomen was very tense, the uterus feeling doughy, being distended to the utmost." I do not know what to make of that description. All these alterations are quite incompatible with rupture of the uterus. In that injury the organ does not increase in size, nor does it alter from the normal in its consistency. It is subject to the same alternations of hardness and relaxation which are observed under ordinary conditions of labour, unless, indeed, the throes should entirely cease, in which case the uterus is not hard, of course, but soft. So in the case of the local swelling; if the abdominal walls be thin enough to allow of a thorough palpation of it, then the absence of any part of the fœtus in it affords the best evidence that that is still within the uterus. But its alternate hardening and relaxation must evidently be owing to uterine tissue still stretched over the tumour; and its tenderness—which will be observed at every part—show that it is not a gap allowing of the protrusion of a body not sensitive, but that it is a swelling of some part of the mother, who cries out when it is touched—that is, of the uterus.

Lastly comes tenderness of the uterus, upon which I have already remarked. This will be felt, unless the hæmorrhage be circumscribed, as in the case last described, over the whole uterus. In considering this symptom with regard to rupture, it will be remembered that in the kind of case I am considering the cause of pain is seated within the uterus, and is there confined to it; while in rupture its cavity communicates with the abdomen, in the whole of which it is not uncommon to find pain complained of, while the uterus itself yields none.

To these symptoms one or two others might be added. If the placenta be largely separated the fœtus must die. But the recorded cases throw no light upon the diminution of the placental murmur and cessation of the fœtal pulsations which would result. Dr. Goodell has suggested that in such cases as those in which the membranes remain unruptured some aid to diagnosis might be gained from a discharge of serum squeezed from the clot effused; for the serum will penetrate where the blood itself will not. He observed this symptom himself; but I do not know that it has been put to any practical use by any other person.

I have thus gone over the symptoms of concealed accidental hæmorrhage with a view of showing in what degree of frequency they may be expected to arise. And I believe I have made out that, while sudden syncope and collapse, feeble or absent throes, and continuous pain are constant symptoms, that persistent tenseness of the membranes may be expected to show itself, except under certain well defined conditions of the mode of hæmorrhage; while alteration in the abdominal tumour is a still less frequent symptom, which, though it may sometimes occasion some difficulty in diagnosis, does on the other hand sometimes afford a means whereby this accident may unerringly be distinguished from any other; and that it may be expected to offer its assistance pretty frequently.

To recapitulate. I would propose to describe concealed accidental hæmorrhage as a uterine hæmorrhage occurring only during pregnancy; arising before labour; sometimes entirely confined between the placenta and the uterus, generally entirely confined by the uterus, but occasionally attended by a little external hæmorrhage; and, irrespective of its amount, suddenly threatening life from shock to the system. To this I would add that accidental hæmorrhage is properly considered to be *concealed*, notwithstanding there may be some external show, whenever the symptoms are such as the amount of the latter does not serve to account for. Its symptoms are and arise as follows: The patient being at, but more often only near, the full term of pregnancy, experiences some shock, such as would usually cause separation of the placenta and accidental hæmorrhage of the ordinary kind. For instance, she makes some sudden or violent or unaccustomed use of her muscles; as when stumbling or slipping in walking, or by dancing, by pumping, hewing wood, suddenly lifting a heavy weight, or coughing, or from mental emotion. Upon some such occasion she becomes suddenly faint. From such faintness she may recover to succumb to a second attack in a day or two. More often the fainting is prolonged; she experiences an uneasy sensation in the abdomen, and shortly passes into collapse. She is now in danger of speedy death, yet she is seldom unconscious. The sensation of uneasiness becomes a sensation of constant pain, which she refers to the uterus, but sometimes to other parts as well; she will very likely describe it as a bursting pain, and will always regard it as intolerable, either from its continuousness or from its severity. Meantime there is no sign of labour. On examining the abdomen the uterus may be found enlarged; but in any case it will be found hardened, well defined, and incompressible; in addition, it will be tender. A vaginal examination may still find the os uteri closed; but after a time it dilates a little, and may then be perceived soft and easily dilatable to its full extent. Feeble throes will supervene; but although they will cause excruciating pain, have but the slightest effect upon the membranes. These are often found continuously tense, in correspondence with the tenseness of the uterus itself, and with the constant pain. If now—at a favourable time with regard to the state of the os—the membranes be ruptured, the pains

will at once gain in force, and the os will dilate and allow the passage of the fœtal head with suprising rapidity. Delivery of the child will be immediately followed by a large quantity of blood, both fluid and clotted. The latter was the first effused, and was the cause of the symptoms; the former was poured out, possibly at an early stage also; but, generally, as soon as the ovum is disturbed by the rupture of its membranes and the passage of the child towards the world; sometimes immediately subsequent to its birth. On examination the placenta may be found compressed at its centre—cup-shaped, or compressed or condensed at some parts only, from the pressure to which the earlier effusions have subjected it; but it is not always affected in that way. Subsequent to delivery the patient is in increased danger of death; if she were not completely collapsed before, she now becomes so; if she were already collapsed, she suffers yet a farther shock in the rapid evacuation of her over-distended uterus; and she is very likely to die of a comparatively trifling farther hæmorrhage. About half of the hitherto recorded cases of accidental concealed hæmorrhage have terminated fatally.

It will be at once apparent from the statement last made that the treatment of these cases is a most important matter; except under proper management there is but little chance of escape for the subject of this accident. Dr. Hicks, in discussing it, observes that no doubt that treatment which is proper to ordinary accidental hæmorrhage is proper to concealed hæmorrhage; but, he adds, "how far the particular part of that treatment, namely, rupture of the membranes can be relied on, cannot be gathered by the details now before us, for in them we find that in nearly the whole of those that died the membranes had been ruptured. Whether any of the seven who recovered would have died had it not been done it is impossible to tell." Well, this point of rupturing the membranes is the only point almost on which the accoucheur can actively interfere, and it is that, therefore, with which I shall chiefly concern myself. But I do not propose to examine this question statistically. In a case of this kind such a mode is useless, as Dr. Hicks himself shows. I shall therefore discuss it on general principles. Our object should be to *evacuate the uterus as speedily as possible;* and in the best way of doing this rupture of the membranes is involved. To over-distension of the uterus the grave primary symptoms—which include paralysis of the uterine walls from that cause—are owing; how far may we fairly expect to relieve them by relieving their cause? What effect in permitting uterine action to a uterus paralysed by over-distension has the relief to it which discharge of the waters effects? What danger is there in discharging the waters, in breaking up the ovum—of dislodging such clot as may be occluding the gaping uterine sinuses? These and similar questions are those which will at once suggest themselves in undertaking the treatment of a case of concealed hæmorrhage; it will be well to have answered them already, and to be prepared to act at once upon the emergency.

On the whole, the treatment proposed by Dr. Hicks is not laid down in any very precise manner, beyond the assertion that the indication is to empty the uterus. It is, however, stated plainly enough that, since rupture of the membranes tends to hasten labour, they should *always be ruptured at once*, if they are not already broken; but should the patient be completely collapsed, it will be better, *after rupturing the membranes*, to administer stimulants and wait a little, than to empty the uterus immediately, supposing the state of the os to admit of that being done. From this practice, inculcated in these general terms, Dr. Brunton dissents, on the ground that rupture of the membranes does not always tend to expedite labour. And unless the os uteri be either fully dilated or else very nearly dilated, and with the head pressing well down upon it, there is no doubt that rupture of the membranes does retard the first stages of labour. Dr. Brunton then proceeds to point out that, to some extent, at all events, the amount of hæmorrhage must be controlled by the presence of the entire ovum within the uterus; and that it is worse than useless to dislodge this natural plug by evacuating the liquor amnii, unless the *whole* of the ovum can be removed at the same time. To this it may be added that, more precisely speaking, this danger is special to this kind of hæmorrhage. For, in revealed accidental hæmorrhage rupture of the membranes permits the uterus to contract, and so lessens the area of the bleeding surface very speedily. But frequently the hæmorrhage in these cases is entirely confined by the adherent edge of the placenta; and in that case to remove the support which the entire ovum affords would be but to permit a farther bulging of the placenta inwards—that is, a farther hæmorrhage and a more profound collapse. Now, in dealing with a case of this kind, what I have before stated with regard to the absence of uterine contractions will be remembered; that it is in part owing to over distension, but in a measure—and probably in a great measure, to the collapse. Our first step should therefore be to remedy the collapse; and in whatever danger the patient may be—however imminent death may appear—I think that on the one hand we shall not be wrong in considering that danger due to things which *have* happened, not, that is, to hæmorrhage which is continuing; while, on the other, we must not forget that in these cases "more haste less speed" is a proverb very applicable; that the evacuation of the uterus if effected will be thorough and complete, fœtus, placenta, and hæmorrhage coming away together, and the patient therefore being exposed to a fresh source of depression, of which, as I have shown, she is now particularly susceptible. Supposing, then, that the membranes be found unruptured, and the os uteri moderately dilated, the patient being collapsed and all uterine contraction, of course, absent. I should under these circumstances be inclined, in the first place, to administer stimulants, which should include food of some kind; and in order to produce a rapid effect, the intravenous injection of ammonia might perhaps, notwithstanding its effect in lessening coagulability of the blood, be useful. To this an irritant applied to the præcordium, may be added; and on account of the immediate effect upon the heart's action which raw spirit has in passing down the œsophagus, that too should be given. At all events, whatever means be employed, a reasonable time may be spent, in the first place, in combating the collapse. Next, the abdomen should be encircled by a bandage, which should not be fixed, but left so that one end may be pulled tight as occasion demands—the attendant's knee at once fixing the nethermost end of it and the patient's loins. Thirdly, the patient should be so arranged that the head *and heart* are decidedly below the level of the rest of the body. It will now be time to consider whether or no the membranes should be ruptured. Here it should be remembered that in many cases in which the os was upon examination only partially dilated labour was very rapidly completed upon rupture of the membranes; the collapse had favoured its passive dilatation. Therefore, if there be the least sign of recurrent throes, the liquor amnii may be discharged, and the bandage tightened. But, should the throes not supervene, and the patient's condition become worse, as it certainly will until she is delivered, the forceps (already at hand) must be applied; and, in using them, the ease with which the os may be dilated in these cases may be borne in mind. Extraction being nearly completed, it will be remembered that the uterus in contracting has by this entirely separated the placenta, and the hand should therefore supplant the bandage, which, while the uterus was well distended, gave support enough. Upon the exit of the child firm pressure to the uterus should be continued, and the placenta, with a greater or less amount of discharge, will follow at once. The attendants should at once remove the child, so that the accoucheur is left entirely free to control the uterus and to minister to the patient, who will now demand his entire and unremitting attention.

But it is noted in many cases that the os remained closed after the accession of alarming symptoms; and of those cases, all those who died, died undelivered. In a word, the longer treatment is delayed, the worse will become the patient's condition; hence, with a view of rendering an early diagnosis more easy, I have discussed the symptoms as above, separataly, and at length. In this case the os must be forcibly dilated, and that speedily; and for the purpose no better means is at hand than Barnes' dilating bags. But for reasons already given, they should be so applied, if possible, as to preserve the membranes entire until the right moment comes for emptying them. I do not know of any case in which they have been used, but, from what has already been stated, it might be expected that the os would yield pretty rapidly.

I have thus far purposely omitted mention of the use of ergot, because it involves a discussion of the comparative merits of version and extraction by the forceps in cases in which the uterus fails to take on action. Dr. Goodell, in discussing the latter point, places the two methods of delivery on a par as regards time, for the following reasons:—That if version be undertaken, probably the whole hand must be passed into the uterus, because the clot and bulging placenta will form a ledge such as would prevent the use of the bi-polar method; and, if the hand can be introduced, so, most often, can the forceps be applied. For my own part, while agreeing in this view, I should be very averse to turning the child unless it were found impracticable to deliver in any other way; for that ledge which would obviate the effect of the small force applicable by the bi-polar method would give way under the greater force used in the ordinary manner; that is, that very disturbance of the clot and placenta would be effected while the uterus was still unemptied which I should, up to that time, have preserved the membranes entire especially to prevent. Of course, in a case of this kind, in which speedy delivery is the object in view, it must first be ascertained that the pelvis is roomy. If it be contracted, even with great dexterity considerable delay may occur in extracting the head, during which, from the paralysed condition of the uterus, there will be great risk of further hæmorrhage. It is a question, therefore, whether in all but exceptional cases it will not be better to drag the cranium within reach by the forceps, and then, if there be any delay in extraction, to at once lessen its diameter by craniotomy. The convenience of this plan is all that need be considered; for almost invariably the fœtus will be already dead. Upon this view, I should not hesitate to give in the first place a large dose of ergot, which, if it do not operate before delivery has been effected (as is very likely under the condition of collapse) will have a favourable effect upon the uterus after delivery.

Should the membranes be found ruptured on the first examination, then the steps to effect delivery above described may be at once taken.

To recapitulate the treatment of accidental concealed hæmorrhage: A short time should be spent in combating collapse, because the absence of uterine contraction is chiefly owing to it, and because the patient requires to be fitted as far as may be for the further shock she will sustain upon complete evacuation of her uterus. The membranes are to be ruptured at a time to be fixed in each particular case; for, they are ruptured in order to facilitate delivery; and this will not be effected if they are broken before the os is pretty well dilated—but on the contrary delivery will be delayed—and the support which the whole ovum affords the partly detached placenta and effused clot at the same time lost. Nevertheless in these cases they may be ruptured earlier than they should be in a normal labour, because the depression is favourable to dilatability. If the attendant have decided in favour of version, then he will not give ergot until that operation be nearly completed; but the use of the forceps, supplemented (if necessary) by craniotomy is to be preferred, because in that way there is less chance of disturbing such clot as may be closing some of the uterine sinuses. And in that case he will have begun by giving a good dose of ergot, not only with a view of exciting the uterus to contract before delivery, but with a view of keeping up its contractions after delivery. He will also in the first place have got the patient in the position most favourable to continuing the action of a feeble heart. Subsequent to delivery he will be prepared to give his sole and undivided attention to the patient, who is not only now liable to sink under a very small further hæmorrhage, but is sure to become collapsed if that condition have not already supervened. And lastly, because she can stand but a little more loss, he will first of all have made arrangements for injecting that most certain styptic in post-partum hæmorrhage—the perchloride of iron, by means of which that case may be brought to a favourable end which without it would probably have terminated fatally.

Clinical Records.

A CASE OF ACONITE POISONING. (a)

Under the care of Dr. G. F. SCHREIBER, West Brooklyn.

I WAS called in haste, June 18th, 1874, to see E. B., a labourer, aged 36 years, who had taken two teaspoonfuls of tr. aconite root an hour before, 9 a. m. He had taken it, he said, to overcome the nervousness and insomnia consequent upon a drunken spree. He was having convulsive attacks, coming on at short intervals; had vomited some, and complained of dryness of the throat, coldness and tingling of the extremities, and muscular weakness. The pulse was almost imperceptible, countenance pale and pinched, and skin shriveled and covered with cold, clammy perspiration. I ordered a draught of warm water and mustard, which produced emesis; the matter vomited had the odour of aconite quite strong.

I sent for Dr. R. M. Lackey, and asked him to bring with him a Kidder's battery. I had hot bricks applied to the extremities, and body as well, and directed the occasional use of friction with dry warm flannel. While awaiting the arrival of counsel and the battery, he had another vomiting spell, after which he fell back in a state of muscular rigidity, eyes staring, respiration suspended, and to all appearance about to expire. Just then the doctor arrived with the battery, which was hastily set going, and one pole applied to the nape of the neck and the other over the region of the heart. He was at once relieved of the spasm, respiration became more regular, and he complained of pain from the current. He begged to be allowed to sleep, which was denied him, and he was kept well roused up by the frequent use of the current, interrupted in such a way as to produce considerable shocks.

At 12 o'clock m. the pulse was slightly perceptible, and he was more sensitive to the current. An enema of warm water and salt was administered, and a copious fluid evacuation was produced, having the odour of aconite. In making another attempt to raise up he again fell back and seemed about to expire, when a good, lively shock from the battery started him to breathing again. Improvement from this time was decided, so that by 3 p.m. he was regarded as out of danger. He slept well the following night and was up the next day, but complained of tenderness over the stomach. No after-treatment was required, as his nervousness had disappeared, and he recuperated rapidly.

The treatment in this case, as will be seen, was mainly by the faradic current, which seemed to counteract the tendency of the poison to produce paralysis of the heart.

The point of greatest interest in the case is the fact that the patient has never tasted a drop of intoxicating drink

(a) Reported in the *Medical and Surgical Reporter*, Philadelphia.

since, and from being a confirmed drunkard and generally worthless fellow, has become a sober, industrious man; and this is the greatest and most decided curative effect I have yet observed from the internal use of aconite.

Transactions of Societies.

SURGICAL SOCIETY OF IRELAND.

THE eighth meeting of the session was held on Friday evening, March 24, 1876, Mr. EDWARD HAMILTON, President of the College, in the chair.

MEDULLARY SARCOMA.

Mr. H. G. CROLY exhibited a specimen of medullary sarcoma of the testicle. The patient from whom the specimen was taken was a man 40 years of age, and was admitted within the past fortnight into the City of Dublin Hospital. The right testicle was of very considerable size, and as far as could be ascertained from the history of the case had been six months growing. According to the statement of the patient, he had received no injury whatever. The tumour presented the usual appearance of these malignant growths of the testis —flattened sides, deceptive fluctuating feel, and was enormously heavy in proportion to its size. There was no thickening of the spermatic cord, and as far as he (Mr. Croly) could discover, no enlargement of the glands, either in the lumbar region, groin, or pelvis. In order to make himself satisfied as to the nature of the tumour, finding it fluctuating, he punctured it, and drew off 2 oz. of hydrocele fluid. As that did not make any difference in the size of the tumour, he then plunged a trochar into the substance of it, and nothing came out but blood. Before the tumour was cut into, it presented the kidney-shaped appearance, and on making a section it resembled brain. It was a well-marked example of *fungus hematodes*, or what was known at the present day as "medullary sarcoma." Dr. Barker, the curator of the museum, had kindly made a microscopical examination of the specimen, and he stated that it was a well-marked example of cerebriform cancer. It was magnified with a power of 500 diameters. Mr. Croly also showed another specimen, for the purpose of illustrating the fact that the disease occasionally attacked both testicles. The second specimen was removed from the body of a young man under his care in hospital.

ENCHONDROMA.

Mr. W. I. WHEELER exhibited the third or ring-finger of a girl which he had removed on Thursday week. The cast which he also exhibited showed the condition of the finger on the admission of the patient. The patient was 17 years of age, and about nine years since a door slammed on the finger, and two years afterwards a tumour commenced to grow—that was the tumour which implicated the second and third phalanges. Another tumour—at the first phalanx—commenced to grow a few months afterwards, and these tumours gradually increased until they attained their present size. The larger tumour is about the size of a walnut, and the smaller one about the size of a hazel-nut. The patient complained of considerable pain, and was unable to use her hand, and consequently —although the tumours were on her right hand—her left hand and arm were very much more developed. On examining the tumours they proved to be enchondromatous, and were elastic to the touch, and on cutting into the larger one it had rather a crisp feel, and the skin expanded for the purpose of its accommodation, but the skin was by no means contaminated by the tumour itself. He asked the curator of the museum, Dr. Barker, to examine these tumours microscopically, and he had stated that the large one was a specimen of simple enchondroma, full of cartilage-like irregular cells, with communicating thread-like connections. It appeared to him (Mr. Wheeler) to have been developed from connective tissue. It was not attached to the bone. There was no plate of bone connected with it. The small tumour commenced in the medullary cavity of the bone, and was of two forms—the hyaloid, and, he might say, mucoid forms of enchondroma, and showed large oval cells and also branched or stellate cells.

Dr. JACOB then read his paper on

SOFT CATARACT OF MIDDLE AGE AND ITS TREATMENT,

which will be found at page 293.

The PRESIDENT said the paper ought not to be passed over without discussion. It was very interesting, taken in a physiological point of view, and also in a pathological point of view as to the peculiar condition of the blood to which Dr. Jacob had alluded.

Mr. TUFNELL said the question of operation for soft cataract against hard by the needle was a most important one, and he thought one that they might well consider. They knew Dr. Jacob's father was a great advocate, and he (Mr. Tufnell) would be very glad to hear the opinions of gentlemen either in support of that view or to the contrary. He had seen the late Dr. Jacob perform case after case; his operations were always successful. But then the late Dr. Jacob had great experience—he did not know how many years—and of course that experience led him to select those cases which were fit for operation, and reject those which were not. The way in which he used to dispose of his cases of cataract was most satisfactory, but then of course it depended upon the selection of cases and the experience of the operator.

Dr. BENNETT then read his paper on

THE USE OF ANTISEPTICS.

which will be found at page 295.

In the succeeding discussion,

The PRESIDENT said that at Steevens' Hospital he had had a large experience in the use of the carbolic acid, but he had not seen the salicylic acid used, and he should therefore be glad to hear the opinions of those who have. There was one point of interest in Dr. Bennett's paper, and it was the combination of the two antiseptics. That plan they had adopted for a long time at Steevens' Hospital, always using the chloride of zinc, and over that carbolic acid dressing, and he thought they were inclined to attach more value—or at least as much—to the careful sponging with chloride of zinc as to the other part of the antiseptic treatment, but they invariably used both.

Mr. TYRRELL said that in the Mater Misericordiæ they used the chloride of zinc and the carbolic acid treatment. They had not used the salicylic acid. He would like to ask Dr. Bennett what were the exact results obtained from the use of this acid? Did it stop or prevent the secretion of pus? Was Dr. Bennett in the habit of obtaining those wonderful results which Professor Lister had spoken of. The Society could not fail to be indebted to Dr. Bennett for the details of this valuable dressing, but it would be interesting to the meeting to know the exact results which Dr. Bennett had obtained.

Professor STOKES was in the same position as Mr. Tyrrell, as regarded the want of experience of the antiseptic action of salicylic acid. For some yeas he (Mr. Stokes) had been oscillating between two antiseptic methods of treatment—one, carbolic acid, and the other, benzoic, using in all instances what the President had mentioned as the custom at Steevens', the application of the chloride of zinc, and after considerable experience he (Mr. Stokes) had adopted the simple plan of the carbolic acid treatment. He had been deterred from using salicylic acid by the observations of Mr. Callender, of St. Bartholomew's Hospital, who spoke strongly in his (Mr. Stokes') hearing against the use of that antiseptic. Therefore he thought it would be desirable that Dr. Bennett should point out what he thought were the advantages of that antiseptic over the others. The treatment which he (Mr. Stokes) adopted in all cases of amputation and similer cases was after the application of the chloride of zinc dressing to use one of a weak solution of the carbolic acid in the proportion of about 1 to 40, with strips of lint, and then placing the stumps on large pads of oakum. He thought oakum was most desirable for use in the after-treatment of wounds. He found it gave most satisfactory results when carbolic acid was used in the weak solution he had mentioned, but it did not give rise to any of the symptoms which Dr. Bennett had spoken of, and which he (Mr. Stokes) had seen produced, but only when the solution was much stronger. That was the treatment he used now, and he saw no reason, after considerable experience, for altering it. He thought all they could desire in treatment was the keeping down of bad odour and keeping everything very clean—all they desired to accomplish was accomplished by that method. He thought it would be of interest if Dr. Bennett would state more distinctly than he had done the distinctive advantages of sali-

cylic acid. For a considerable time he (Mr. Stokes) gave benzoic acid a trial, and found it an agreeable mode of dressing wounds, but it had not so good antiseptic properties as carbolic acid, and therefore he preferred carbolic acid.

Dr. HENRY KENNEDY remarked that salicylic acid had been found useful in affections of the stomach where flatulence and a remarkable disease known as sarcina existed, and was given in the forms of pills and solutions in doses of 2 grains and upwards, as had been stated at a meeting of the Medical Society of the College of Physicians about a month since, when an interesting paper on the uses of salicylic acid was read; the addition of a small quantity of borax made the acid very soluble. It was a useful remedy in those two particular affections of the stomach, and it had also been applied to lupoid ulcers, on which it was stated to have an extraordinary effect.

Mr. W. I. WHEELER said he had used salicylic acid several times in amputations at the City of Dublin Hospital. His former plan was to use the chloride of zinc solution, and afterwards carbolic acid, and he gave up carbolic acid for the purpose of trying the salicylic. His experience of the salicylic acid was this—that it did not prevent suppuration taking place as carbolic acid did, and with chloride of zinc, which he believed to have great antiseptic power, and carbolic acid, he had had very favourable results; but with salicylic acid it appeared to him that more suppuration took place. The great benefit to be derived from salicylic acid—if it really was an advantage—was that there was no unpleasant odour to the patient. As regarded the irritating powers of salicylic acid, he had not experienced that which Mr. Callender had complained of.

Mr. B. W. RICHARDSON (to Mr. Wheeler): You don't mean to convey that carbolic acid stops suppuration altogether?

Mr. WHEELER: No.

Mr. RICHARDSON: Because I don't think it does myself—it may do so.

Mr. WHEELER: I have seen cases of carbolic acid treatment in which there was very little suppuration.

Dr. BENNETT, in reply, said that he thought he might be well pleased with the discussion that had taken place, especially as it gave him an opportunity of remedying the shortcomings of his paper. He thought he had dwelt sufficiently upon the special advantages which he attributed to salicylic acid, but no doubt he had done so but briefly. A slight misunderstanding had evidently occurred, from the observations of the President and Mr. Tyrrell, in supposing that in speaking of salicylic or carbolic acid, he (Dr. Bennett) excluded the chloride of zinc. In the commencement of the paper he omitted to go into details with reference to anything except the dressings, thereby regarding as understood the immediate treatment of a wound—such as an amputation, or, for instance, the removal of a breast, by the chloride of zinc. For himself, he adopted that in many cases, and would do so still in any case where the surfaces were such as to suggest the use of it. No one had thought of applying chloride of zinc in the treatment of a burn of the second degree, with the skin excoriated and stripped of its cuticle. In the treatment of such a case as that, the question of the treatment by chloride of zinc did not arise; but the treatment by salicylic and carbolic acid did. But let them take one case in point in answer to Mr. Tyrrell's question. A burn covering both sides of the gluteal region, the posterior aspects of both thighs, and both legs almost entirely—to cover such a surface as that with gauze—to dress it efficiently with gauze and with carbolic acid, under the carbolic acid spray, was extremely expensive. A very large quantity of gauze would have to be used, and again, they would have to remove it in a very short time, because over so great a surface they could not confine the gauze so as to ensure the carbolic acid remaining in it. A case such as he had mentioned occurred, and he dressed it with salicylic cotton, and the discharge, which was slight, ran through the cotton and was received by the jute which had been banded round. Although vesicles formed, they kept on the use of the combined fluid over the whole gluteal region; the posterior aspects of both thighs and legs being scalded to the second degree, the total number of dressings that case required was only, as far as he could recollect, five. After the first and second dressings they were enabled to let the case go on for over a week without any dressing whatever, and without its being offensive. He did not mean to say that they controlled suppuration; but the suppuration was not offensive, or if offensive, so slight as not to attract notice. That was a case which had been for 24 hours untreated—a man scalded on board ship—and the germs of decomposition in such a surface were destroyed. The salicylic acid in the wool and jute were in that case so perfectly satisfactory as antiseptic dressings that in a short time they were reduced to very wide intervals, and the treatment of the entire case occupied only a month. He did not think they could get a more favourable result by any other treatment. With reference to the special advantages of salicylic acid, he thought the case he had just stated pointed to what they were. He happened to have at present a case under his care which had been under antiseptic treatment—a case of pleural fistula empyema, and which, in order to relieve a condition of hectic, was opened freely. That had been dressed since January constantly antiseptically, and there had never been any odour from it whatsoever since. Before that, however, the odours from it used to reach to the street hall-door in a three-storey house, and rendered the house unbearable to the family. Since the adoption of the antiseptic treatment, however, there had been no odour. The air entered freely into the pleural cavity through the dressings, and they had quite a purulent discharge for over a month without decomposition; whereas in the early part of the treatment it saturated a bed through and through, and they would have had to dress it four, five, or six times a day with the carbolic acid dressing; chloride of zinc could not be applied. The case was previously treated with chloride of lime. He thought the great advantages of a combination of the salicylic and carbolic acids was, because they combined efficiency with a saving in cost, because in a vast number of cases they could leave such a thing as an abscess or an amputation a whole week undressed with perfect safety and without decomposition. After the discharge issued from the surfaces it did no harm, because it was thoroughly saturated with the disinfectant, and could not therefore decompose.

The Society then adjourned.

WEDNESDAY, APRIL 12, 1876.

THE DRAMA *v.* DRINK.

VERY recently we had the last of a series of Conferences in connection with the Church of England Temperance Society. The subject of discussion was "Certain Preventive and Remedial Measures against Intemperance;" and in the course of the evening Mr. Elward Irving, the well-known actor, read an excellent paper, entitled "Amusements," which not only evoked but deserved applause. And although the greater part of the communication was taken up with topics that were rather irrelevant to the main subject, namely, the influence of the drama as a deterrent to alcoholic intemperance, and although he was far from viewing the question in all its aspects, his

remarks were well calculated to arouse the attention of thoughtful minds, and to soften down the prejudices which even now exist among a certain class of the community.

That a man so devoted to his profession as Mr. Irving is should somewhat exaggerate its public utility is not more than we might expect; but we doubt whether the stage can be said to do much in the way of improving the public taste or the public morals. On the contrary, the culture and character of a people would appear to have far more influence over the stage than the stage has over them. It is not so much the stage which dictates to the public as the public to the stage. The scandalous and licentious plays of Wycherley and Congreve would never have been written or acted had they not chimed in with that reaction in the public morals which took place soon after the Restoration. Again, Dryden was by no means a man of vicious habits; but he was driven to write plays in order to live, and to make those plays "pay" he was compelled to prostitute his powerful genius to the depraved taste of the times in which he lived, and to write things of which he was afterwards ashamed.

It is not, however, our intention to consider what moral effect the stage has upon the character, so much as to point out in what way the drama may be able to control in some degree the bad habits and propensities to which most men are inclined.

But with regard to the present question—that of intemperance in the use of alcoholic stimulants—the most we can say is, that the stage can only act as a deterrent to this great vice of English society in so far as it supplies to the public a legitimate amusement, and in so far as amusements in general have a tendency to divert people from pursuits of a criminal or immoral nature. It is evident that if the stage can do any good at all it must do so either by representing on its boards the penalties of drunkenness, or by elevating the taste of the lower classes and weaning them away from the dissipations of the gin-palace and the pot-house, or by acting in common with all other amusements, and distracting for a time the attention of those who, from various causes, have a craving after stimulants of a more questionable nature than that which is afforded by spending an evening at the theatre. The first of these means, however, is impracticable, as the character of a drunkard could only be occasionally represented on the stage. And with regard to the deterrent influence of the drama upon intemperance by improving the taste and morals of a people, there is not much to be expected in that direction. Even if a frequent resort to the theatre did, as we very much doubt, tend to improve the taste and morals of the audience, it does not follow that such an improvement would be accompanied by a dislike to alcoholic indulgences. It is a well-known fact that a man may be fond of the bottle and yet be of irreproachable morals, and have a fine taste as respects all the arts, and habits, and pleasures of life.

But with regard to the *physical* effect of amusements on the mind—of amusements in the largest acceptation of the term—there is much more to be said. And undoubtedly the stage is one of those amusements which is capable of acting as a wholesome stimulant, and a wholesome form of recreation to a mind that is jaded with fatigue, depressed by sorrow, or enervated by *ennui*. This is particularly true as respects the middle and higher classes of society, many members of which have recourse to the use of alcoholic stimulants from the causes we have just mentioned. Everything depends upon the hygienic and moral management of those who are on the verge of becoming dipsomaniacs. To keep the mind constantly occupied with some agreeable study or pursuit, to engage its attention by the cultivation of some liberal art and an indulgence in some liberal taste, and to recreate it and keep it in a healthy tone by a frequent recourse to legitimate pleasures and amusements, must be admitted to be among the best and most efficient remedies that can be adopted by those who are beginning to feel that dreadful propensity to drink with which so many of both sexes have the misfortune to be afflicted. Who amongst us has not had patients who have confessed that their first temptation to acts of intemperance was some overpowering sorrow, some reverse of fortune, some failures or disappointments in life, some sickness of heart from hopes long deferred, some "whips and scorns of time, The oppressor's wrong . . . The pangs of despised love . . . . and the spurns That patient merit of the unworthy takes." And who has not felt how much better it would have been if such patients, instead of giving way to their first temptation, had tried to forget those pleasures of which they were deprived by resorting to those which were still within their reach, by cultivating those sources of enjoyment of which Fortune could not rob them, and, among other diversions, by frequently resorting to that mimic stage of human life where they might have seen, as it were in a mirror, that there are other and more poignant griefs than their own; or where a good hearty laugh might be wrung from faces over which misfortune had cast a melancholy gloom.

In such exceptionable cases—and in such cases only—do we think that a more liberal indulgence in various kinds of amusements can do any good to those who are inclined to give way to intemperate habits. For as respects the lower classes, we cannot expect the vice of intemperance to disappear until the habits and manners of that class have undergone a complete change, until they have become more educated, more provident, and more refined.

THE EARLSWOOD ASYLUM AND CHARITY VOTING.

We are glad to find our leader on "Legislation for the Helpless," of March 1st, has called forth an able document from the Charity Voting Reform Association, and which warmly enters into our views, and dwells upon the evils of the present system of charity voting, as applied to the Earlswood Asylum for Idiots. The document in question has, it appears, been sent to all the subscribers to the institution, and cannot fail to attract proper attention to the very glaring and special evils of the voting and canvassing system in the case of the grievously afflicted class which this charity is intended to relieve. It sets forth somewhat more in extenso anomalies in its working, and which we merely cursorily glanced at, and in a manner that must carry conviction to the more thoughtful among its subscribers. In the spirit of the motto of the institution, "It pleads for those who cannot plead for themselves—the young, the very young," and for whose recovery the earliest attempts should be made. The idiot when

young is undoubtedly susceptible of great improvement, but if this period is allowed to pass before any attempt is made, then his case becomes more hopeless, for the tendency of neglect is, indeed, fatuity ; but if taken early, and carefully trained and educated, on the principle that there is mind, and that it only demands physical manifestation, much, in most cases, that is essential to life, if not all that is desirable, may be secured.

If this be true, as we feel sure it is, then the voting and canvassing system effectually prevents its being carried into effect at Earlswood, for of the 594 inmates, there are only 35 between 7 and 10 years of age, and 122 between 10 and 15, being about one-fourth of the whole. Again, the present list of candidates, 230 in number, enough to last through four years, contains more than half belonging to the pauper class of persons, who are, by the rules of the institution, expressly excluded. Indeed, it is stated "that the benefit of the first efforts shall supply relief chiefly to the middle and poorer classes, and, at the same time, become a model and a motive for improvement in our *pauper institutions.*" The original intention of the founder of Earlswood, it will be seen, has been entirely departed from in regard to the class of candidates admitted, and in favour of paupers from all parts of the country, who ought to be supported and trained by the guardians in Poor-law institutions.

The lower-middle and upper artisan class, for whom Earlswood was specially intended, have thus been shut out to make room for a class for whom provision has been fully made by the law of the land. The poorer portion of the middle classes who are so unfortunate as to have an imbecile child have, in consequence, a great difficulty in obtaining proper care and training for it. This constitutes a real grievance, for they cannot appear as paupers before their boards of guardians to claim the benefit of the legal arrangements made for destitute imbecile children ; neither can they undergo a tedious and expensive canvass, or pay a premium of fifty guineas a year, which the managers of Earlswood Asylum demand of them.

The managers of this—and of all asylums supported by the benevolent—inflict a great hardship upon the class of persons we have alluded to, by refusing help to those for whom it is intended. They should consider, in making a selection between the indigent and those able to contribute something towards the maintenance and education of a child, that the latter more require aid than the former, on the ground that the indigent are already amply provided for ; while for those who are able and willing to contribute there is no provision whatever. Working class families, which under ordinary circumstances are able to pay their way, are liable to be broken down by the burden of an idiot, blind or deaf and dumb child ; and the practical result of this is, that in the majority of cases the child is neglected, and ultimately becomes a permanent charge upon the community.

The lower-middle class with small means, and the well-to-do of the artisan class earning good wages, would, we are sure, be quite ready to contribute according to their means ; they might pay, some £30, some £20, and some £10 per annum ; and, according to the intention of the ounders of the Earlswood Asylum, this class is entitled sk and to have the "first effects" of the institution but the voting system has made all charity paupers alike and the most deserving cases go to the wall in the scramble among 13,000 subscribers, who are pestered and worried out of their lives, and simply because the present system pays. A full experience of the evils attending the voting system, however, proves beyond a doubt that it repels as many subscribers as it attracts ; but apart from this, it is evident to all who have fairly mastered the question that some substitute for the heavy expenses of canvassing for uncertain elections should be found. Small fixed payments by families and friends, in order to secure admission to such asylums as Earlswood, will not only be a perfectly legitimate mode of raising funds, but will allow of a considerable saving being made in the expenses of the institution. In the concluding words of the "Charity Voting Reform Association"—

"Although consistently advocating the alternative of abolishing the voting system, or reforming its abuses, as applicable to the great majority of charitable institutions, we cannot refrain from earnestly suggesting the former as the only course suitable to the Earlswood Asylum, having regard to—

"1st. The necessity for beginning at an early age the remedial treatment of the peculiar affliction which you seek to assuage.

"2nd. The special claims and circumstances of the lower-middle and upper-working class ; and

"3rd. The large number of subscribers and the national character of the institution.

"Actuated by a sincere desire to promote the greater prosperity and usefulness of your important charity, we confidently submit these views to you, in the hope that you may find in them additional reasons for improving the mode of admission to the Earlswood Asylum, and that the result will be that the subscribers themselves will take action in the direction indicated."

Notes on Current Topics.

Conference on the Sanitary Laws.

THIS Conference, at which some important matters will be discussed, is arrnged for the 11th and 12th of May, in the rooms belonging to the Society of Arts. We are enabled to furnish the following programme of the proceedings :—1. Do the existing boundaries of urban and rural districts furnish such a division of the country as enables authorities to exercise their powers and fulfil their obligations, for sanitary and all other purposes of local government, in the most effective manner ? 2. What preliminary inquiries, if any, are necessary to determine the question ? and if, ultimately, districts should be reconstructed ? *a.* What principles should govern their reconstitution ? *b.* How can this reconstitution be best carried into effect ? 3. Should there be more than one authority within the limits of any one of the boundaries so reconstituted, or should area and authority coincide ? and should all authorities be governed by the same sanctions, and be invested with the same powers ? Should new authorities be constituted, and is it desirable to have any intermediate representative local board between sanitary authorities and the Local Government Board ? 4. Are the powers already granted to local sanitary authorities in any respect inadequate to fulfil their intention, and should

all powers and purposes of local government be vested in, and carried out by, one and the same authority? 5. What, if any, alteration should be made in the incidents of taxation for sanitary purposes, so as to insure that payments should as nearly as possible coincide in amount with direct benefits? 6. What officers are essential to good government, and how should they be appointed, regulated, and paid? This Conference will be preceded by one of the Society of Arts "On the Sewage Question."

Duties of Sanitary Officers in Ireland.

On the passing of the Public Health (Ireland) Act two years ago, the Local Government Board made an order under their seal (which will be found at page 512, Irish Medical Directory) defining, as they were authorised to do, the duties of all sanitary officers, including, of course, the medical officers. In accordance with the terms of that order they have recently informed a medical officer who had inquired of them "whether it was part of his duty to attend and give evidence in cases of prosecution under the Sanitary Acts," that "every sanitary officer is required to attend and assist in all proceedings in which his attendance or assistance may be necessary."

If this order were made under due authority of the Act of Parliament, it would without doubt be binding on every dispensary medical officer in Ireland. Indeed, if the sealed order be legal and irrevocable, it is hard to say what the Irish Local Government Board may not order the dispensary medical officer to do. Under the head of "Executive Duties" the order says:—

"1. The duty of the executive sanitary officer shall be to attend every meeting of the sanitary authority, and to take directions on the sanitary business of the Board, and on the reports of the sanitary officers, *and all proceedings arising thereon*, and to see that the same are carried out and brought to a conclusion where practicable, in pursuance of the orders of the Board.

"2. In furtherance whereof we do hereby direct that every sanitary officer and sub-officer of the Union shall, on receiving directions from the executive sanitary officer, attend and assist in all proceedings in which his attendance or assistance may be required."

Is there any act conceivable, professional or unprofessional, which these rules would not demand to be done by a medical officer?

The word "proceedings" in clause 2 must be held to mean the proceedings referred to in clause 1, but the wording is so vague, being purposely made so, that it would include the service of processes or the cleansing of a sewer, or indeed any act which "arises" upon "the sanitary business of the Board, or on the reports of the sanitary officers."

But, fortunately, the Legislature does not seem to have intended to confer upon the Local Government Board an unlimited power of this sort, for it very distinctly set out in the Public Health Act the functions which sanitary officers were bound to discharge, and for the execution of which the Local Government Board might specify detailed instructions. Beyond the limit of these functions no order of the Board can go, and no instruction from them is binding, and we are therefore satisfied that they have no right whatever to require medical officers to attend and give evidence in sanitary prosecutions.

By clause 10 it is enacted (page 487, Irish Medical Directory) that "every medical officer of a dispensary district shall be a sanitary officer for such district, and the said Board (the Local Government) shall assign to the dispensary medical officers, and to the other sanitary officers, if any, and to the medical superintendent officer of health, if such an officer be appointed for the santary district, their respective duties and functions *in the discovery or inspection or removal of nuisances, in the supply of pure water, in the making or repairing of sewers and drains, or in generally superintending the execution of the sanitary laws within the district.*"

This clause, we assert, gives the Local Government Board no authority to compel sanitary officers to attend prosecutions as witnesses, or, if sworn, to give evidence without a fee. The sanitary officer is bound by it to aid in finding out a nuisance, to inspect it when found, and to help in removing it, to look after pure water supply, to superintend the making of sewers, and to "superintend" the execution of the law. The giving of evidence does not come within the term "superintend," nor does the wording of this clause justify the indenfiite imposition of irrelevant functions upon the sanitary officer by the Local Government Board.

We trust the public or our English readers will not misapprehend the nature of our demur. The medical officer of health might be held to be churlish and obstructive in insisting upon the letter of the law being observed if he were paid a salary which might reasonably be considered to cover long journeys, great delays, expert evidence, and unpleasant collisions with his patients. But he is not paid for bearing these *désagréments*, but, on the contrary, is told to be content with the beggarly pittance of £5, £10, or £20 a year, because he has little or nothing to do for the money. The attendance on every prosecution, if enforced, would at once treble his sanitary work, and we are therefore entitled to protest on his behalf against the illegal imposition of such a duty. This being one of the first instances in which the order of the Local Government Board as to duties of sanitary officers has been tested, the Council of the Irish Medical Association has placed the matter in the hands of its law adviser, and has requested his opinion whether they can interpose to protect the sanitary officers from the compulsion under which they are placed to discharge a function which seems to us quite illegal.

Hot-Water Treatment of Uterine Inflammation.

In the Report on Gynæcology to the New Hampshire Medical Society, Dr. W. W. Wilkins strongly recommends the use of hot water in uterine inflammation. Having noticed the effect of very warm water upon the hand when exposed to its influence for a *prolonged* period, causing the skin to become shrivelled and pale, he dwells upon the following points:—

1st. That the water should be 98° or 100° Fahrenheit, or as warm as can be borne without pain.

2nd. It should fill the vagina and act on all parts of its surface, to effect which,

3rd. The syringing must be performed by a second person, a friend or nurse, whilst the patient lies on her back with her hips well raised.

4th. The injection must be continued 10 or 15 minutes, the water being thrown in very slowly.

5th. After the injection the patient must have absolute rest. Bed-time will be a favourable time for using it.

6th. The injections may be followed up by the use of astringent lotions once or twice a day, the following being a good one :—

℞ Potass. chlorat., ℥i.;
Acid. tannic., ℥ss.;
Aquæ, Oij. M.

A cupful, with a cupful of warm water, sufficient for each injection.

The patients frequently complain of weakness and weariness for the first few days after commencing this course of treatment, but this soon passes off.

The effect of the hot water is first to dilate, and subsequently to throw the vessels into a state of rigid contraction, blanching the parts.

The Inter-Universities Boat Race.

THIS great aquatic contest, which came off on Saturday last, was a very hollow affair, Cambridge winning by about seven lengths. Last year the race was won by Oxford by about the same distance. Thirty-three annual contests have now taken place, Cambridge being on the wrong side by one. The 1876 crews were a fine set of young men, decidedly above the average ; Oxford went to the post a little over-trained and less finished in style than their opponents. Neither crew appeared unduly fatigued at the end of their four and a-half miles row, showing the muscular powers and general *physique* of the men to be particulary good.

The Budget and the Profession.

ALTHOUGH the Government has determined to spend a much larger sum than usual upon the three branches of the public service, the Medical Department will be cut down to a starvation point, and probably left to die of inanition. The Chancellor of the Exchequer asks for forty millions of money to maintain the Army, Navy, and Civil Services in a state of efficiency, while the War Minister looks on with indifference, for he has not yet made up his mind to improve the quality of the raw material, nor pay the private soldier better ; and as for the grievances of medical officers, he cannot understand them. His conduct too, with regard to Netley, is incomprehensible, for he not only refuses to fill up the vacant professorship, but it is currently reported that he seriously thinks of breaking up the valuable school of military medicine in connection with the hospital. Mr. Hardy possibly hopes in this way to save a few hundreds, and lavish them upon the Knightsbridge barracks, which he has obstinately determined to rebuild upon a most unhealthy and inappropriate spot. However, not only is the school at Netley to be abolished, but the mess establishment, which nearly from the beginning of the present century has represented the head-quarters of the Medical Department of the Army, formerly at Chatham, is to be broken up, and its property dispersed. *Mirabile dictu*, all this is taking place under a Government we have been led to believe is "Conservative," but which is given to "jobbing" more than any Government of late years. Its estimates are perpetually going up, and yet the patent defects of the hour—the tenuity of the army, and grievances striking at the root of the Medical Department, the want of certainty as to the Fleet, the bitter discontent of the Civil Service—are in no way likely to be redressed or removed, and withal we are expected to pay an increased amount of income tax, and be thankful for the blessings vouchsafed to us by a Conservative Government.

Dr. Letheby's last Illness.

IN the memoir we last week published of Dr. Letheby it was stated that he had suffered from pneumonia, which appeared after his presence at the London Hospital, on the occasion of the Queen's recent visit. An additional note will interest many readers. From this attack of pneumonia, which involved the lower half of the left lung, Dr. Letheby was convalescent, when he was seized with acute peritonitis, which lasted just 44 hours. His friend Mr. John Jackson, F.R.C.S., who attended him throughout, thinks the peritonitis was probably due to perforation. But for this last attack, Dr. Letheby might still have been amongst us.

The Sewage Question.

PROFESSOR VON PETTENKOFER has been giving a course of lectures at Munich on drainage and sewage removal. The learned Professor is the President of the Imperial Sanitary Commission of Germany, and the foremost authority on hygiene in that empire, consequently his views are of great value.

A report of these lectures is being published in our contemporary the *Doctor*, which has the advantage of being revised by Prof. v. Pettenkofer himself, after translation and annotation by Dr. T. Whiteside Hime, of Sheffield, whose excellent translation of Pettenkofer's classic treatise "On Cholera" is probably fresh in the memory of many of our readers. Many valuable hints and statistics may be gleaned on the all-absorbing question of sewage from these lectures in our monthly contemporary.

The Vaccination Question.

AT Manchester, a public meeting has been held to express sympathy with Mr. Henry Pitman in his recent imprisonment for refusing to pay a fine imposed by the Altrincham magistrates for neglecting to have his child vaccinated. Mr. Pitman was four days in gaol, when his friends paid the fine, and he was liberated. Mr. Hugh Birley, M.P., though he disagreed with Mr. Pitman's conduct, sent a cheque for the amount.

A public meeting of one class or another may be at any time called together to sympathise with one who has had the sentence of the law passed upon him, whether justly or unjustly. It is therefore not surprising that Mr. Pitman's imprisonment should become a subject of discussion and expression of sympathy at a public meeting of those misguided people who have either never looked into the evidence of vaccination, or who have not the intelligence necessary to weigh that evidence. It is not, as a rule, among the educated and reading classes of the

people that the instances of neglecting vaccination are found, but among those who, being unable to form an opinion for themselves, act under the advice of others. It is not possible to appeal to the common sense or judgment of those people, or to explain to them by reasonable argument how the community at large may suffer greatly by their individual neglect.

The more forcible argument of punishment by fine and imprisonment, objectionable as it may appear in some respects, alone remains.

And it is to be regretted that a gentleman of position, who is aware of the mischief that may ensue from the violation of the law, should be found capable of illogically and foolishly assisting to mitigate its just penalties. The course taken by this Member of Parliament is especially objectionable, since the ignorant dupes of the anti-vaccination agitators are not aware that the letters M.P. attached to a name are not always a guarantee of the wisdom or discretion of he who appends them.

Anæsthetization during Sleep.

Dr. Cluness reports in the *Pacific Medical Journal* two cases of successful chloroformization during sleep.

The first case was that of a little girl, aged eight years, in whom, as a sequel to acute otitis media, the mastoid cells of one side became inflamed. Chloroform was administered upon a four-by-six piece of surgeon's lint, held as near the child's mouth as possible during sleep without coming in actual contact. Not the slightest effort was made by the child to avoid the inhalation of the anæsthetic, and in a few moments she was well under its influence.

The second case was on the person of a little girl two and a-half years old, for the purpose of having a supernumerary toe removed from each of its feet.

Russian Cure for Drunkenness.

The *American Journal of Pharmacy* says that for some time past *Herba serpylli* (wild thyme) has been used with great success to effect a permanent cure of drunkenness: in case of a relapse (only after years) a short treatment will effect a cure again. The treatment consists in making an infusion of wild thyme (1½ oz. to 1½ pints), and give the patient a teacupful every half-hour. The next day it is given every two hours, and then 4—6 times a day until the cure is complete, which generally takes from 2 to 3 weeks. The effects are in the following order: vomiting, diarrhœa, increased urine, strong transpiration, then generally increased appetite and craving for acidulous beverages. The diet: easily digested food and lemonade or other acidulous liquids.

A New Disinfectant.

Under the name of the "Universal Disinfecting Powder" has been introduced an extremely effective and soluble combination of chloride of sodium, calcium, and sulphate of zinc. Upon the addition of water chloride of zinc is formed in solution, one of the most powerful deodorants and antiseptics. Recent experiments upon the action of disinfectants prove that to be effective they must be lavishly used; and a combination which can be obtained for £10 a ton must be of great advantage to all public institutions; and in the army, where, owing to the large quantities of these substances required, economical considerations have to be taken largely into account. We can recommend this powder to the notice of the Control Department as a comparatively speaking non-poisonous anti-putrescent, extremely useful in infectious diseases, the poisonous germs of which can, in our experience, be best destroyed by a lavish use of the soluble chlorides.

Chloroform Again.

Another death from chloroform at Leicester follows this week close upon the heels of that in Liverpool which we reported in our last. Of course it is nobody's fault, the case being, as usual, that of a healthy subject submitted to an insignificant operation, and under the influence of a small quantity of the drug. The profession must by this time be well aware that there are in the community a certain number of persons whose peculiarity it is to be fatally sensitive to chloroform, and who will certainly die if submitted to its influence. They must also be aware that there is no means of recognising the idiosyncrasy except by the actual administration of the drug, and that the death is the first intimation of its existence, and that no precaution on the part of the administrator will suffice to avert the fatality. If surgeons conscientiously appreciate these indisputable facts, we really cannot understand how they can feel themselves justified in submitting patients to a danger which it is impossible to predestinate or to guard against. The pleas which we hear for retaining the use of chloroform may be truthfully interpreted to mean that the saving of an occasional life would be more than compensated by the discomforts of ether, and that after all the occasional victim must pay for the conveniences of the surgeon.

This is what the advocates of chloroform really say, though perhaps they hardly realise the significance of their words. We earnestly protest against such a line of argument, and maintain that a surgeon who continues to subject his patient to a danger of death for the sake of a mere matter of convenience—if there be any inconvenience in the use of ether—is seriously responsible. We are sorry to see the surgical profession going on from day to day in apparent indifference to the matter. Either the danger of chloroform and the harmlessness of ether are proved facts or they are not. If not, a competent scientific inquiry should be made, which would set at rest not only this question but the subject of the best means of administration.

We believe that almost all the alleged *désagréments* of ether arise from botchery in the method of its exhibition; but if these inconveniences were much worse than the warmest advocates of chloroform represent them to be, they would still supply no argument for preferring a dangerous to a safe agent.

Sanitary Condition of the Dublin Barracks.

A board of officers, under the presidency of Lieutenant-Colonel Vacher, Assistant Quarter-Master General, is now thoroughly overhauling the sanitary condition of the build-

ings occupied by the troops, with a view to the remedying of any defects which may be brought to notice. In so unhealthy a town as Dublin it is difficult to isolate completely the military from the many causes of disease which surround them; but owing to the great attention paid to everything connected with the prevention of disease in the army, the latter, as a rule, compares very favourably with the civil population amongst whom they are quartered. If the cause of disease is to be accurately ascertained, it is of the last importance that each case as it arises should be thoroughly traced and sifted in all its bearings, and the facts connected with it accurately recorded. When this is done the exciting cause is sure to be found, and the remedy becomes then a very simple matter.

Physical Education in the Army.

We are very glad to see that while the article on the above subject in our last week's issue was going through the press our well known contemporary the *Field* was at the same time drawing attention to the inferior *physique* of our troops, and was making suggestions similar to those we have already made. "When we consider," remarks that journal, "what would be the immense advantage to us of an army, however comparatively small, of trained athletes, we shall come to the conclusion that, as regards the athletic power of our soldiers we are as yet very far from perfection. What we want in a soldier is strength, stamina, endurance, agility, and speed." . . . . "Men need but very slight encouragement to the pursuit of athletics, and medical men will not be backward in testifying to the existence of good physiological and moral reasons for encouraging wholesome exercise and fatigue among such bodies of men as comstitute our regiments." We hope that we have already met this last suggestion, and that the "physiological and moral reasons" have likewise received from us due consideration. Whether, however, the hints which we and other journals have given on this subject will wake up the dormant energies of our military authorities is quite another matter. It is well known that they are very impatient of any outside interference, and that they are not very ready to adopt any other suggestions than those that have emanated from their own body.

Rheumatism as a Cause of Varicocele.

In a communication to the *Nashville Journal of Medicine and Surgery*, August 1875, quoted in the *Medical and Surgical Reporter*, Philadelphia, Dr. R. M. Corlen, of Cedar Hill, Tennessee, expresses his belief that varicocele is the direct result of rheumatism of the vessels themselves, in a large majority of cases. He instanced the case of a gentleman who first came under his notice suffering from a slight attack of lumbar rheumatism, which subsequently affected the sacral region and left hip-joint. Incipient varicocele was then detected, which gradually became worse. Under iodide of potash and other treatment specially directed against the rheumatism, the testes being suspended, he rapidly improved. After apparent restoration to health, for about a month, he again became the subject of intercostal muscular rheumatism, which changed by metastasis to the lumbar and sacral regions; the varicocele again made its appearance, yielding easily to the treatment proper to rheumatism. During several subsequent attacks the same sequence of events were noticed, the cord becoming swollen, tense, and tender. At other times it is soft, lax, and painless, and free from all inconvenience.

Mind in Plants!

We hope that our readers' breath will not be completely taken away at sight of the above extraordinary announcement. But such is really the title of a paper in a periodical called the "*Scientific American*," and a long extract of which has been inserted in a well-known London journal.

This wonderful piece of information is based upon the reputed speculations of certain scientific men. Thus, we are told "that Dr. Lauder Lindsay regards mind and all essential or concomitant phenomena as common in various senses to plants, the lower animals, and man." "Dr. Asa Gray attributes to plants a vitality and a power of making movements towards a determinate end, not differing in nature, perhaps, from those of the lower animals. . . Darwin has observed in the *drosera rotundifolia* a faculty for selecting its food, which in animals would certainly be attributed to volition." . . . "This plant," says another writer, "would bend towards a fly held within reach, enfold it, and suck its juices; but would disregard the bait if out of reach, showing not only purposive movement, but also a certain power of estimating distance"(!) "Again, Darwin has . . shown that the tendrils of various climbers frequently attached themselves to objects presented to them experimentally, but soon withdrew on finding the support unsuitable. He says of the *Bignonia capreolata* that its tendrils soon recoiled, with what I can only call disgust, from a glass tube or a zinc plate, and straightened themselves." Lastly, another writer says, in "carnivorous and climbing plants there is a choice or alternative between action and inaction, acceptance or refusal; and the choice made is not always judicious. There may be an error, and the error may be corrected; but in order to such correction there must be some kind of consciousness or perception that a mistake has been committed, an exercise of will in making further efforts at success, and a knowledge of means to an end, with their proper adaptation or application."

Such are a few of the quotations that have been made in support of the absurd notion that plants are actually endowed with what we call mind. We must admit that the unguarded expressions which are made use of by scientific men often justify the reader in crediting them with opinions they do not hold. But in the present instances we have something more than unguarded expressions, and the due interpretation of the language used not only shows what mistakes we are apt to fall into by not keeping in mind the proper meaning of common terms but how easily we may allow our imagination to get the better of our judgment. That plants constantly exhibit a remarkable irritability of tissue, a remarkable sensitiveness to external impressions, that some parts of plants have in an extraordinary degree the power of contracting, of expanding, and even of moving, in response to a stimulus acting from without, and that, in fact, the functions and attributes of the highest class of plants differ very little

from those ofthe lowest animals, very few will deny. But to magnify these automatic and wholly unconscious actions into mentalphenomena, and to dignify the most common operations of vegetable physiology with such a term as "mind" is so absurd, that our only excuse for troubling the reader with such wild speculations, is to amuse him with one of the curiosities of scientific (?) reasoning. That there can be no mind where there is no volition and no consciousness, and that there has never been shown to be, and never will be shown, either volition or consciousness in plants, are truisms which no sane individual would for a moment think of disputing.

The Army Medical School at Netley.

THE *British Medical Journal* believes that there is no truth in the statement which has appeared in some of the newspapers that Netley is to be abolished. It was not mentioned whether the Invalid Hospital or the Army Medical School at Netley was intended by the announcement. There is no ground for believing that the report emanated from any authoritative source.

Mortality in Ireland.

Health of the People.—The Registrar-General remarks that the increase in the mortality last quarter was chiefly amongst the aged. "Its causes are to be found in the many variations in the temperature during the three months and the heavy rains of the first six weeks. It is a gratifying fact that the deaths from those zymotic diseases which are to a great extent preventable, were less numerous than in any of the eight preceding quarters."

Although in some places the executive officers experience considerable difficulty in carrying out the provisions of the Public Health Act, the people generally are becoming sensible of the advantages of hygienic measures which have heretofore been sadly neglected, and their co-operation is easily secured: indeed in a few instances the Registrars' observations point to the fault resting with the local authorities and not with the inhabitants.

It should be mentioned here that several Registrars refer to the impossibility of any permanent sanitary improvements being effected among the humbler classes, so long as the poor are obliged to dwell in the wretched habitations which still disgrace many parts of the country.

Diseases.—The deaths from the principal zymotic diseases during the quarter formed 11·1 per cent. of the total deaths, and 48 in every 100,000 of the population. The average number of deaths from these diseases in the preceding eight quarters was 56·8; the deaths in the fourth quarter of 1874 reaching 62·6. *Small-pox:* Only 11 deaths from small-pox were registered, against 68 in the preceding quarter, 225 in the June quarter, and 239 in the March quarter. *Measles:* The number of deaths referred to this disease was 183, of which 84 occurred in Leinster, 25 in Munster (all in Cork Union), 63 in Ulster, and 11 in Connaught. The deaths from measles in the preceding quarter numbered 212. *Scarlet fever:* In the first quarter of the year as many as 1,107 deaths were caused by scarlet fever; the number fell to 913 in the second quarter, and to 788 in the third; but the returns for last quarter show an increase to 827, of which number 564, or 68 per cent., occurred in the province of Ulster. *Diphtheria:* This disease caused 134 deaths; the number is 39 over that for the preceding quarter. *Whooping-cough:* The deaths from whooping-cough were more numerous than in any other quarter of the year, and amounted to 401. *Fever:* The number of deaths from the various forms of fever was 538, being 60 under the number for the preceding quarter, and 96 under that for the fourth quarter of 1874. The deaths from fever were distributed as follows:—Leinster 161, Munster 158, Ulster 167, and Connaught 52. *Diarrhœa:* 447 deaths were ascribed to this disease. During the corresponding quarter of 1874, 426 deaths were referred to diarrhœa. *Simple cholera:* 8 deaths were tabulated under this head.

Inquests.—There were 692 inquests reported to the Registrars during the quarter, this number being equal to 1 in every 33 of the total deaths registered. In Leinster there was one inquest to every 28 deaths registered; in Munster 1 to 31; in Ulster 1 to 37; and in Connaught 1 to 45.

Prescribing by Chemists.

AT an inquest on the body of Henry Martin, an infant, aged seven months, at Limehouse, a few days ago, it was alleged that death was occasioned by the administration of an improper mixture prescribed and prepared by a woman, supposed to be the wife of a chemist. Dr, Harris, who was called in, said the deceased was dangerously ill, and ordered a warm bath. The same evening the infant went into convulsions and expired. Dr. Carpenter, who was also called in, said he had examined the mixture, which contained rhubarb, the administration of which in such a case as that under consideration would accelerate death. The inquiry was adjourned for the attendance of Dr. Harris.

DURING the recent examination for the Fellowship of the Royal College of Surgeons of England 29 passed. For the Membership 69 passed. Sixty-seven candidates were rejected for one or other of these diplomas.

PROFESSOR HUMPHRY has announced a course of lectures at the Cambridge University on the "Muscular System of Man and other Vertebrates," commencing on the 3rd proximo.

MESSRS. SIDNEY BERNAYS, Brudenell Carter, Carr Jackson, Reginald Maples, F. G. Marshall, and James Startin were elected members of the Pathological Society of London at the last meeting.

THE adjourned debate on "Syphilis" at the Pathological Society of London was concluded at a late hour on Tuesday last with an elaborate reply from Mr. Jonathan Hutchinson.

THE quarterly volume of the *Journal of Anatomy and Physiology*, edited by Professors Humphry, Turner, Foster, and Rutherford is just out, being as full of interesting matter as usual.

THE *British Medical Journal* announces that a civil list pension of £100 per annum has been conferred upon Dr. John Brown of Edinburgh, the author of "Rab and his Friends," "Horæ Subsecivæ," and other works, in recognition of his literary eminence. The announcement will be received everywhere with gratification.

A PENNY additional on the income-tax is one of the salient features in the new Budget. Incomes under £150 will in future be exempt, those from that amount up to £400 will be allowed an abatement of £120 instead of £80 as heretofore; the rest of the scale upwards is unaltered except by the unwelcome addition of a penny in the pound.

THE Will, dated November 28th, 1875, of Henry Hardinge, M.D., late of No. 18 Grafton Street, who died on January 28th last, was proved on the 15th ult., by William Money Hardinge, the son, Miss Jane Elizabeth Hardinge, the daughter, and William Henry Hatcher, the acting executors, the personal estate being sworn under £25,000. The testator gives the residue of his property, in equal moieties, to his said son and daughter.

THE Lectureship on Botany in the Ledwich School, Dublin, which was vacated by the death of Dr. D. T. Maunsell, was filled up last week by the proprietors of the school. Five candidates were named—Drs. Mitchell, Gogarty, Evans, Lapper, and M'Nab., but Mr. Evans and Mr. Lapper did not go to an election. Dr. M'Nab was chosen, and as he is Professor of Botany in the Royal College of Science, he brings to the duties a very special degree of competency. A Lectureship in Institutes of Medicine, now instituted for the first time in the same school, was conferred on Dr. Theodore Stack, who was the only candidate.

THE office of Resident Medical Superintendent of the Dundrum Central Criminal Asylum which was rendered vacant by the promotion of Dr. McCabe to be Poor-law Inspector *vice* Dr. Croker King appointed Commissioner, has been conferred on Dr. Isaac Ashe, Resident Physician to the Londonderry District Asylum. Dr. Ashe's appointment deserves all approval, for he has proved himself not only an excellent officer, but a man of culture and ability. He filled the residency of the Letterkenny Asylum before his promotion to Derry, and he was the author of the Carmichael Prize Essays given at two successive competitions by the Royal College of Surgeons for the best essay on Medical Education. The appointment which Dr. Ashe leaves is worth £340, and allowances of the further value of £160. That which he now acccepts is of the same value at first, but increases £10 a year up to £450.

Literature.

BENTLEY AND TRIMEN'S MEDICINAL PLANTS.

IT is with much pleasure that we welcome the first instalments of a work which has been long a great desideratum in medical literature. Of educational works on medicine and the collateral sciences there is and has been for years so abundant a supply that a student has some difficulty in making a choice between them, and the number and variety of text-books that are almost daily issuing from the press are such as to satisfy every kind of taste. But the want of a good and illustrated account of medicinal plants must have been felt by all who are either anxious to pass with credit our various examining boards, or who are actuated by the liberal desire to extend their studies beyond what is absolutely necessary to a practical knowledge of their profession. From Dioscorides down to our own times the study of medical botany has possessed a peculiar charm for some of our accomplished physicians, and from time to time—although at rather long intervals—the medical world has been presented with valuable contributions towards our knowledge of the natural history and uses of those plants that have been found by experience to possess medicinal virtues. Almost the last of those contributions was the well-known "Medical Botany" of Stevenson and Churchill. But this work has been long out of print, and a copy of it is now both scarce and expensive. There was therefore great need of a work like that which it is now our pleasing duty to notice. For although it may be objected that it is much better to study the plants themselves than mere illustrations and descriptions of them, it must be remembered that many of our most valuable plants are of exotic origin, and are seldom within the reach of the ordinary student. Indeed we have often wondered that a work of this kind has not appeared before, especially when we considered that every other department of medicine was well represented by many very excellent treatises and text-books.

We shall have another opportunity of noticing the work, but we may now mention that the coloured illustrations are remarkably good and true to nature, and that they represent all the plants that have been most recently introduced into our Materia Medica. The letterpress is, as we might expect, chiefly taken up with a full, accurate, and clear description of the botanical characters, habitat, officinal parts, production, and varieties of each plant, while just as much is said respecting its medicinal properties and uses as will complete the description, without trespassing too much upon the province of the therapeutist. A coloured plate is devoted to the illustration of each medicinal plant; and many of the drawings are taken from specimens furnished by the garden of the Apothecaries' Society, and by the Royal Gardens at Kew. Moreover, the quality of the paper, type, and general execution of the work leaves nothing to be desired, and we readily acknowledge that, when complete, it will form a very handsome addition to the library of every medical man.

ELEMENTS OF HUMAN PHYSIOLOGY. (a)

THERE is no department of knowledge connected with medicine which has made greater progress in recent years than physiology; consequently many and various are the physiological works which have been published. The majority of these engage themselves largely with histology and the minute anatomy of the different organs, and the means by which their function is performed. The necessity for all this in works of an elementary character is at once apparent, and in complete treatises, like Carpenter's well-known work, it would be undesirable to omit the histology. Hermann's book assumes the existence of this knowledge ere the commencement of its perusal. It contains no illustrations to aid the comprehension of the reader, and has only some diagrams on the most difficult parts of the consideration of vision. The plan of arrangement is that of four parts. Part I. is engaged with the exchanges of the matter of the organism, and occupies

(a) "Elements of Human Physiology." By D. L. Hermann, Professor of Physiology in the University of Zurich. Translated by Dr. Arthur Gamgee, F.R.S., Brackenbury Professor of Physiology in Owens College, Manchester. Smith, Elder, and Co. 1875. Pp. 587.

210 pages; Part II. comprises the activities or energies of the body, and engages 101 more pages; Part III. discusses the liberating apparatus, the nervous system taking up 210 pages; while Part IV. includes the origin, development, and death of the organism, completing the work. Hermann's manner of handling his subject is unlike that of other writers of physiological hand-books, and there is a great deal of information to be extracted from the perusal of this work not otherwise very readily reached. In the Introduction he writes: "The human body, like that of every other animal, is an organism in which, by the chemical changes of its constituent parts, *potential* is converted into *kinetic* energy." This is brought about by the oxidation of the constituents of the body, and the nervous system is the liberating apparatus by which such changes are produced. The different chemical changes undergone by our food are fully given, and the consideration of the ferments of the body is good. Then follows the blood and the circulation, including the innervation of the heart and blood-vessels. The manner in which the subject of secretion is handled will interest many readers. The chemistry of digestion and the mechanism of the digestive apparatus are equally satisfactory. The gaseous interchanges (income and expenditure) of the blood occupy Chap. IV., while Chap. V. takes up the exchanges of the matter of the blood, and in an Appendix considers the formation of glycogen and sugar in the tissues. In Chap. VI. we find the income of the body as a whole entertaining, as also its expenditure, and then the quantitative relationship betwixt the income, the expenditure, and the stock of the body are reviewed.

In Part II. we find the introduction of potential energy into the body, and the origin of the kinetic energy of the body, with an account of the expenditure of energy. "With the exception of the small quantity of energy which the organism loses in its imperfectly oxidised organic excreta (urea, uric acid, milk, &c.), all the potential energy of its food passes as kinetic energy to the outer world. This energy escapes from the body at rest only in the form of heat, whilst in the case of the body which is doing external work in the form of heat and mechanical work." Then follows a review of the influence of the conversion of energy on the exchanges of matter, where it is clearly put that the amount of nitrogenised waste is not the measure of muscular action. "We cannot, therefore, point out any act accompanied by the evolution of kinetic energy, for which the consumption of a particular kind of food (nitrogenous food) is absolutely necessary."

As to the development of heat within the organism, it is produced by oxidising processes which go on in the body, partly in the lungs by the union of oxygen with hæmoglobin, and elsewhere in the tissues of the body, except the horny tissues. When the body is at work a great deal of mechanical work is, by friction, converted into heat.

The movements of the body are next considered, and, firstly, the muscular movements. Very little is known of the chemical changes going on in muscles at rest. When a muscle is active the chemical changes are marked, and the venous blood is charged with effete products.

Then there are protoplasmic movements, as of contractile cells. The mass takes on a globular form, and where this is impossible approximates such form. After this, a consideration of the action of muscles generally, and then of their action in the production of voice and speech, follows.

In Part III. is given an account of the nervous system, called here the liberating apparatus, because it sets free energy into an active form. The nerves themselves are but poorly supplied with blood, and the chemical processes going on in them are but slight, either when at rest or in activity. A very different state of matters exists in the highly vascular brain, and its venous blood possesses the same characteristics as those of other tissues. As to the nature of nervous activity, most thinkers assume the existence in nerves of movable or alterable particles. There are centrifugally conducting nerve fibres, the motor, secreting, and trophic fibres; the centripetally conducting fibres of sensation; and intra-central fibres which unite central organs (ganglion cells).

The peripheral end-organs of nerves are considered at great length, such as the organs of sight, hearing, taste, smell, &c., and in a very interesting manner. After this comes an account of the central end-organs of nerves (central nervous organs). The following are the characters of central nervous organs:—1. The liberation of the active condition in a (centrifugal) nerve-fibre without the apparent participation of any external influence—*automatism*. 2. The liberation of the active condition in one (centrifugal) nerve-fibre brought about through another (centripetal) fibre—*reflex action*. 3. The phenomena collectively called *states of consciousness*, or *mental operations*, which are connected with the irritation of certain central organs. This division of the work will be most welcome to those who are interested in the recent investigations into the action of the nervous system. A good account is given of the different centres, as the respiratory and vaso-motor centres, &c., while the cortex of the cerebrum is described in its relation to states of consciousness, and to co-ordinated and associated movements. This chapter concludes with an account of the sympathetic nerve.

Part IV. is taken up with the life-history of the organism. As a whole, this work is to be highly commended. It is written in good English, free from idioms, and the translator must be congratulated on his discharge of a very difficult task. As to the matter of Hermann's Physiology, it is too well known to need comment. It is well printed, carefully corrected, and forms an attractive book.

Medical News.

Royal College of Surgeons of England.—The following gentlemen passed the Primary examination in Anatomy and Physiology, at meetings of the Board of Examiners, on Monday, Tuesday, and Wednesday last:—

Alfred Patron, Montpellier; H. L. Gilbert, St. Thomas's Hospital; W. D. Wilkie, Melbourne; V. G. Webb, Glasgow; C. B. Carter, St. George's Hospital; W. W. Edwards, St. Mary's Hospital; J. E. Gofton, W. J. Sweet, C. M. Goyder, and I. M. Young, Newcastle-on-Tyne; H. Leak, W. L. Child, A. E. Chambers, and C. R. Graham, Manchester; D. B. Fraser and M. M. Tucker, Toronto; H. J. Skelding, A. D. Blackader, and W. F. Scott, MacGill College, Toronto; A. Swann, J. H. Vinrace, G. J. Lloyd, S. A. Welch, and T. L. Hall, Birmingham; W. H. Owen, T. M. Porter, T. H. Bickerton, and C. E. Steele, Liverpool; G. Carter, E. C. Thompson, Perry Close, and J. D. T. Reckitt, Leeds; W. E. L. Batty, Liverpool; R. C. Birch, A. W. Cadman, F. Wilson, J. Deakin, W. F. Chadwick, J. T. Faulkner, and John Hodgson, Manchester; W. M. Ball, W. L. Batson, C. J. Bamber, G. H. Patterson; N. W. Bourns, A. W. Graham, C. J. Vlieland, C. B. Lockwood, and G. W. P. Dennys, St. Bartholomew's Hospital; G. B. W. Messum, J. F. Tabb, M. J. Hart, E. J. Morely, T. W. Fuller, R. Parry, and A. E. Mayland, Guy's Hospital; R. P. Smith, M. P. M. Collier, J. L. Hall, W. E. Woodman, H. J. Michael, G. A. Macdonald, and J. Shaw, St. Thomas's Hospital; G. H. Hetherington, H. Pearse, M. A. Smale, St. Mary's Hospital; F. B. Fisher, and G. A. Batchelor, London Hospital; A. A. Lendon, J. S. N. Boyd, and B. Pollard, University College; L. A. Hine, A. S. McCausland, E. A. Fardon, and J. McDougall Stewart, Middlesex Hospital; H. Elliott, Westminster Hospital; R. Margerison, F. N. Ozanne, E. Jennings, and W. A. Shann, St. George's Hospital; L. F. Cox, V. Matthews, and C. E. Baddeley, King's College; and J. M. Atkinson.

Sir Patrick Dun's Hospital, Dublin.—A bazaar in aid of

this institution was held in the Hall of the King and Queen's College of Physicians, Kildare Street, on last Wednesday and Thursday, March 29 and 30. The Hall was lent for the occasion by the President and Fellows of the College, and opinions are freely expressed that they acted injudiciously in giving their assent. A bazaar, with all its concomitants of bands, lottery tickets, baby-clothes, and pen-wipers, certainly seems rather out of place within the walls of an Esculapian temple, and under the protection of a solemn conclave of physicians. The abnormity may be explained by the intimacy of the connection which exists between Sir Patrick Dun's Hospital and the College, but nevertheless the association is a somewhat ludicrous one. We hear that the proposal was carried by the casting vote of the Chairman, which fact, if true, will serve as an apology for the Fellows.

Vital Statistics.—From the Registrar-General's return we learn that during last week 6,338 births and 4,205 deaths were registered in London, and twenty-two other large towns of the United Kingdom. The mortality from all causes was at the average rate of 27 deaths annually in every 1000 persons living. The annual death-rate was 23 per 1000 in Edinburgh, 24 in London, 29 in Glasgow, and 34 in Dublin. The annual rates of mortality during the same period in the other large towns were—Norwich 20, Hull 27, Leicester 18, Sunderland 21, Portsmouth 25, Newcastle-upon-Tyne 25, Birmingham 29, Brighton 21, Leeds 26, Wolverhampton 21, Bradford 29, Sheffield 23, Plymouth 27, Bristol 28, Oldham 43, Manchester 37, Salford 35, Nottingham 27, and Liverpool 34. The annual death-rate from the seven principal zymotic diseases averaged 3·7 per 1000 in these towns, and ranged from 1·1 in Newcastle-upon-Tyne, to 6·2 and 6·8 in Liverpool and Salford. Scarlet fever showed an increasing fatality in Bristol, and the high zymotic rate in Salford was due to the prevalence of small-pox, whooping-cough, diarrhœa, and scarlet fever. Eleven more deaths were referred to small-pox in Manchester and Salford, making 108 which have there been registered since the beginning of the year. Scarlet fever has been severely epidemic in Bristol during the last nine months, and has caused 559 deaths. Measles is fatally prevalent in Liverpool. Whooping-cough is fatally prevalent in London, causing last week 112 deaths or 37 above the average. The deaths from all other causes were under the average.

Medico-Parliamentary Intelligence.

MONDAY, APRIL 10.

CONGRESS OF HYGIENE.

The CHANCELLOR of the EXCHEQUER, in reply to Mr. R. Yorke, said the Government were not at all insensible to the advantages likely to result to the public from the International Exhibition and Congress of Hygiene to be held at Brussels, but having regard to all the circumstances of the case they did not feel themselves in a position to propose any vote on the subject.

MEDICAL RELIEF GRANTS.

The CHANCELLOR of the EXCHEQUER informed Mr. M'Laren that it was impossible to treat the question of medical relief grants for Poor-law purposes in Scotland by itself, but he hoped it would be dealt with in connection with the bill about to be introduced by the Lord Advocate.

RATING OF ST. THOMAS'S HOSPITAL.

Mr. SCLATER-BOOTH, in reply to Sir J. Scourfield, said his attention had been called to the recent case of the rating of St. Thomas's Hospital. The Valuation Bill contained the existing law, which based rating on gross rental or annual value, and not the capital expended in construction. He could not undertake to introduce a clause which would be contradictory of that principle for the exclusive benefit of any institution.

THE EAGLEY EPIDEMIC.

Mr. SCLATER-BOOTH, in reply to Mr. J. Cross, said it was not true that the Local Government Board had refused to hold an inquiry into the circumstances of this outbreak. On the contrary, he had resolved to despatch a government inspector immediately after Easter in order to carry out such an inquiry.

ELECTION OF PRESIDENT OF THE ROYAL COLLEGE OF PHYSICIANS.

ON Monday last the Fellows assembled in strong force for the purpose of electing one of their number to fill the chair which has been occupied so ably for the past few years by Sir George Burrows, Bart., and who from increasing professional engagements had declined the honour of re-election. The choice fell upon Dr. J. Risdon Bennett, M.D. Edin., F.R.C.P. Lond., F.R.S., the representative of the College on the Medical Council, Consulting Physician to St. Thomas's Hospital and to the City of London Hospital for Diseases of the Chest. The new President is a thoroughly representative man, and one whose opinions are entitled to respect.

THE RELATION OF SUBTERRANEAN WATER SUPPLIES TO ENTERIC FEVER.

ON Monday evening a paper was read before the members of the Social Science Association on the above subject. The cause of enteric fever, from which 8,000 or 9,000 lives were annually lost in England alone, the author said had now been shown by researches to be in all probability traceable to the presence of microscopic fungi which invaded the human subject, and which were developed in the dark and damp recesses of a porous soil, hence it was not surprising to find a correlation between certain water supplies and the spread of fever, especially when the water was obtained from wells or other subterranean sources. After dealing with numerous causes to which the epidemics of enteric fever were attributed, especially in the town of Croydon, he traced it in every instance to the condition of the water, the distribution of fever being the more severe when there was a large flow of surface water into the springs.

NOTICES TO CORRESPONDENTS.

☞ CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

READING CASES.—Cloth board cases, gilt-lettered, containing 26 strings for holding each volume of the MEDICAL PRESS AND CIRCULAR, can now be had at either office of this Journal, price 2s. 6d. The postal regulations not allowing the Journal to be stitched, these cases will be found very useful to keep each weekly number intact, clean, and flat, after it has passed through the post.

WE are requested by Dr. Davys (Swords) to add his name as subscriber to the amount of £5 5s. to the fund for the Poor Medical Student referred to in one of our recent issues of THE MEDICAL PRESS AND CIRCULAR.

JOTTINGS IN INDIA.

"FROM the letter of a well-informed correspondent in India we extract the following remarks, some of which will be seen to bear upon many points to which editorial reference has frequently been made in our columns. Speaking of the station at which he is quartered as medical officer in charge, he says: "The daily medical work here is very interesting, but very little of it crops up in print. Far more serious and complicated cases than people in England have to deal with—hepatitis, dysentery, hepatic abscess, intermittent, remittent, enteric, puerperal fevers, we have ample experience of. If I live to put in two years more and to return to work at home stations, there are many wrinkles learnt which will be of value. Our hospitals here are far cleaner, neater, and more wholesome than many vaunted establishments in London, Dublin, or Edinburgh. What we want in India are good libraries in all large stations. Books are very heavy to carry, and sell for nothing. I take in the *Lancet*, MEDICAL PRESS, *Medical Times*, and *British Medical Journal*, and it is so annoying to find sometimes the same author's paper in all the journals. A curious thing, too, is that a certain number of London writers monopolise so much prominent space week after week. Where are the medical men in country practice? What becomes of their invaluable experience? To-day, turning over a heap of medical literature, I could extract but very little about the varied phases of every-day cases—say of children's diseases. The prefaces of books also strike me as very amusing—'all are prepared to supply a want—to facilitate the daily work of the busy practitioner.' What becomes of the practitioner who is not busy? Where are the books for him? Pitiable is it to read of *the struggles for bread, the alliances with chemists, small fees, squabbles about a few shillings, and the paid contradictory opinions in courts of law.* It is the publication of these things that prevents the medical profession from rising. Yet a lawyer who defends sneaking thieves and murderers may become a Peer."

IRISH POOR-LAW INTELLIGENCE.

VACCINATION PROSECUTIONS.

An important question, which has been frequently in dispute both by the Local Government Board and by Boards of Guardians, has been decided by a competent legal tribunal at the instance of the Council of the Irish Medical Association. It may be recollected that about three years ago the question of the liability of medical officers to attend and give evidence in vaccination prosecutions was first raised in the Abbeyleix Union, and the Local Government Board then decreed that the medical officer must attend whether paid or not. To this verdict the Medical Press and Circular emphatically demurred, and pointed out the fact that the dispensary regulations which set forth the duties of the medical officer contained no such proviso. Thereupon the Local Government Board withdrew their former letter, but they have continued to insist on the attendance of the medical officer as a witness, and have discouraged any attempt of his to obtain payment for such services. In the early part of this year the matter was revived on the occasion of an application by Dr Kisby, of Boyle, to his Board of Guardians for payment of his fee for giving evidence against vaccination defaulters. The application, apparently at the instance of the Clerk of the Union, was refused, although Dr. Kisby produced the magistrate's order (which is necessary under the 13th section of the Vaccination Amendment Act), and laid before the Guardians cases in point, and also the official declaration of the Local Government Board that a medical officer was entitled to payment under the circumstances, the ground for refusal being that, though the Act orders payment of "expenses," no expenses were incurred by Dr. Kisby, inasmuch as he had not to travel far to the court. Dr. Kisby, on this refusal, appealed to the Local Government Board, who refused to make any order for his payment and he then applied to the Council of the Irish Medical Association for its advice. The Council, seeing the importance of establishing the claim with due legal authority, for the benefit of the dispensary medical officers of Ireland, undertook the responsibility and expense of enforcing payment by law if necessary. They, however, in the first instance addressed courteous requests for payment to the Guardians, who took no notice of them, or of the application of the Council's solicitor, but took defence to the process, which was heard by Mr. Hamill, Q.C., on the 31st of March. In opening the case, Mr. Burke, the solicitor for the Association, pointed out the duties of the medical officer under the Act, and the liability cast upon the guardians to prosecute parties who did not comply with its requirements, and that when the guardians proceeded by summons to enforce penalties, they required the attendance of the medical officer as a witness in court to enable them to sustain their case, and that the doctor, being duly registered, was clearly entitled to be paid for his evidence and attendance under the 21st and 22nd Vict. cap. 90, secs. 31 and 32.

Mr. McDowell, the Solicitor for the Guardians, resisted the claim, and contended that it was the duty of the doctor to attend the Petty Sessions Court and give evidence, and relied upon the fact that he was sanitary officer under the Public Health Act, and therefore bound to attend when required to carry out its provisions. The Chairman, Mr. Hamill, Q.C., in giving judgment, said he considered it no part of the medical officer's duty to attend as a witness in a court to assist in carrying out a Compulsory Act on a summons or order of the guardians to attend the court. An important duty was cast upon the guardians, to enforce compliance with the Act for the benefit of the public, and it was idle to say that they should issue summonses against defaulters and have no witnesses to sustain their prosecutions. They are bound to sustain their cases, and how could they do this without the doctor's evidence? The guardians had not, in this case, actvally summoned the doctor, but they sent their agent, the relieving officer, to direct him to attend. He complied with their request, and they were clearly bound to pay him. He would therefore give a decree for one guinea for his attendance, with costs.

The Solicitor for the Guardians spoke of an appeal from this decision, but the Chairman suggested that the Guardians had better not incur such a useless expense. While we congratulate the dispensary medical officer on t fact that the Council of the Irish Medical Association and Dr. Kisby have finally established their right to fees in these cases, we anticipated the decision, and we trust that every public vaccinator will make it a rule to apply to the magistrate for the necessary certificate, and insist upon payment for their own and their profession's benefit. We strongly advise the dispensary medical officers of Ireland to make no difficulty about attending the court and giving their evidence, but to get a requisition from the relieving officer if possible in writing. If the magistrates should refuse to make an order under the 31st section of the

Vaccination Amendment Act, it will still be necessary for the Guardians to pay the fee as a matter of si mple contract.

We cannot but regard with regret and disapproval the course adopted by the Local Government Board in endeavouring to impose this function upon their officers contrary to the law, and in refusing to lend them any assistance in their effort to obtain payment. As long as his demand is legal, the medical officer has a right to expect the support of the department under which he serves, and the Local Government Board will never gain anything by unreasonable dealing with their subordinates. Medical officers should be made to do their duty, but, when done conscientiously, they should be fairly paid what is due to them. We expect nothing but stinginess and trickery in such matters from boards of guardians, but we ought to hope for a higher principle in the Local Government Board.

Hasty.—One of the oldest and ablest practitioners of Butler County, Pa., relates the following (Trans. Pennsylvania State Medical Society, 1875):—M. G. is a worthy farmer of the Celtic race. He came into the doctor's office with his arm hanging down, and a look of pain on his face. The doctor was going out, but stopped with a "What is the matter, M.?" "Shure, sur, I fell on the barn flure and hurt me arm." "You did, eh; well, off with that coat and shirt." Off came the articles, and after a moment's examination the doctor exclaimed, "Why, man, your shoulder is out!" "Well, doctor, can you fix it?" "Oh, yes; lie down on that lounge." Before he complied he said a few prayers and took a drink of whisky. Without more ado he was put through all the manipulations known to ancient or modern surgery, with no good result. The patient became exhausted, cross, and discouraged. The doctor, perplexed, his shirt soaked with perspiration, sat glowering at Mike in despair, when a thought struck him, and he asked, "Mike, when did you do this—get this shoulder out I mean?" "Shure, sur, I think it was *about twenty-two years ago, in Ireland.*" Two men put on their coats in short order, and one never attempts to reduce a dislocation without asking "*when?*"

GENERAL SUMMARY OF DISPENSARY STATISTICS.

YEAR ENDING SEPTEMBER, 1874.

Heads of Particulars.	Ulster.	Munster.	Leinster.	Connaught	Total for Ireland.	Averages. Unions.	Dispensary Districts.	Medical Officers.

ON THE SCIENTIFIC AND EMPIRICAL INVESTIGATION OF EPILEPSIES.

By J. Hughlings Jackson, M.D., F.R.C.P.,

Physician to the Hospital for the Epileptic and Paralysed, and to the London Hospital.

CHAPTER VII. (*continued from p.* 176.)

The first thing we do in the scientific investigation of a case of epilepsy is, as in a case of palsy, to localise the lesion—to seek the organ damaged. In no case of nervous disease of any kind is there any *rational* clue to the seat of the internal lesion other than that furnished by observing the external symptoms. The principle, which seems, and indeed I think is, a mere truism, is not fully acted on in practice. It is carried to its logical conclusion in cases of paralysis of muscles, but not in cases of mobile affection of muscles, chorea, convulsion, &c. Most careful attempts are made to describe the regions affected in palsies. But there is little, if any, attempt made to note the regions affected in cases of chorea and convulsion. We are told that disease of the surface of the brain "causes epilepsy," but we are often not told what regions of the body are first in spasm in the paroxysm, or that one side is convulsed, or convulsed first and most. No one could imagine that there was any other way of finding out the seat of the internal lesion in a case of paralysis than by studying carefully the external region paralysed. If the face, arm, and leg are paralysed on the left side, the arm suffering much more than the leg, we can infer that the lesion is in the right corpus striatum. If the face is paralysed on the right side, and the arm and leg on the left, we declare the lesion to be on the right side of the pons Varolii. And if we were asked to declare the seat of a lesion when told simply that the patient "was paralysed," we should think the question a strange one, and reply that we could not tell. But no such minute work is attempted in cases of convulsion. It does not appear to most people at all a strange thing to be asked, "Where is the seat of epilepsy?" For "epilepsy" is to them an entity, and it appears a fair question to ask where is the seat of the change causing it. It is often taken as proved that the seat of the discharging lesion in general convulsion is the medulla oblongata. But this assumption, granting for the moment its correctness, is no justification for the neglect of a minute study of the paroxysm. Those who hold "orthodox" opinions on epilepsy admit that the paroxysms differ in different patients. If so, different parts of the medulla oblongata must be discharged. Here I give authority for the double statement that fits differ in different patients, and yet that the fits in the same patient are very much alike.

Voisin (*a*) writes:—"Axenfield a fait remarquer que les attaques se reproduisent le plus souvent avec une uniformité absolue, avec leurs auras, leurs caractères propres et leurs complications. Il s'établit une sorte d'habitude d'après laquelle tel individu sentira toujours la même aura, poussera toujours un cri et le même cri, tombera sur le même point du corps, le front l'occiput se blessera de la même façon, présentera les mêmes mouvements convulsifs, se mordra le langue au même point, se luxera toujours une même épaule, sera toujours pris de délire après l'attaque."

This being so, those who hold that the medulla oblongata is the part of the nervous system which discharges in the epileptic fit have, as much as others, to note *paroxysms* with great care, in order to find out how it is that in one patient there are fits of a certain kind, and in another of another kind. If, then, epilepsy *is* a disease of the medulla oblongata, differing fits in two patients must depend on discharge of different parts of the medulla oblongata, however much the seizures in the two patients may agree in the most fundamental characteristics required by the ordinary definition of epilepsy.

The following quotation from Falret, *Etat Mal des Epileptiques*, is given to show that epileptic paroxysms differ, and yet that in the same patient they are uniform.

(*a*) "Nouveau Dictionnaire de Médecine et de Chirurgie Pratiques," p. 959, Art. Epilepsie. This is an article of great value.

I draw particular attention to the parts italicised. It is true that the quotation refers chiefly to the mode of onset, but this is the most important matter in localisation. The part first convulsed, for example, is the part which has the leading representation in the centre discharged. Falret is speaking, too, of mental symptoms, but the principle is the same. A fit which always begins by the same "remembrance" is evidence of a *local* discharge as much as is a fit which always begins by colour vision. I do not think, however, that these intellectual auræ are symptoms of the same kind as coloured vision, or local spasm, as I shall try to show at length later on.

Falret remarks first, however, that the convulsive attacks of epilepsy must often occur suddenly without being announced by any symptom "soit physique soit moral." This is what one would expect of cases of epilepsy in asylums; for a fit to begin without a warning is for the fit to begin with loss of consciousness, that is, for the discharge to be of the very highest nervous arrangements. Theoretically, we should expect that the epileptic patients who are most likely to become insane would be those who have discharging lesions in the very highest nervous arrangements.

Crichton Browne (West Riding Asylum Reports, vol. 3, p. 160) says: "In lunatic asylum practice an aura is of rare occurrence in epilepsy." This may, however, be, as he points out, in part because epileptic lunatics are epileptics far advanced in their disease, and thus are unable to describe their symptoms exactly. The following is the quotations from Falret:—

"Independently of these precursory symptoms, which may occur at a distance greater or less from the epileptic attack, there are other more immediate intellectual premonitory symptoms, a kind of intellectual aura, which precede the convulsive attack only by some minutes, and which constitute in some kind the first symptom of it. One sees, for example, some epileptics in whom the same idea, the same remembrance, or the same hallucination occurs spontaneously at the moment of commencement, and infallibly precedes its appearance. The patient sees flames, circles of fire, frequently the colour red or purple, a spectre, or a phantom; he hears the noises of clocks or a determined voice which pronounces always one word; sometimes he has finally a certain smell. *These ideas, these remembrances, these false sensations, which differ singularly in different patients, are generally reproduced with remarkable uniformity in the same patient at each new attack.*"(a)

It is true that the study of the region affected in cases of palsy is easy; we can do it quietly, whereas in the simplest epilepsies, those with convulsion, the motor affection is so sudden and so quickly over, that we may be tempted to deal in generalities, and especially to give a pictorial rather than a scientific description. But the work must be done. If we could safely omit it clinically, we could not physiologically. We must describe the paroxysms not only on a method analogous to that in which a gardener would describe a plant, but also in the deeper way in which a botanist would describe a plant; we must observe analytically, *i.e.*, the relations of the several phenomena to one another, both in co-existence and in succession. To observe an epileptic paroxysm with a gardener-like mind would be to dwell most on the struggling, the foaming, the staring eyes, and the tongue biting; to describe it with a botanist-like mind would be to note where the first symptom showed itself, how the spasm spread, when consciousness was lost, &c. Both kinds of observation are essential, one for empirical, and one for scientific diagnosis.

In localising we shall not specially concern ourselves with the *condition* of the muscles in the range affected by convulsion. The *condition* of muscles tells us plainly what the functional nature of a lesion is—whether it be a destroying lesion or a discharging lesion. It is the regional affection which localises. It matters little for purposes of localisation *how* the muscles in any region are affected. Thus paralysis of the face, arm, and leg (hemiplegia), irregular movements of the face, arm, and leg (hemi-chorea), occasional spasm of the face, arm, and leg (hemi-spasm), all point to lesions of the same cerebral region, although to different kinds of lesions of that cerebral region. We say that hemiplegia and hemi-spasm both depend on lesion of the same cerebral region, because the muscles affected are the same. We say, too, that the functional nature of the lesion in each is different, because in the hemiplegia, since the muscles are palsied, nerve tissue is destroyed, whilst in the hemi-spasm, since the muscles are in occasional spasm, that nerve tissue cannot be destroyed, but is unstable, and discharges occasionally. (a)

Very likely it will be denied that there can be a local lesion in many cases of epilepsy—for example, in those cases of convulsion with loss of consciousness, which are called genuine epilepsy by authorities. In these cases there is often a universal affection—convulsion all over the body. It seems at first glance unlikely that this should depend on a local discharging lesion in but one side of the brain. However, I believe it does; I believe there is limited instability of some part of but one cerebral hemisphere in these cases. The evidence will be given when speaking of convulsion beginning locally and becoming universal. Again, there is often loss of consciousness at the onset, and it seems at first glance unlikely that a *local* discharge in but one of two cerebral hemispheres should cause this symptom—cause it as the very first thing, I mean. This will have to be considered later; we have already replied indirectly to the objection in speaking of the different seats of varying consciousness. That pallor of the face should occur in these cases seems to me explicable by the fact, if I may call it one, that the vaso-motor system is represented in the cerebrum; thus the arterial muscular coat suffers, as do the large muscles. For the present we shall take into consideration the simplest cases, those in which the external symptoms are partial, that is, cases in which some part only of the body is affected.

Of these cases we may say that the very fact that the movements are local (one sided) shows there to be an internal local lesion. Local symptoms must of necessity depend on local lesions. If it were not so, all that has been written by all observers on localisation would be sheer nonsense. It is no answer to this remark to point out that a local symptom has been very transitory, or to say that there is only "functional" change in any sense of the word functional. The point of first importance in localisation is not the degree of the symptom, but obviously its localness. And as to slightness of charge, if we were to hold some such vague hypothesis as that epilepsy or convulsion depends on a "polarisation of the molecules of nervous matter," then in a case of hemi-spasm there is *local* polarisation in nerve-cells so long as the symptom continues to be presented. Or if we were to return to the oldest hypothesis—that there is Satanic possession—then in local seizures the possession must be of some part of the nervous system.

What is said of motor discharge applies also to sensory discharges. A fit which *begins* with coloured vision must

(a) Fabret continues:—"It is curious to add that very often this remembrance, this idea, this image is the reproduction of the idea or sensation which provoked in the patient the first epileptic attack. Many among them in fact, become epileptic after some strong moral emotion or profound terror, and see in their mind or under their eyes at each fresh attack the painful circumstances or the frightful scene which produced the disease in them the first time." These facts will be referred to later on.

(a) I do not say that the *condition* of the muscles is of no value in localising. In a certain sense it is of very great value, as I shall point out later on. The region affected, however, is the most decisive evidence as to the seat of the lesion. I shall try to show that in discharges of the highest centres there is greater intensity of current from their discharge (greater quantity of nerve force in a given time), whilst in subordinate centres there is greater quantity of force from their discharge, and that this difference accords with the morphological difference, the sizes of the nerve cells. Thus from the kind of spasm we shall learn something as to the seat of the discharge.

depend on a discharge of a different part from one which begins by a sensation of smell or of sound, however much the seizures may resemble one another in their progress after the warning.

We cannot now localise in many cases, but there is one thing we can do now—we can observe external symptoms in *an orderly manner*. It is just what we do in cases of palsy. We describe minutely the range of the palsy and minutely the degree in which the several paralysed parts suffer.

Of course the investigation does not end in the study of the parts affected in the paroxysm. We have already spoken at length on the pathology of such cases. We must, however, study the external symptoms carefully. It is not of much value now-a-days to say that a tumour of the brain in the region of the middle cerebral artery produced convulsion (or epilepsy or an epileptiform seizure) unless we know what kind of convulsion it was, any more than it is of much value now-a-days to say that a tumour of the corpus striatum produced paralysis unless we know what sort of paralysis there was.

It is believed, as aforesaid, that the discharging lesion of every epilepsy is a local one, and that on the beginning of the discharge depends the first symptoms of the paroxysm. Some of the further symptoms probably depend on discharge of healthy nerve-tissue; the unstable part gives rise to strong currents, which not only pass direct to muscles, but to lower healthy centres, and also probably by the intermediation of arterial contraction to neighbouring healthy centres and discharge them.

There seems to be great inconsistency in the commonly received or commonly acted upon principles of localisation. No one would think of denying permanent and complete hemiplegia to be the result of a local lesion, but when the case is a mobile affection of the very same muscles it is denied in effect, or rather it is ignored. The reason probably is that in the intervals of his fits the patient is apparently quite well. As has been several times stated, the principles of compensation and of dissolution fully explain the seeming discrepancy. If the patient's fits are local, frequently recur, and are always similarly localised, it is surely a necessary inference that there is some local disease in his nervous system.

It is equally obvious that if in two cases two different external parts are affected that in each there is a differently placed internal local lesion. It is no answer to this to bring evidence to show that most careful investigations have discovered no lesions post-mortem in such cases. This is very true indeed, but it is no objection to the method as method. Suppose a patient has occasionally a sudden stench in his nose, followed by loss of consciousness for a short time, we may not be able to declare where the lesion is. But it is still certain that there is a local lesion in some part of the nervous system, because a certain part of the body is affected (sensation locally referred). It is just as certain after a careful post-mortem examination which discloses no traces of local lesion. What is uncertain is the particular locality. To deny that partial external symptoms imply internal local lesions is to deny that there is any kind of organisation in the nervous system. If local external symptoms do not imply corresponding local internal lesions, it is, I repeat, sheer nonsense to attempt studying the localisation of nervous disease at all.

The minute study of epileptic or epileptiform convulsions has met very little favour. We have, it is true, many descriptions of the "epileptic" paroxysm, but we have very few reports which give an exact description both of the muscles most convulsed, and of the order in which they are convulsed. And I know of few attempts to give an account of the whole of the phenomena which occur in the *simplest* cases of convulsions. The object seems often to be, from a very general view of the phenomena—such as the universality of convulsion, tongue biting, loss of consciousness, &c.—to be able to say only whether the paroxysm be an epileptic one or not—whether it be epileptic or epileptiform. Thus we hear the diagnosis of cerebral hæmorrhage negatived because the patient had a fit of an "epileptic character." Yet the convulsion from cerebral hæmorrhage may be just like convulsion from many other causes, or it may be safer to say it has not been shown to be different. In all severe convulsions the patient may bite his tongue. (*a*)

Of course convulsions from a clot in one side of the brain, due to sudden breaking up of grey matter, or to irritation by the suddenly intruding foreign body, are utterly different, *pathologically*, from chronic cases of epilepsy; but they have their counterparts anatomically.

I have no doubt that to some these remarks will be mere truisms. But I know well that by others the principle will be denied, and by many it is ignored. It seems to me to be denied in effect by those who attribute local seizures to very general conditions as their sole causes. This is not at all uncommon. For example, cases of convulsion beginning in one hand, affecting the face, arm, and leg, of but one side, are attributed to fright, and we even hear of emotional hemiplegia. Almost always there is only evidence of sequence. No one of course denies that fright produces certain severe nervous symptoms; but where is the evidence that it produces any local nervous symptom? and where is the evidence that it is in cases of epilepsy more than an exciting cause of the discharge of some part of the nervous system already unstable. The principle is ignored by those who do not attempt to study regional spasm in as realistic a way as they do regional palsy. But these may ignore it for the intelligible reason that it is not practicable, or that, if practicable, it is a kind of work not worth doing.

It must be particulariy borne in mind that there are all degrees of seizures, or, as we may say, all degrees of discharge. When the discharge is slight and limited we have a development only of the most special movements and impressions represented in the part unstable. Thus there may be spasm of the index finger only, red vision only, subjective sensation of smell only, or a feeling at the epigastrium which is, I think, a crude development of certain systemic sensations. For these the word "aura" is often used as synonymous with warning, and sometimes there is the warning only — the fit is abortive. These are developments of what is *most* represented in the part discharged. Similarly there may be loss of consciousness. This, and even only defect of consciousness (confusion of thought), stands in the same category as the earliest symptom developed. (*b*) What I wish now to assert is that a so-called aura is not a fit of a different kind from one which goes on to universal convulsion. It is an aborted paroxysm. Loss of consciousness, however, is not commonly called a warning, nor of course could it be one to the patient. It is not here a word and a blow, but a blow first, and only. Instead, then, of aura or warning, we shall use the expression first symptom, including in that both what the patient can tell us and what we see. Spasm of the index finger, subjective sensation of smell, loss of consciousness, are all

(*a*) Under Diagnosis Jaccoud says, in his article on Epilepsy:—"A ne considérer que l'attaque elle-même, l'épilepsie ne diffère pas de l'ECLAMPSIE; mais cette dernière, qui est un *symptôme*, et non pas une *maladie*, est caracterisée par la répétition des accès coup sur coup, par la rapidité de la terminaison, mortelle ou favorable, et par les conditions étiologiques spéciales qui lui donnent naissance (puerpéralité, urémie, intoxication saturnine; chez les enfants, dentition, irritation intestinale). LES TUMEURS CEREBRALES, et plus généralement les lesions de l'encéphale, provoquent souvent, par l'action directe ou à distance qu'elles exercent sur la bulbe, des convulsions dites *épileptiformes;* la similitude de ces accès et de ceux de l'épilepsie légitime peut etre absolument complète, c'est donc dans la situation de malade pendant l'intervalle des attaques que doivent être cherchés les caractères différentiels."

(*b*) Of course, strictly, the comparison is not that affection of consciousness in discharge of the highest nervous arrangements is analogous to spasm of the hand from discharge of a subordinate series; the comparison is betwixt the earliest movements (for we can here learn nothing about sensation) developed in those excessive discharges of the highest nerve centres during which consciousness ceases and the spasm of the hand.

due to the beginning of a discharge leading to development in a brutal form of the impressions and movements most represented in the unstable discharging part.

A paroxysm of spasm of the hand (tonic followed by clonic) is not then a *different* kind of fit from one which, beginning also in the hand, spreads all over the body. It is a fit of slighter degree. The proof is that patients who have partial fits often have also fits which, beginning like the partial ones do, become universal. Again, there are all degrees from epileptic vertigo through *petit mal* to *grand mal;* but they are not different kinds of fits. They are, however, not differences of simple degree, but of compound degree.

Another thing to be carefully noted in paroxysms of convulsons is the March of the Spasm. A patient may have convulsion varying in degree from that slight degree in which the index finger and thumb only are convulsed to universal convulsion. We have to note how it *becomes* universal. Let us take an arbitrary limit for illustration. We will suppose we witness a paroxysm in which the convulsion affects the whole of one side of the body, that of course in which the spasm begins. It most often begins in the hand ; and we will suppose we witness such a case. We have to note how one part of the arm after another is affected ; at what stage the face is affected ; how the spasm spreads over it ; if the spasm goes up or down the leg, and so on. We should then be able to say not only that the part discharged represented the index finger and thumb, but that it (and other centres of grey matter directly controlled by it) represented certain other movements in subordination to the movements of these digits and in a particular order of subordination.

BILIARY COLIC. (*a*)

By Thomas Hayden, F.K. & Q.C.P.I.,
Physician to the Mater Misericordiæ Hospital, &c.

The details of seven cases were given, in which the paroxyms of colic were very severe, and repeated, and in some, of the most aggravated character. The symptoms were pain at the epigastrium and right hypochondrium, extending over the abdomen to the back, with fixed pain at the right scapula, great prostration, amounting in one case to syncope, vomiting, slight jaundice, with bile, pigment in the urine, and constipation. From five of the patients gall-stones were obtained, and in one instance large quantities of the seeds and core of fruit.

The calculi were of the most varied character as to size and figure, but composed mainly of cholesterine and inspissated bile ; 45 were obtained from one patient, and 10, not larger than duck-shot, granulated on the surface, and evidently examples of hepatic calculi, from another.

Death occurred in two of these cases, preceded by symptoms of pyæmia, and in one of them a biliary fistula had been long previously formed.

The other five patients recovered perfectly, and one of them has been for more than 16 years free from recurrence of his symptoms.

An attack of biliary colic is usually preceded, for several months, by flatulence, acid eructations, and a sensation of fulness and discomfort in the region of the liver some hours after meals. The bowels are constipated, and the urine exhibits from time to time a copious deposit of urates. Anomalous pains of a remittent character, referred to the back and nucha, are likewise frequently complained of. The earliest intimation of an actual seizure consists in a thrilling sensation at the epigastrium. This is soon followed by colicky pain radiating through the hypochondria, and extending to the inferior angle of the right scapula, where it is felt with especial severity. The abdominal muscles become rigid, the stomach inflated, and gaseous eructations and vomiting occur without relief to the patient's sufferings. The pain is remittent and paroxysmal, and of the most excruciating character ; it usually lasts several hours, but may may continue for a much longer period, and then ceases quite abruptly. The pulse, during a severe paroxysm, is slow and very feeble ; the surface cold, and bathed in perspiration. Within twenty-four hours after the attack there is usually jaundice and the urine is coloured with bile, whilst the fæces exhibit a want of it.

The recurrence of these attacks is uncertain as to time, but liable to be determined by indiscretion in diet, and by violent succussion of the body. The earliest are supposed, on theoretical grounds, to be the most severe ; but I think those which occur at a somewhat later period, the third or the fourth, are usually attended with still greater suffering and prostration.

Jaundice is not unfrequently absent after the earlier paroxysms. But even in such case the diagnosis cannot be difficult if due weight be given to the special symptoms, thrilling at the epigastrium followed by pain of a spasmodic character, extending to the right scapula, accompanied by sudden inflation of the stomach and vomiting, and abruptly ceasing after some hours ; hepatic dulness being somewhat extended, with corresponding tenderness to pressure.

The smooth, round, and yielding tumour mentioned by authors, as formed by the distended gall-bladder, cannot be felt during a paroxysm owing to the tension of the abdominal muscles ; and even during the intermissions, except in cases of extraordinary distension, the evidence furnished by this symptom is eminently inconclusive.

In cardialgia there are other symptoms sufficiently distinctive of gastric dyspepsia ; the pain due to this cause commences soon after food has been taken, whilst that of hepatic colic not for some hours.

During a paroxysm, the bowels should be unloaded by a turpentine enema, and the patient should be placed in a warm bath of 105 deg. F. If relief be not thus obtained, an event which I have never witnessed, or if the bath cannot be readily provided, a hypodermic injection of a quarter of a grain of morphia should be given. In the intervals, a few grains of blue pill with extract of belladenna and dried soda should be given thrice daily, and occasionally a rhubarb or seidlitz draught. Chloroform may likewise be administered by inhalation, but short of anæsthesia, during the attack ; it is, however, less efficacious than morphia given as proposed, and the relief which it affords is of shorter duration.

I have not tried sulphuric ether and spirits of turpentine, as recommended by Durande, nor do I think the stomach would be likely to tolerate it ; neither have I, for the same reason, given chloroform by the mouth, as suggested by Bouchu, or Prout's favourite remedy, large doses of a dilute solution of bicarbonate of soda. The general treatment, with a view to cure, should have reference chiefly to diet and exercise. Fats, sugar, hot bread, malt drinks, highly-spiced dishes, and rich soups, should be avoided. Claret and the alkaline effervescing drinks, soda and and seltzer water, should be freely used. Green vegetables, especially spinach and broccoli, likewise fresh ripe fruit, and plain pudding without fruit, may be used. Food should be taken in moderate quantity and frequently, the bowels should be moved at least once daily, and, above all, active exercise out of doors, as far as practicable, should be systematically pursued. The natural alkaline waters should be used, both internally and by the bath, for one or two seasons ; those of Vichy Carlsbad and Marienbad are the best.

The great preponderance of biliary colic amongst females, as compared with males, has been remarked by most writers on the subject. Of the seven examples which I have given, the patients were females in five instances, and the great majority of the other cases which have come under my notice belonged likewise to the female sex. Furthermore, in every instance except Case V., the female patients were of the better classes. It is not unreasonable to conclude that the sedentary habits of ladies, and their highly artificial dietary, are, in a great measure, chargeable with this result.

(*a*) Abstract of a paper read at a meeting of the Medical Society of Dublin, February, 1876.

It will be observed that in this paper, which is of a purely clinical character, I have eschewed the pathology and the chemistry of gall-stones. The subject in its general bearings is much too large for a brief memoir. It has been adequately and ably treated by Fauconneau Dufresne, Frerichs, Trousseau, Prout, Budd, Murchison, and quite recently by Dr. Hilton Fagge, all of whose writings may be consulted with profit.

ACUTE ABSCESS OF TONSIL (RIGHT) IMPLICATING PHARYNGEAL APONEUROSIS AND PRESENTING BEHIND STERNO MASTOID.

By Frank Thorpe Porter, L.R.C.S.I., L.K. & Q.C.P.I.,
Demonstrator in Anatomy, Ledwich School.

The following case may perhaps be not devoid of interest.

The patient, a strumous-looking lad, aged 10, came under my notice on the 13th ult.

He complained of headache, rigors, pain in swallowing, and want of sleep. The tongue was dry and brownish on the surface, the skin hot and tense, the pulse 90, and peculiarly unsteady. On examining the throat I found a swelling the size of a walnut, hard, yet moderately fluctuating, on right tonsil. I prescribed small doses of the perchloride of iron, a purgative composed of calomel and pulv. rhei comp., and ordered an alum gargle. The following day the swelling became increased and elongated, extending externally along the posterior edge of sterno-mastoid for about four inches; the swelling was also much increased internally, and the patient could with difficulty swallow even fluids. This state of things was accompanied by muttering delirium. I then ordered two leeches to be applied over the upper and posterior part of sterno-mastoid, to be followed by *small* poultices *over* the *bites*. The following day (March 15) the swelling was much diminished, but fluctuation was distinct, and a small incision gave exit to about six ounces of pus.

Abscess of the tonsil is comparatively rare; it is still more so to find it take the course it did in this case. With reference to the treatment of such cases, I must disapprove of the custom of applying *large* poultices; they increase the *area* of suppuration often to an alarming degree. I have known a comparatively small abscess to attain the dimensions of a child's head owing to too great zeal in poulticing.

I may add that throughout the whole of this case there was no *rash* of any kind, although scarlatina was in the neighbourhood.

The patient is now rapidly convalescing.

ON TUBERCULOSIS IN CHILDREN AND THE CONDITIONS WHICH RESEMBLE IT.

By W. H. Day, M.D., M.R.C.P.Lond.,
Physician to the Samaritan Hospital for Women and Children.

(*Continued from page* 276.)

Sweating, which so certainly reduces the general strength, is a common feature in cases of phthisis, though it is not even a necessary feature here. Where the temperature remains persistently high for some time, and then begins to decline, sweating is met with. In cases of nervous exhaustion and general weakness it is to be anticipated, so that though it is not an invariable rule in phthisis or tuberculosis, the debility consequent upon either of these last conditions may produce it independent of elevation in temperature. The sweating that is due to a febrile condition of the body is generally noticed as the fever declines, and it thus becomes a natural and efficient means of reducing the fever without the aid of drugs; but when it comes on from sleep, or exertion, or fasting, it is due to exhaustion, and, unlike the sweating from fever, there may be several attacks in the course of the day. How far these conditons may co-exist—viz., fever and debility—is a point we cannot always easily decide, for in many cases of phthisis fever and debility are both at work, and it may be impossible to say what is due to fever, and what to debility, but, as the case advances, the difficulty is cleared up. Sweating, therefore, is a far less certain indication of tuberculosis than a persistent elevation of temperature, and where the latter condition exists, too much weight should not be attached to its importance as a significant sign.

Pulse.—Now the pulse is another and more valuable guide than sweating. As the temperature rises the pulse usually increases in frequency; but this is not an invariable rule, for the temperature may reach a high point, as 103 deg. or 104 deg., and yet the pulse remain slow, and the respiration also. After ovariotomy we have striking instances of this. I have repeatedly noticed the temperature, 102 deg., respirations, 16, and the pulse, 64. This indicates exhaustion and the danger of collapse. I am inclined to think that when the pulse and respiration remain slow, and the temperature goes on rising, the patient is often in a perilous position, and that more correspondence in the relations are preferable for a hopeful diagnosis, than when the variance is so great. The pulse, therefore, is no guide to the absence of fever, or the deposition of tubercle. Then, too, when the temperature is falling, debility and exhaustion may send up the pulse, so that this is not an infallible guide. Thus, recently, in a case of severe bronchitis, and a condition of the blood resembling pyæmia, when the temperature was 102 deg. the pulse was 96; when the temperature fell to 99° 2′ the pulse rose to 112; when the temperature fell to normal the pulse rose to 120. A nervous or hysterical temperament will accelerate the circulation without influencing the temperature, and this may deceive some persons if they are not aware of the condition. The pulse, therefore, as a guide to the diagnosis of tuberculosis, is of less value than the elevation of temperature. Dr. Wilson Fox says that an accelerated pulse is not constant in acute tuberculisation of the lungs. He contends that it may be less than 100 frequently, and in some fatal cases below 70 both in the morning and in the evening. When the disease is established or progressing the pulse is quickened. When it is slow, and accompanied by a low temperature, there is the greatest chance of the disease being arrested or cured. Of the relation between the morning and the evening temperatures, which are not without scientific interest and practical value, Dr. Fox found in 54 cases that the evening pulse was quicker than the morning in 20 cases; it was slower than the morning in 22 cases; the evening pulse equal to the morning in 12 cases. Of the mean pulses in 46 cases, the evening pulse was quicker than the morning in 28 cases; the evening pulse was slower than the morning in 12 cases; the evening pulse was equal to the morning in 6 cases.

In proportion to the severity of the disease does the respiration become accelerated, and that in the evening is somewhat in excess of the morning. Sometimes quickness of breathing is the chief but overlooked symptom in acute tuberculosis, and I should attach extreme weight to such a symptom, as I should also to oppression of the cardiac region and dyspnœa in rheumatic pericarditis before physical signs were present. The respiration, as may be expected, bears a close relation to the quickness and slowness of the pulse. In health they correspond, and in fever as the circulation is accelerated, the respiratory movements become more frequent; blood is transmitted with greater frequency to the respiratory centre, and stimulates it to discharge an increased amount of work. In double pneumonia, when the blood is more venous, the dyspnœa and respiration become so increased that by this symptom alone we judge of the perilous state of the patient. When the tuberculosis is intense, there is usually acceleration in breathing, and both in the morning and in the evening the respirations are above 30 in the minute. In 54 cases of the quickest pulse, the evening respiration was quicker than

the morning in 25 cases; the evening respiration slower than the morning in 23 cases; the evening respiration was equal to the morning in 6 cases. In 54 cases of the slowest pulse the evening respiration was quicker than the morning in 24 cases; the evening respiration slower than the morning in 17 cases; the evening respiration equal to the morning in 13 cases. Of the mean respiration in 46 cases, the evening respiration was quicker than the morning in 80 cases; the evening respiration slower than the morning in 20 cases; the evening respiration equal to the morning in 6 cases.

But regarding the rate of pulse to the temperature, as I have previously stated, there is no necessary relation. The temperature may be high, and the pulse slow, or *vice versâ*. We may have a morning pulse of 140 and the temperature 97 deg., the evening pulse may be 130 and the temperature 95 deg. or 96 deg. [Wilson Fox]. We must infer that the variation in temperature may be accompanied with a pulse of the same frequency; yet those cases which are distinguished by a rapid pulse are commonly those where the temperature is highest, and low pulses are generally met with where the temperatures are low. These conclusions of Dr. Fox accord with my experience of some other pyrexial states. Quick breathing may be associated with a slow pulse, and in exceptional cases slow breathing with a quick pulse. In one case of acute tuberculosis the quickest pulse was 136, and the respirations 28; the slowest pulse was 88, and the respirations 32. Some condition of the nervous centres due to hysteria or exhaustion may explain this.

The relation of the respiration to the pulse is more definite than it is to the temperature; the slow pulse is usually accompanied by retardation of the respiration, whether it be morning or evening, but the pulse may be slow whilst the respiration is rapid. The pulse is more influenced by the temperature than the breathing; a slow pulse and rapid breathing may coexist with low temperatures, but a quick pulse and rapid breathing may also be associated with low temperature. When the pulse and respiration are both low, the temperature is generally normal, or nearly so. Pyrexia may exist with little acceleration of either, or the temperature may be high, and the pulse quick, whilst the respiration is scarcely accelerated, and this applies to some other febrile states besides tuberculosis.

According to Dr. E. Smith and Dr. Fox, rapid pulses with slow breathing are not observed in the early stages of phthisis. For many of the foregoing calculations concerning the relations of the temperature, pulse, and respiration in tuberculosis, I am indebted to the perusal of Dr. Fox's paper on this subject, who has collected a large number of facts from his experience and that of others. (*a*)

The three following are among many similar examples which have come under my notice, from time to time, and at varying periods of the illness I have hesitated to decide whether I was not dealing with genuine tuberculosis.

Case I.—Jane C., aged 6½ years, first came under my care at the Samaritan Hospital, on October 24, 1874. She was an intelligent child, with fair hair and grey eyes, and of late had grown beyond her strength. During the winter of 1873 she had an attack of croup, and had been ailing ever since. Her father and mother are healthy, but a younger brother is the subject of rickets. The last month she had become much worse; she was too weak to take any exertion, and in the evening was feverish and hot, with a bright circumscribed flush on the left cheek. It was seldom observed on the right cheek. The chief symptoms complained of were pain in the stomach and constant sickness, so that she could retain nothing that she swallowed. She had a short, frequent, and troublesome cough, and expectorated a little thin phlegm: she complained of thirst and headache, and the tongue was covered with a thick white fur; latterly, she had become irritable and fidgetty, and it was difficult to amuse or please her. There was some obscure dulness under the left clavicle, but no harshness of breathing or moist sounds: the cardiac sounds were very distinct under both clavicles. The temperature was at 104°5′, pulse 160, respiration 40. I ordered the child to be kept in the prone position till the sickness was relieved, and to be fed with a tablespoonful of milk and lime-water, in equal proportions at a time. In the shape of medicine, citrate of potass was given im effervescence with hydrocyanic acid. She was to be sponged with tepid water in the evening, if free from pain, and to have a grain and a-half of quinine in a powder at bed-time before the paroxysms were expected.

27th.—The child was better, but the flushing had continued regularly morning and evening till this morning, when it was not observed: any fatigue or excitement will bring it on; the sickness and pain in the stomach are abated, she sleeps quietly at night, and makes no complaint of headache; the tongue is cleaning at the tip and edges; pulse 96; temperature 99 deg. As the bowels are inclined to be costive, and the motions green, I prescribed a powder at bed-time, consisting of hydrargyrum cum creta, sesquicarbonate of soda, and powdered rhubarb, of each two grains.

Nov. 10th.—She was much better, having had flushing of the face only twice last week on the same day; the sickness is completely arrested, and the bowels now act regularly every morning; the tongue is clean, and she is bright and animated; pulse, 92; temperature, 99°1′; respiration, 24; urine clear. When the fever declines she is to take the quinine powder three times a day. Since the last visit, she has taken a pint of milk daily, besides beef tea and mutton broth.

24th.—She had much improved till within the last few days, her cheeks having filled out, and her appetite amounting to hunger. The temperature is now only 98 deg., the pulse is 140, and this probably from nervousness, as an attempt at examination is enough to cause flushing. Last week she had flushing of the left cheek from over-excitement at play; to-day the left cheek is flushed; it has been noticed on both, but generally on the left—never on the right cheek alone. She spits up a good deal of phlegm, and often has the feeling of wishing to clear her throat—the bowels are quite regular. Since her illness began, she is generally restless in her sleep, and at these times is always flushed—the abdomen is increasing in size, and her clothes came together round the waist with difficulty. The mother noticed this swelling for the first time last week. The region of the liver is smooth, but slightly projects below the ribs, and the belly generally is tumid and protuberant, though free from pain and tenderness. She was ordered a teaspoonful of cod-liver oil twice a day, and as much nutriment as she could digest comfortably.

On December 8th the report states that the bowels had become very loose, the motions being dark and ragged-looking; she complained of pain in her eyes, and there was headache; since the diarrhœa began there has been more flushing, which keeps to the left cheek; the abdomen still increases in size, and the frock will not come together. There is more cough and some dulness below the spine of the left scapula, with mucous rhonchus. The mother refused the child to be admitted as an inpatient, and I did not see her again until November 6th, 1875, when I ascertained on calling at her house the following facts. After her last visit she remained ill for about a month, and then gradually regained her flesh and strength, and her body returned to its normal size. The medicine was continued regularly during this time. The chest now expands well, but the percussion note does not appear to be quite so clear on the left side as on the right, and there is dulness in the supra-scapular space of the same side, but no moist sounds anywhere. There is no enlargement of the liver or spleen, and the belly is soft and natural. Allowing for some excitement at my

(*a*) *Medico-Chir. Trans.*, Vol. lvi., 187?.

unexpected visit, I found the pulse did not exceed 84, respiration 24, temperature normal. The child is in every respect healthy, and goes to school regularly. I see no reason to deny the possibility of a deposit of tubercle in this case, and the fall of temperature to indicate its arrest, if not its cure, but the rapidity of the fall scarcely justifies the hypothesis. If the tubercular deposit remains small, there is no reason why it should give rise to any symptoms.

Case II.—P. E., aged 12, was first brought to me on the 19th of April, 1875; he is the son of healthy parents residing in an elevated district in the neighbourhood of London, and has five brothers and one sister. The eldest brother died at fourteen years of age of heart disease, apparently unconnected with rheumatism. He has always experienced fair health until six weeks since, when he took cold and had feverish symptoms at his school in Staffordshire, where the atmosphere is damp and humid. His illness was thought to be whooping-cough, but this is doubtful, as no medical man was consulted, and since his return home his parents have never heard him whoop. His second brother, who went to the same school, was lately seized with rheumatic fever, and died there. He has lost much flesh, and is now very thin, his clothes hanging loosely on him. He is a slender and delicate lad, with downcast eyes, and a sad, wearied expression; the veins are very prominent and distended over the front part of the chest, and the spine is much curved from weakness, the lower angle of the right scapula being within an inch of the spine—the left is three inches from it. Phthisis is not hereditary, and no member of the family on either side appears to have suffered from it. The symptoms complained of were great langour and prostration of strength; he had little inclination to enter into any amusement with his brothers, and if he did he was soon fatigued, and glad to lie down. He has a short, frequent, hoarse cough, and spits up a little light tenacious phlegm in the day-time, but more particularly in the morning, on waking. Towards evening he gets flushed, and complains of headache and thirst; his mother notices that he is restless in his sleep, and that the skin is hot and not sweating. On examination of his chest, the expansion is good and equal under both clavicles, though, in consequence of his having lost so much flesh, the depressions above and below the clavicles are very marked, and the shoulders are rounded and bent forward; the percussion note is resonant, and the vocal vibration is greater than usual, but this is explicable on the ground of the thoracic walls being so thin, and the intercostal spaces everywhere depressed.

A similar reason may explain the loud and rather harsh character of the respiration under both clavicles, but there were no moist sounds. On percussing the back the dulness was greater in the supra-spinous fossa on the left side than on the right, but in the absence of submucous or sonorous rhonchus, the result of this physical examination did not enable me to pronounce the patient tubercular when I was pressed for an opinion. I thought he was, and that in the course of a short time I should detect unmistakeable evidence of such pulmonary changes that all doubt would be set at rest. The skin was dry and harsh, the temperate 102°, the pulse 136, the respiration quiet, bowels costive, urine clear and non-albuminous; the tongue presented a whitish coating, and the appetite for food was imperfect, which in genuine tuberculosis is sometimes craving and voracious. I ordered him a diet of beef-tea, milk, and eggs, and he was to have cocoa instead of tea. In the shape of medicine, two grains of quinine were prescribed, morning and evening, and a syrup composed of squill, senna, and poppy, to soothe his cough and keep the bowels soluble.

May 13.—He looks marvellously better, being fuller in the face and more animated; he has coughed less, and never gets flushed in the evening; his appetite is greatly improved, and he rests well at night; pulse 112, respiration 24, temperature 98°. For the last three days he has complained of pain in the right side, below the nipple, which is increased on coughing or taking a deep inspiration, but as auscultation reveals nothing abnormal, the pain is probably neuralgic or muscular. The chest sounds are the same as at last report, but there is some laryngeal irritation and hoarseness. He was ordered to apply a warm poultice to the side at night, and to have a sponge bath with Tidman's sea salt every morning. A mixture to be given three times a day containing hypophosphite of lime, quinine, strychnia, and tincture of perchloride of iron was substituted for the simple quinine mixture.

On June the 9th the laryngeal irritation had not lessened, and the cough was hacking and troublesome in the morning, but unattended with expectoration; there was no sweating, and he slept well. Nearly three months later (at the end of August), after gaining flesh and going on remarkably well, he became faint and languid, and lost his appetite from indiscretion in diet. He was irritable and fretful, and nothing went right with him, which was attributable in a great measure to over fatigue and excitement in the hot weather. His voice is now clear, and he does not suffer from cough or laryngeal irritation. The chest sounds are normal. He derived the greatest benefit from the hypophosphites, and a month later he went to Brighton, where he is at school in perfect health.

I might relate other cases of a mixed and puzzling character, allied to genuine tuberculosis in many of the local and vital symptoms. If the lungs and other organs appear free from the deposit of tubercle at the time a patient comes under observation, we may pronounce the illness as simple and uncomplicated, and give a favourable opinion, because recovery, so far as I have been able to trace the progress of the disorder, has eventually followed the continuance of a class of symptoms which have borne the closest connection with what appeared to be at one time an irremediably hopeless condition.

(To be continued.)

Clinical Records.

CASES IN PRACTICE.

Reported by John W. Martin, M.D.,

Assistant Surgeon, Mayfield Factory Dispensary, Portlaw, &c., &c.

Case XV.—*Amenorrhœa—Headaches—Dyspnœa—Area of Heart's Dulness enlarged—Impulse at the Apex lost, but felt over the Base, accompanied by frémissement—Pericardial Friction Murmurs—Treatment—Recovery.*

M. A., æt. 17, factory operative, unmarried, a well-nourished, strong, healthy-looking girl, presented herself at the dispensary, Feb. 7th, 1876, giving the following history of her case:—

Never had a day's illness previous to July, 1875. About that time she was subjected to severe mental distress and anxiety. Her menstrual periods, which had previously been regular, ceased altogether, and have never since appeared. No suspicion whatsoever of pregnancy in the case. The only evidence that could be adduced in favour of the existence of the rheumatic dyscrasia, was an occasional pain in the left knee, of a sub-acute character, attended by slight effusion into the joint, recurring at intervals of six months, but never sufficiently intense to prevent her following her usual avocations.

In the commencement of November last, she felt for the first time a slight pain in the chest, in the region of the heart, accompanied by headaches of a not very acute type. Beyond the ordinary risks of exposure to wettings, variations of temperature inseparable from her occupation, draughts, &c., &c., she can assign no special cause for her illness, except the mental anxiety before men-

tioned, and subsequent stoppage of menstruation. The onset of the pain in the chest was very gradual, and week by week grew steadily worse. She does not remember having had vomiting, rigors, or other constitutional disturbance in the commencement of the attack. She had presented herself occasionally at the dispensary, but the symptoms of which she complained appeared to be dyspeptic in their origin; they were, costive bowels, loss of appetite, headaches, and pain, which she described as abdominal. She was actively treated for dyspepsia, without the slightest relief. She never at any time complained of tenderness to pressure over the heart. On Feb. 7th, 1876, when suspicion was first excited in my mind that the heart was engaged, the following were the symptoms of which she complained. Pain in the region of the heart, especially severe at the ensiform cartilage; complete loss of appetite; great inconvenience experienced after meals, owing to a sense of over-distension about the stomach, and pressure upon the heart. Sometimes the taking of food was attended by an inclination to vomit. The intermitting headaches from which she formerly suffered had become constant and much increased in severity. Tongue dry; bowels costive, acting only under the influence of medicine. Exertion of any description induced severe dyspnœa. Area of heart dulness most extensively enlarged; extending upwards as far as the lower border of the second rib, on the left side, and from that downwards for six inches in the vertical direction; the examination being made when the stomach was empty; its horizontal diameter extended from a point one inch to the right, of the right margin of the sternum, to a point one and a-half inches external to a vertical line drawn through the left nipple.

The heart's impulse could neither be seen or felt at the apex, but its action could be felt, accompanied by a strong *frémissement*, midsternum, opposite the articulation of the fifth rib. First and second sounds present, of equal length, resembling very much the action of the fœtal heart. On first placing the stethoscope over the heart I thought there was a great disproportion between its action and the number of beats in the radial pulse; the latter was only 96, very weak and compressible, and gave me the idea of a slow pulse; whilst the former seemed to be going at a gallop.

On reckoning the number of beats, however, in each case, they were found to correspond. First sound very weak, and indistinct at the apex, heard more strongly towards the base; second sound greatly accentuated, heard loudest opposite the articulation of the third and fourth ribs, and at the right margin of the sternum; the accentuation was much less marked on the left margin.

A loud well marked "*frottement*" was heard over the whole cardiac region, of equal intensity throughout. There was no congestion of the veins of the neck. Respiratory system normal. Passed an abundance of urine, free from deposit, sugar or albumen. The optic disc in both eyes was very pale, and presented what appeared to be a double margin, the arteries were very small and the veins distended; the retina had a finely mottled appearance. She had, however, no pain in her eyes, and her sight was excellent. I directed a blister 4 × 4 to be applied over the heart, and prescribed—

℞ Potass. iodidi, ℥i.;
Potass. bicarb., ℥ij.;
Tr. aconiti, ℥iss.;
Syrupi, ℥i.;
Aqua ad ℥viij. M.

Two tablespoonsful to be taken every fourth hour.

Feb. 13th.—Did not apply the blister as directed, her mother thinking that she was not strong enough. Took her medicine regularly. Felt better; almost free from the palpitation, headache, vertigo, and dyspnœa. She felt able to undergo a much greater amount of exertion. There was slight diminution in the area of heart dulness; the first sound was stronger, but still masked by the friction murmur, which had become much softer and finer; the second sound was very strongly accentuated, the accentuation being heard over the whole of the base of the heart, opposite the articulation of the fourth rib, and of equal intensity at both margins of the sternum. Pulse 100, its tone being much improved. Looked, and expressed herself as feeling, much better. I repeated the mixture, and recommended the application of the blister.

Feb. 18th.—Blister applied, followed by a very free discharge of serum. Much stronger and better. Heart dulness diminished to an area two inches in diameter; its action stronger, quite regular, and both sounds distinct. First sound, no longer masked by the murmur, which was very faint and soft; second very much less accentuated than it was on the previous visit.

℞ Potass. iodidi, ℥i.;
Potass. bicarb., ℥ij.;
Tr. digitalis, ℥iss.;
Tr. cinchonæ, ℥ss.;
Sp. am. aromat., ℥ij.;
Infusi cinchonæ ad ℥viij. M.

Two tablespoonsful to be taken three times a day.

Feb. 28th.—Improved in every respect. Received permission to return to work. Murmur very faint and indistinct. Heart's action and sounds normal. Area of dulness remained as last noted, having a diameter of 2 × 2 inches. I continued her treatment, and directed her to present herself occasionally for further observation.

March 24th.—This patient has never since attended dispensary, or come under my notice. I may fairly presume her health remains good.

The following points are worthy of notice in the foregoing case:—

1st. Coincidence of mental anxiety, and the cessation of menstruation, with the subsequent lapse of several months before the appearance of the pain felt in the region of the heart.

2nd. Quiet onset of this pain, unattended by any soreness, or tenderness to pressure over the heart, or febrile constitutional disturbance, such as rigors, vomiting, &c., &c.

3rd. The very slight evidences that existed of the rheumatic dyscrasia.

4th. The great extent of dulness, reaching upwards as far as the lower border of *the second rib*, and from *one inch to the right* of the right margin of the sternum, to a point one and a-half inches *external to the left nipple line*, together with the weakening of the first sound, indicating extensive effusion into the pericardium.

5th. Apparent disproportion between the action of the heart and the radial pulse; no such real disproportion however existing.

6th. The fact that the first sound was heard at all at the apex, where such extensive effusion existed; in many cases that have fallen under my notice in which the effusion into the pericardium was much less, the first sound has been lost completely.

7th. Accentuation of the second sound, taking into account the cessation of the *menses*, and the gradual onset of the disease.

8th. Absence of any congestion of the veins of the neck.

9th. Appearances presented by the fundus of the eye, *i.e.*, absence of redness in the optic disc, in the presence of venous distension, which was very strongly marked. The double margin to the disc is also worthy of note.

This patient's rapid recovery under treatment was very satisfactory. I deem the case an interesting one, from the insidious manner in which it developed itself, and therefore have been careful to dwell upon the negative as well as the positive evidences, as to the nature of the morbid changes present, and the history of their development.

Transactions of Societies.

CLINICAL SOCIETY OF LONDON.

LINHART'S CHISEL FOR EXCISION OF BONE.

Mr. T. HOLMES related the particulars of a case, for the purpose of introducing Linhart's chisel to the notice of the meeting. The patient, a married woman, aged 45, had had swelling and pain of the left ankle for three years, these symptoms having gradually increased. An incision being made over the front of the joint, the astragalus was found to be diseased, and the end of the tibia eroded. Subsequently, an operation was performed, upon Esmarch's bloodless principle, and with the minutest details of the antiseptic plan. The astragalus was removed with the lion forceps, and the lower ends of the tibia and fibula were excised with Linhart's chisel. The wound was then thoroughly dressed antiseptically. Pus, however, formed within it, and had to be evacuated. At the date of Mr. Holmes's communication (two months after the operation), the wound was almost cicatrised. This chisel, invented by Herr Linhart of Würzburg, was a stout instrument with an oblique edge, having a thick back, on which was a projecting ridge to catch the hammer, by which the weapon was driven through the bone. It could be driven with an equable motion through the bone in the same straight line as that originally formed by its edge, and could be stopped at the proper place. It never splintered the bone, and required no dissection around the bone to be removed. It would prove a valuable acquisition to the surgeon's stock of instruments, but required a moderately firm basis for the bone to be divided, and might possibly not always prove sufficiently powerful to deal with very much solidified bone.

Mr. PICK referred to its use in three cases, one of exostosis, one of necrosis, and one of the removal of a part of the lower jaw. He had failed to find it of service in the last case, owing to a want of support of the bone which was requisite when the instrument was used.

Mr. MAUNDER remarked that doubtless those who had used the instrument were more capable of speaking as to its merits than he who had not used it; but it certainly seemed to him that, owing to its oblique edge, there would be considerable danger of the instrument leaving the bone and injuring the soft tissues whenever struck by the hammer; he could not see the advantage of the chisel in question over the ordinary chisel which he was in the habit of using.

HEADACHE, DOUBLE OPTIC NEURITIS, AND BLINDNESS, ENDING IN RECOVERY.

Dr. GOODHART read notes of this case. The patient, aged 21, had been under the observation of Mr. Higgins and himself for more than a year. She had suddenly been seized with severe headache and vomiting in December, 1874, and gradually in the course of a few days became completely blind. She had also attacks of dyspnœa, pain, and slight hyperæsthesia on the right side of the head and neck, incomplete paralysis of the external rectus of each eyeball; very transient left hemiplegia following a severe attack of headache, indistinctness of articulation and slight mental disturbance, while constipation and a slow and irregular pulse marked the whole course of the acute attack, which extended over a fortnight. The temperature was not raised. Since that time she had slowly recovered, and had now for some time past resumed her occupation, that of a teacher in one of the School Board schools. Her sight was still far from perfect, and there was a tendency to retch unless she was very careful with regard to the quality and quantity of her diet. She was treated by the assiduous application of cold to the head, and by iodide and bromide of potassium, with small doses of mercury and chalk internally. The authors brought the case forward with a view to elicit opinions on the diagnosis. From the sudden onset of the symptoms, the early optic neuritis, and the absence of any pyrexia, they inclined to the view that the disease was one implicating the substance of the encephalon rather than the membranes. A tubercular family history, the appearance of the patient, and some history of a previous blow led up to the conclusion that the affection was probably a yellow tubercle, while the symptoms narrated indicated that the lump was a small one situated on the right side more than the left, at the upper part of the pons Varolii. The occurrence of temporary hemiplegia after a severe attack of headache, and the persistence of a tendency to retch long after all urgent symptoms had subsided were also noted as interesting features in the case.

Mr. COUPER said that recovery after almost complete loss of sight was not rare. He referred to the case of a boy suffering from albuminuria with double optic neuritis. The optic disc was surrounded with opaque exudation and streaks of hæmorrhage, for several days he was almost blind, but he recovered sufficiently to read No. 6 Jaeger's tests. Though improvement took place to such an extent, the condition of the fundus of the eye did not change.

Dr. GREENFIELD said Mr. Couper's case was not similar to Dr. Goodhart's. Mr. Couper's case was one of albuminuric retinitis and amaurosis, such as occurs in Bright's disease, whilst in Dr. Goodhart's case the symptoms were probably due to optic neuritis extending back to the brain.

Mr. MACNAMARA remarked that one should be careful in forming a prognosis from the ophthalmoscopic appearances. In sunstroke the disc was frequently covered with exudation, but the sight improved as the exudation diminished. Sometimes when the effusion was great the vision was only slightly diminished. He thought the symptoms and course of the disease in Mr. Goodhart's case were such as would occur with syphilitic gummata.

Dr. BUZZARD said he had not heard the whole description of the case, but having asked the patient a few questions, he had but little hesitation in asserting, from his experience in similar cases, that the symptoms were due to a tumour of syphilitic origin, such as a gummatous deposit. The cure by iodide of potassium tended also towards this view. With regard to the question of choked disc and optic neuritis, he thought it was impossible to distinguish them.

To this last statement Mr. LAWSON remarked that the two conditions were totally different.

Dr. GOODHART, in reply, said that he protested against Dr. Buzzard's opinion. He had made every inquiry, and found no suspicion of syphilis; and as to the case being doubtless syphilitic because it was relieved by iodide of potassium, he might remark that pleuritic effusions and strumous diseases were also relieved by that drug.

OBTURATOR FOR CLEFT PALATE.

Mr. A. T. NORTON related particulars of a case of cleft prlate in a child, thirteen years of age, in which the cleft extended forwards to the alveolar border, whilst posteriorly the two halves of the uvula could barely be made to approximate. After the operation, union took place in the uvula and soft palate and in a large portion of the tissue covering the hard palate; but in the front of the mouth there still remained a space five-eighths of an inch in length by half-an-inch in breadth; and the voice was not at all improved. With a plate over the aperture between the nose and mouth, a slight improvement was perceptible; but the uvula was not capable of sufficient movement, so as to lie against the pharynx and close the aperture upwards to the nostrils. With Mr. Sewill's assistance, an obturator was devised and made, to which was attached a false uvula of considerable breadth, and composed of flexible vulcanite india-rubber, protruded backwards from the nose into the pharynx. This apparatus effectually closed the passage to the nose when the child spoke, and she could immediately articulate the letters S and Z to perfection, sounds which she had before been quite unable to make. It was found necessary to have the part of the obturator which connected the mouthplate with the nasal rim made slightly smaller in size than the aperture to which it was fitted, otherwise pain was produced. There was so little development of bone in this case that the two sides could not have been brought together by Sir W. Fergusson's operation. Mr. Norton thought this instrument would be of great use in other similar cases, where the uvula could not be made to close with the pharynx the passage between the buccal and nasal cavities.

Mr. MASON remarked that Mr. Norton had spoken of division of the soft palate at its outermost part being of but little service in the improvement of the voice. He could say from experience that by this operation the soft palate became, in fact, one large uvula capable of considerable movement, and

regardless of how it might be explained, the voice was always much improved.

Mr. THOMAS SMITH wished to know if the obturator were made in two pieces, and if the patient could easily apply it.

Mr. NORTON, in reply, said that the obturator was made in part of hard vulcanite, and in part of a soft flexible vulcanised india-rubber, but that in the manufacture they were united into one piece. The method of insertion was simple and easily carried out by the patient. The protruding false uvula was first passed through the aperture in the hard palate up into the nose, and then by gentle pressure upwards the whole instrument readily found its way into position, and was there retained by a flexible nasal rim.

HYDATID TUMOUR OF THE ORBIT.

Mr. LAWSON read the report of a case of large hydatid tumour removed from the orbit. The patient was under his care at Moorfields Hospital in October, 1872, suffering from protrusion and eversion of the left eye, with impairment of vision. There was proptosis of the left eye to about half an inch beyond the orbit, with complete divergence. A soft mass could be felt at the upper and inner part of the orbit, which had a sense of fluctuation. The field of vision was normal, and he was able to count his fingers at the distance of a foot. The optic disc presented the appearance of "choked disc." The swollen nerve seemed to stand out from the fundus, and the vessels of the fundus were extremely tortuous, especially the veins as they passed over the margin of the papilla. Mr. Lawson punctured the tumour through the upper eyelid, and drew off two drachms of clear fluid. The patient was not seen again till February 14th of this year, when he was admitted into the hospital for the removal of the greatly increased tumour. The protrusion and everion of the eye were much increased, and the sight so impaired that he could only distinguish shadows. The upper eyelid was cut through so as freely to expose the tumour, and it was then punctured and a quantity of clear water escaped, and with it two or three small daughter cysts. The parent cyst was drawn out entire by forceps. The wound uppurated, and the eye immediately began to recede. The patient left the hospital in the following week. He could then readN o. 20 of Jaeger's types. Mr. Lawson referred to the extreme rarity of cases of hydatid cysts in the the orbit. He believed that there was only one other on record in England, a case of Mr. Hulke's, of which the preparation is in the Middlesex Hospital Museum. He added that the choked disc was produced by the presence of a tumour on the optic nerve, and that the disc assumed its normal appearance on removal of the pressure by tapping the cyst. It had been long known that tumours pressing on the optic nerve would produce choked disc, but in no case had he seen the fact so clearly demonstrated.

Vital Statistics.—From the Registrar-General's return we learn that during last week 6,041 births and 4,014 deaths were registered in London, and twenty-two other large towns of the United Kingdom. The mortality from all causes was at the average rate of 26 deaths annually in every 1000 persons living. The annual death-rate was 25 per 1000 in Edinburgh, 24 in London, 31 in Glasgow, and 35 in Dublin. The annual rates of mortality during the same period in the other large towns were—Norwich 21, Hull 26, Leicester 20, Sunderland 18, Portsmouth 33, Newcastle-upon-Tyne 19, Birmingham 21, Brighton 22, Leeds 25, Wolverhampton 23, Bradford 26, Sheffield 23, Plymouth 26, Bristol 27, Oldham 34, Manchester 34, Salford 37, Nottingham 27, and Liverpool 34. The annual death-rate from the seven principal zymotic diseases averaged 3·7 per 1000 in these towns, and ranged from 0·9 and 1·2 in Leicester and Oldham, to 7·1 and 8·3 in Portsmouth and Salford. Eleven more deaths were referred to small-pox in Manchester and Salford; and scarlet fever showed an increased fatality both in Salford and Bradford. In London, the 1,581 deaths included 37 from scarlet fever, 22 from different forms of fever, but not one from small-pox; the seven principal diseases of the zymotic class caused 225 deaths, against 223 and 234 in the two preceding weeks. These 225 deaths were 19 below the corrected average number from the same diseases in the corresponding week of the last ten years. Different forms of violence caused 54 deaths; 48 were the result of negligence or accident, including 19 from fractures and contusions, 4 from burns and scalds, 5 from drowning, one from lead poisoning, and 13 of infants under one year of age from suffocation. Six of the deaths from fractures and contusions were caused by horses or vehicles in the streets; from this class of accident 79 cases of injury and maiming came under the notice of the Metropolitan and City Police during the seven days.

RECENT REPORTS ON CHOLERA.—CONDITIONS OF ITS TRANSMISSIBILITY.—No. I.

IT is a disheartening reflection that the success which has attended the investigations of medical men into the origin and nature of cholera is by no means proportionate to the enormous amount of labour and research that has been devoted to the subject. In a series of Reports, which has been published under the direction of the United States Government, Dr. John S. Billings has given the profession a more complete Bibliography of Cholera than has ever been compiled before, either in this or any other country. That medical literature was rich in works on one of the most appalling and most fatal pestilences of modern times our readers were, we dare say, quite prepared to hear. But we are much mistaken if they are not somewhat surprised to find that a catalogue of the various works, reports, &c., which have been published on this disease alone occupies more than 300 large octavo pages. The great disproportion, however, between the means used and the end obtained is not so difficult to account for. It is only recently that the profession has turned from theory and loose observation to experiment and systematic research. It is only recently that, by more earnest inquiries into the conditions by which cholera is propagated, and into the means by which it may be prevented, that we have somewhat compensated for the valuable time that has been wasted in theorizing as to the nature of that disease, and in futile attempts at its treatment. It is only within the last few years that much progress has been made in State medicine, and that it has been thought worth while to send into the field of sanitary investigation men who by their acquirements are specially fitted to grapple with the difficult problems

connected with the origin and prevention of epidemics. These reforms, however, taken in connection with the great international interest that is being taken in the matter, and the exertions of our own Goverment, justify us in looking forward to a time when cholera will be almost stamped out in India and comparatively unknown in other parts of the world.

This important subject naturally divides itself into the conditions which render cholera endemic in India, and into those which propagate the disease to other countries. Among the latter conditions, the influence of human traffic is well known, and we cannot say that the reports recently published have, on this point, added much to our information. It is impossible to peruse the elaborate reports that have been respectively published by the English and American Governments without noticing how much labour and research have been spent in going over the same ground as was gone over 20 or 30 years ago. As Mr. Simon observes, the practical results of Mr. Netten Radcliffe's able and exhaustive report consist in the facts which bear upon the influence of human intercourse in determining the diffusion of cholera, and secondly in the inferences which arise with regard to the virtual illimitability of that influence (as between Asia and Europe by measures of the nature of quarantine.

Before, however, we go any further, we must pass a few remarks on a question about which there still appears to be much confusion of thought. We allude to the question of contagion. It is remarkable that Professor Pettenkofer, whose researches on various sanitary subjects have gained for him an European reputation, while admitting the great part played by human intercourse in the diffusion of cholera, has nevertheless "the gravest doubts as to the contagiousness" of that disease. He even enters into arguments against the theory of contagion. He asserts that cholera radiates more from infecting neighbourhoods than from infected individuals; and he accounts for the cases in which the disease appears to arise from contagion by saying that all the facts can be explained "on the assumption that the patient had conveyed with him from the cholera district so much of the cholera poison that there was enough to infect the other persons who were attacked." We need not say, however, that every page of these reports teems with evidence of the contagious or infectious nature of the disease; and we are not surprised to see our own able pathologist, Mr. Simon, admit that such is the case. "Detailed observation," he observes, "of particular outbreaks of cholera, and suggestions of analogy and experiment, have long led European pathologists to believe that the disease possesses great though peculiar power of spreading from the sick to the healthy; and Mr. Radcliffe . . . furnishes only additional illustration of that now (as I believe) unquestionable doctrine." We need scarcely observe that these conflicting statements are but the latest expression of that difference of opinion which has long divided the profession with respect to the contagiousness or non-contagiousness of cholera. How then are we to account for this discrepancy of opinion? It no doubt partly arises from the different sense in which the term "contagion" may be and is employed by different writers. Those who limit the application of this term to those cases in which a disease is contracted by the healthy coming into direct contact with the sick are perfectly justified in saying that cholera is not contagious, as there is the strongest evidence in favour of that view. If, on the other hand, we use the term in a more comprehensive sense, and with due regard to its derivative signification, then we are, in face of all the evidence at hand, perfectly justified in calling cholera a contagious disease. For it is admitted on all sides that a patient contracts cholera by coming into *contact* with the cholera-germs either through the medium of the air he breathes or the water he drinks—and what is this but contagion? It would, however, be as well, in all future writings and discussions, to avoid the term altogether; and we think the Vienna Conference acted very wisely in adopting this course, and in framing their propositions without mentioning the word at all.

TRAINED NURSES FOR THE POOR.

Some weeks ago we endeavoured to place prominently before the profession and the public the claims of an institution for providing trained and educated nurses for the sick poor. We now desire to call more particular attention to the efforts of Miss Florence Nightingale, directed to the same end. This lady, it is well known, was among the first to show how much more efficiently an educated person could carry out the duties of nursing the sick, and through her earnestness a new era dated from the termination of the Crimean war in training and preparing educated women for the important duties of nursing. In a letter to the *Times* last week, Miss Nightingale endeavoured to enlist public sympathy and support in her benevolent work. It is quite certain that we cannot find good nurses ready made to hand, and it is worth some trouble and expense to give those willing and ready to engage in nursing a regular training for their work, so that when called upon they may be ready to act with a full knowledge of all the requirements and needs of any special class to which they may be called—ready, in short, to undertake for the poor the preparation of nourishing food, as well as the administration of the medicine, to see to the regulation of the household, the sanitary condition of the surroundings, and the improvement of the family, for while a mother is on a bed of sickness, there is often no one to see to these things. But withal, we must not expect too much of the nurse; we must not try to convert her into a maid of all work; neither can we expect the nurse on her return home, "dog tired," from her patient, to do everything for herself. Nursing requires her undivided attention, and all the health and strength both of mind and body. If, then, she has to provide for herself, she can only be half a nurse: and it is then one of two things. Either she is of the level of her patients, or she sinks to the level of her patients, and actually makes apologies for their dirt and disorderliness, instead of remedying them Nay, as the old hospital nurse did thirty years ago, she may even come to prey upon what is provided for her patients. But no woman really t for the work will do

both, nor ought she to do it. To have a person fit to live in a home—and to create homes for the poor—for it is nothing less—you must have a home fit for her to live in. If you give nurses a bad home, or no home at all, you will have only nurses who will live in a bad home. They forget what a home is. How, then, can they reform and recreate, as it were, the homes of the sick poor?

The very thing that we find in these sick poor is that they lose the feeling of what it is to be clean. The district nurse has to show them their room clean for once—in other words, to do it herself; to sweep and dust away, to empty and wash out all the appalling dirt and foulness; to air and disinfect; rub the windows, sweep the fireplace, carry out and shake the bits of old sacking and carpet, and lay them down again; fetch fresh water and fill the kettle; wash the patient and the children, and make the bed. Every home she has thus cleaned has always been kept so. This is her glory. She found it a pigsty; she left it a tidy, airy room. In fact, these nurses are so far above their patients that the poor are "ashamed that we should see their homes dirty again."

How have the tone and status of hospital nurses been raised? Chiefly by making the hospital such a home as good young women—educated young women—can live and nurse in; and, secondly, by raising hospital nursing to a profession by which an honourable livelihood can be earned. How much more then is the same necessary for district nursing, where the nurses have to be out in all weathers, and where must be created, for there is not now, the *esprit de corps* which inspires the nurses of a good hospital and training school as it does the soldiers of a regiment of many battles and well-worn colours, whose glory must be kept untarnished!

Even now, except in some remarkable instances, the hospital nurse wants more and gets less of the helps, moral, material, and spiritual, than the woman in a good home or service. The district nurse wants yet more than the hospital nurse, for her life is harder and more exposed, and she gets none.

A start has, however, been made to give to the London district nurse the real help and the real home which are the secret of the success of active religious sisterhoods abroad, together with the real independence, enterprise, indomitable self-reliance, and capability of training the powers to the best efficiency, which are the secret of the success of the highest British character, and all of which are wanted in the crusade against dirt and fever—the crusade to introduce light and air and cleanliness into the worst rooms of the worst places of London.

Notes on Current Topics.

The London Water Supply.

Dr. Frankland reports of the water supplied to the metropolis during the past month, that both the Thames and the Lea waters were much polluted by dissolved organic matter. They have not been in so bad a state since November last. The water supplied by the Chelsea Company was turbid after filtration, and that of the Southwark, Grand Junction, and Lambeth Companies showed inefficient filtration. The water drawn from the mains of the Lambeth Company contained matted fungoid growths full of moving organisms. The Southwark Company's water contained blue cotton fibres and numerous living organisms. A curious instance of the doubtful state of the London water supply was lately given by a correspondent of *Land and Water*, who found a considerable number of live perch and roach in a gasholder tank which had been filled some months previously with water from the mains of the Southwark and Vauxhall Water Company. Of course the gasholder tank had not been used in the interval, or we should have a curious comparison brought about between the relative merits of "pure" and gas-polluted water. But as it is, the case suggests strange reflections on the potability of such water. The fact that fish will live and thrive in it may be urged as a proof of its purity; but, on the other hand, what is the fishes' food may be man's poison.

Poisoning by Water Hemlock.

Several children have been poisoned at Stockton-on-Tees, and two have died. It appears that a man named Kindler found some roots which he thought were parsnips. These he put into his pocket. By some means, not yet explained, a portion of the roots were eaten by several children, who became ill, showing symptoms of poisoning. On the one hand, it is stated that the children must have taken the roots from Kindler's pocket, while on the other it is asserted that he gave them the poisonous herb, which is said to be water hemlock. Kindler is in custody.

Horse Taming by Electricity.

Mr. George Laycock, farmer, of Whittington, near Sheffield, was recently convicted in the penalty of 40s. and costs, by the Sheffield Stipendiary, for cruelty to a mare, which he was taming by electricity at a public sporting ground. Horse taming by electricity in Yorkshire has, it is said, been freely practised of late, and the prosecution therefore excited considerable interest.

Seats for Saleswomen.

A ladies' committee in Manchester has caused a circular to be forwarded to all local shopkeepers employing female assistants, urging upon them the propriety of providing seats for their saleswomen when not engaged in serving customers. The document has been approved of by many members of the medical profession.

The Abuse of Opium in America.

We observe the statement in an American paper that the habit of opium-smoking in the Chinese dens of Virginia city is becoming so common among the white people that many of the older pupils in the public schools are beginning to frequent these places, and a loud call is made to have them closed by law.

Dr. Mattison, in an article in the *Medical Record*, maintains that, while alcoholic intoxication is decreasing

throughout the United States, opium-drunkenness is increasing, and the dealers in crude opium and the manufacturers of its alkaloids assert that the importation of the one and the productions of the other are rising rapidly year by year; so much so regarding morphia, that at one of our largest manufacturing centres the supply is said to be insufficient for the demand.

Absence of Tannin in Gentian Root.

At the last meeting of the Philadelphia Pharmaceutical Society, Prof. Maisch read a paper on "The Asserted Presence of Tannin in Gentian Root," clearly showing the absence of tannic acid in this drug. The infusion is not at once precipitated by gelatin, and yields, with a chemically neutral solution of ferric chloride, a blackish colour, due to gentisic acid, and to a body producing a green fluorescence, the colour being, of course, destroyed by an acid from the decomposition of the ferric gentianate.

Vomiting of Pregnancy cured by Hyoscyamia.

Dr. Pitois, Professor at the Medical School at Rennes, reports two striking cases of this. After trying, unsuccessfully, all the usual means, it occurred to him to administer a teaspoonful every hour of a mixture containing five milligrammes of hyoscyamia in 125 grammes of fluid. The next day the vomiting ceased, did not recur, and the patient went on favourably to the natural term of her pregnancy. A second case of the same kind was cured by the same remedy. Although hyoscyamia appears to have been successful in the treatment of these two cases, its efficacy as a certain remedy for the vomiting of pregnancy is not by any means established. It is well that the drug should be used, that its true value may be estimated, but as the vomiting is due to what may be called natural causes, permanent relief can scarcely be expected to be obtained by the use of a drug.

Royal College of Surgeons of England.

At the meeting of the Council on Thursday last, Dr. Sieveking was appointed Examiner in Medicine. With regard to the admission of women to the examination for the degree of L.M., it was agreed that Mesdames Jex Blake, Thorne, and Peachey should be informed that the members of the Board of Examiners in Midwifery having resigned their offices, the Council are obliged to postpone the holding of examinations for certificates of qualification in midwifery.

It appears that Dr. Graily Hewitt has withdrawn his name as a candidate for the vacant Examinership in Midwifery, and the Council are not inclined to offer the appointment to the younger class of obstetricians.

The Council, finding that the number of Fellows is yearly growing less, or in other words, that the number who take the fellowship by examination is insufficient to maintain the numerical strength of the present body of Fellows, has determined upon altering that examination in such a manner that it shall in future be less difficult for a member of the College engaged in practice to prepare himself for and to pass the examination for the fellowship. They have therefore made the following alterations:—

1. That subject to the following regulations, any member of the College be admissible to examination for the fellowship.

2. That there be separate and different examinations for members of less than ten years' standing, and for members of not less than ten years' standing.

3. That each of these examinations be in two parts, named respectively the first and the second part of the examination.

4. That members of the College of less than ten years' standing be entitled to be admitted to the first part of the examination at any time after receiving the diploma of member, and to the second part of the examination at any time, after having passed the first part, on producing satisfactory evidence of having attained the age of twenty-five years, and on having been engaged not less than six years in the study or study and practice of their profession.

Note.—Members of the College holding appointments in her Majesty's service, who have passed the first part of the examination, shall be admissible, on a special vote of the Council, to the second part of the examination at any time on producing satisfactory evidence of having been engaged not less than six years in the study (or study and practice) of their profession.

5. That for members of the College of less than ten years' standing the subjects of the first part of the examination be anatomy and physiology and the elements of comparative anatomy and physiology; and that the subject of the second part of the examination be surgery.

6. That members of the College of not less than ten years' standing be admissible to the first and second parts of their examination at the same time, or to the second part at any time after passing the first.

7. That the subject of the first part of the examination for members of the College of not less than ten years' standing be surgical and regional anatomy, and that the subject of the second part of the examination be surgery.

Note.—For candidates who are members of less than ten years' standing the second part of the examination will include surgical anatomy and pathology; for those of not less than ten years' standing the second part of the examination will be chiefly in practical surgery.

The present regulations will be retained (see page 79 of Calendar) in regard to admission to the first part of the professional examination of candidates who, not being members, shall pass the preliminary examination for the fellowship; but in such preliminary examination candidates shall be required to pass in all the compulsory subjects, and in not less than four of the optional subjects required for the membership of the College (see pages 71 and 72 of Calendar); and in addition to translate into English a passage from some Latin author not specially mentioned.

Medical Ovation at Hanover.

The fiftieth anniversary of Stromeyer's professional career—his wedding to science—was celebrated at Hanover on the 6th inst., and rarely, if ever, has any surgeon been the recipient of such distinguished ovations as were offered him on the occasion.

For days before the eventful one, each train which arrived at Hanover brought some of the *élite* of the medical profession from some part of Germany. On the eve of the day several hundred people assembled before his (Stromeyer's) house to sing and repeat eulogies in his honour.

Early on the morning of the 6th he received an autograph letter from the Empress of Germany, accompanied with a magnificent vase. The Order of the Red Eagle was presented him by Prince Albrecht from the Emperor. Telegrams from all directions, even from China, arrived, carrying congratulations; and deputations from the

various universities of Germany and from England presented addresses.

At five o'clock an excellent dinner was provided; three hundred covers were laid. Stromeyer was supported on his right by the Governor of Hanover, and on his left by the President of the German Parliament. Immediately after the soup, as is customary in Germany, the toasts commenced—"The Emperor," "Stromeyer," &c. "The Foreign Deputies" were given. Dr. Little returned thanks for the last, and replied very gracefully to the compliment which had been paid to the profession in England. Subsequently Mr. M'Cormac's health was proposed by Professor Thiersch, of Leipsic; he referred to his association with him in the Franco-German war; to Mr. M'Cormac's narration of events there, which had been translated into German; and to the uniform admiration and esteem in which he was held by the profession in Germany. Mr. M'Cormac was most happy in returning thanks, which he did in German, and which elicited repeated manifestations of applause. The "Military Surgeons of England" was next proposed by Surgeon-Major Schäfer, of the German Army, and responded to by Mr. Clarke.

The company included so many distinguished men that it seems invidious to name any in particular. However, one may name the Professors Bonn of Gottingen, Esmarch, Heine, Busch, Gerlach, Berthold, Czerny, &c., and the celebrated German poet, Herr Bodenstidt, so well known in this country as a translator of Shakespeare and of the poems of Mirza Hafiz, and equally distinguished for his accomplishments and courtesy, and who recited a very beautiful poem which he composed for the occasion.

Arsenical Wall Papers.

Dr. Hodges, of Belfast, reports that having submitted to chemical examination twenty-one specimens of room-papers, he found fourteen of them to contain arsenic in large quantities.

Milk of Sulphur.

At the Greenwich Police Court a chemist was charged with selling adulterated precipitated sulphur. The officer stated that he asked for two ounces of precipitated sulphur, for which he paid 3d. The analyst's certificate was produced, showing that the article sold contained 45 per cent. of sulphate of lime. A fine of 5s. and 2s. costs imposed.

We presume that this prosecution was successful because the article was sold as "precipitated sulphur," and that if "milk of sulphur" had been asked for the plaster of Paris compound might have been sold with impunity. This is a distinction without a difference—the fraud being quite as great in one case as in the other.

A Surprise in Store.

Under the above jocular heading the *World* reports a vague story of a man travelling in a Bayswater omnibus in charge of a parcel of dynamite containing a latent force "sufficient to tumble down half London." For a time the man jealously guarded his brown paper parcel, but falling into a state of "mental abstraction," he thought no more of his charge until arriving at his journey's end, when he found that it had been appropriated by a fellow-traveller. To add to this *excellent* joke the parcel is described as resembling a number of rolls of silver, and of course the disappointment of the thief is anticipated on finding only a number of rolls of a clayey substance. The *World* adds that we are not likely to have any information volunteered as to whether the thief threw the parcel aside in disgust, or whether it still remains on his domestic premises until some one shall throw it upon the fire. If there is no truth in the story, it is a misfortune that it should have been published; but if the *World* can rely upon the statement of the criminal who made such a confession, it is to be regretted that his name and gross negligence were not at once reported to the police, that steps might be taken to prevent the fearful calamity which will probably arise should this dangerous compound, even in small quantity, have found its way into the hands of one who is ignorant of its nature.

The Royal Society.

The following are the names of the fifteen candidates for the Fellowship selected by the Council to be recommended to the Society for election. The day fixed for the election is June 1:—Captain Abney, H. E. Armstrong, Rev. W. B. Clarke, J. Croll, E. Dunkin, Professor Erichsen, Dr. Ferrier, Colonel Lane Fox, A. H. Garrod, R. B. Hayward, C. Meldrum, E. J. Reed, Professor Rutherford, R. Swinhoe, and Professor Thorpe.

University College of Wales.

A meeting of the Council of this College was held at the Westminster Palace Hotel on Thursday last. There were present—Lord Aberdare, the President; Mr. David Davies, M.P., Mr. Henry Richard, M.P., Mr. Henry Robertson, M.P., Rev. Canon Griffiths, Neath; Captain Verney, R.N., Professor Hughes, Trinity College, Cambridge; Mr. Henry Parnall, Rev. Robert Jones, Mr. A. C. Humphreys, Mr. Stephen Evans, Mr. J. F. Roberts, Mr. Lewis Angell, Mr. T. J. Thomas, Rev. T. C. Edwards, Principal; Mr. Hugh Owen, Hon. Secretary, &c. It was announced by the Hon. Secretary that the amount received up to the present time from the collections made throughout Wales in the last weeks of October on behalf of a temporary sustentation fund exceeded £3,000. The Council, who are engaged in raising an endowment fund of £50,000 towards the permanent maintenance of the College, have appealed to the people of Wales to raise by collections in the last weeks of October in each year a sum of £2,000 a year for three years, as a temporary sustentation fund pending the completion of the endowment fund. The first year's collections have realised upwards of £3,000, and to this amount more than 40,000 persons of the middle and working classes have contributed. The endowment fund is sought to be made up by the contributions of the wealthier classes among the Welsh people.

Pedestrianism.

Last week Mr. Weston, the American pedestrian, effected at the Pomona Gardens, Manchester, the wonderful task of covering 111 miles in twenty-four consecutive hours. We are, however, now so accustomed to the astonishing walking exploits accomplished by Mr. Weston,

that they are no longer a matter of surprise. But on the occasion referred to he was accompanied in his walk by a man of the name of Parry, who bids fair to become a rival. Parry is a working mason, and has had only a week's training. At the end of the twenty-fourth hour, when Weston had completed his 111th mile, Parry had reached his 97th. He had taken three rests, amounting altogether to about two hours, and has certainly proved the *gamest* competitor yet pitted against the extraordinary American pedestrian.

Memorial to the late Dr. Parkes.

A MEETING, at which many of the members of the staff of University College Hospital and others were present, has been held at the residence of Mr. Erichsen, the object being to found a memorial to the late Dr. Parkes. Resolutions were agreed to that the memorial in question should be of a character to aid scientific investigation and practical study in the subjects to which Dr. Parkes' work had been especially directed, and that a subscription fund should be at once opened for the purpose.

The Exhibition of Scientific Apparatus.

A MEETING of chairmen of sections for organising the conferences in connection with the approaching Loan Collection of Scientific Apparatus at South Kensington was held on Monday. The following gentlemen were present :—Dr. Burdon Sanderson, F.R.S. (in the chair), Mr. Warren De La Rue, D.C.L., F.R.S., Professor Frankland, D.C.L., F.R.S., Professor Ramsay, LL.D., F.R.S., and Dr. Siemens, F.R.S. It was resolved that the conferences should be held on the following dates :—Physics (including astronomy) 16th, 19th, and 24th May ; mechanics (including pure and applied mathematics and measurement), 17th, 22nd, and 25th May ; chemistry, 18th and 23rd May ; biology, 26th and 29th May ; physical geography, geology, mineralogy, and meteorology, 30th May, 1st and 2nd June. It is proposed that addresses should be delivered on special subjects, and that the more important instruments exhibited should be described and discussed.

SEVERAL milkvendors were fined in various sums at the Clerkenwell Police Court for selling milk which, on being analysed, was discovered to be largely adulterated with water.

MR. WARD HUNT, has, on the recommendation of the Medical Director-General of the Navy, promoted Fleet-Surgeon M'Shane to the rank of Deputy Inspector-General of Hospitals and Fleets. Dr. M'Shane has not only the reputation of being an excellent officer, but is actually the senior of his class competent to be promoted.

IT has been notified by the Admiralty that they have appointed Dr. D. L. Morgan, C.B., M.D., Deputy Inspector General of Hospitals and Fleets at Hongkong, to succeed Dr. Pottinger as chief officer of the various naval medical establishments at Chatham, Dr. Pottinger having been promoted to the rank of Inspector-General of Hospitals and Fleets.

A CONSIDERABLE number of soldiers having recently been discharged from the army on account of physical disability after serving only a short time, the attention of medical officers is directed in a War Office Circular to the necessity for their exercising great caution in the examination of recruits, both as to their physical condition and their mental capacity.

A RIVAL of Tom Thumb is said to have appeared in Binghamton, New York, in the person of a boy five years old, who weighs nine pounds when fully dressed, is twenty-three inches in height, is physically perfect and healthy, and who talks very distinctly. The child weighed but two and a-half pounds at birth, and has not grown since he was a few months old.

THE combined annual meeting of the Italian Medical Association and of district medical officers (*medici condotti*) in Italy is to be held in Turin on September 18th to 22nd. It will be divided into three sections :—1. Medicine (including as sub-sections), Physiology, Mental Diseases, and Diseases of Children ; 2. Surgery (including, Obstetrics and Gynæcology, Ophthalmic Surgery, and Syphilography ; 3. Hygiene and Public Medicine.

THE Great Northern Hospital has received a Bank of England note for £500 anonymously. The City of London Hospital for Diseases of the Chest, Victoria Park, has received a bank note for £500 anonymously. The Goldsmiths' Company have given £200 to the building fund of the Great Northern Hospital. Lord Farnham has given £2000 and the late Miss Batt £2000 towards the building fund of the Adelaide Hospital, Dublin.

THE International Congress of Ophthalmology will meet in New York, on Tuesday, September 12. Delegates from Great Britain and Ireland and the Continent are requested to regisler their names at Chickering Hall, Fifth Avenue, on or before Monday, September 11. Those proposing to read papers will confer a great favour by sending the titles of their papers before July 1 to the secretary, Dr. John Roosa.

THOSE unpleasantly candid persons, the analysts, would deny even the inoffensive—if not very energetic—Indian subaltern the consolation of his "peg," and would shed a cloud of suspicion over the "tiffin," which would seem to be the engrossing employment of Oriental military life.

A quantity of aerated water was recently sent from Bombay to London to be analysed by Professor Wanklyn, Vice-President of the Society of Public Analysts. The result of the analysis is given in a report just issued, from which it would appear that out of ten samples forwarded only two were "fairly pure," and as many as five were calculated to induce diarrhœa in those who are in the habit of drinking them constantly.

Literature.

CYCLOPÆDIA OF PRACTICAL MEDICINE. (a)

This volume appears out of order, because the translations of Vol. IV. have been unavoidably detained in Germany. The articles are the work of four Continental physicians, whose biographies are briefly given in the preface.

Croupous Pneumonia, by Professor Juergensen, of Tübingen, begins the book. After giving extracts from Aretæus and other old physicians on the subject of chest inflammations, the writer goes on to demolish some received ideas as to the etiology of the disease. Statistics from several different parts of the world go to show that those who follow outdoor occupations are less liable to pneumonia than indoor workers. Persons in the prime of life, and of robust constitution, are less liable than the aged, the young, and invalids, and the disease is seldom really caused by a chill.

As to the influence of inhaling irritating mineral dusts, carpenters suffer more than masons, coal *merchants* more than coal *miners*. In comparing annual ranges of the mortality from different sets of diseases, it is found that the pneumonia years correspond more nearly with the years of high death-rates from respiratory diseases than with those of high death-rate from inflammatory diseases. The closest correspondence, however, is with the typhus years.

Under the head of *Pathology* the author gives a graphic account of the course of ordinary pneumonia, then an outline of the morbid anatomy, including an inquiry as to the source of the constituents of the exudation. The red corpuscles of course come from the blood. Cohnheim says that the pus cells have the same source. Buhl denies this, and regards the epithelium of the alveoli as producing the pus cells by a "sort of fissure process." The fibrin is derived from the blood, which is chemically altered by the morbid state, which probably changes also the walls of the vessels (Cohnheim). The same observer says that "in the beginning of every acute inflammation, so long as the number of the pus cells mixed with the transuded fluid is not considerable, the extravasated red corpuscles will appear more conspicuous than the white ones. On the other hand, the longer the inflammation lasts, the greater will be the excess of the colourless pus corpuscles, and the more will the colour change into grey or yellow."

Subsequently the exudation separates itself from the alveolar wall, and forming a soft granular mass, is gradually removed by expectoration, or chiefly by absorption, the structure of the lungs and the blood-vessels remaining intact. If the blood-vessels are obstructed, gangrene or abscess results.

The author is of opinion that caseation may occur as a result of croupous pneumonia.

Reckoning the attack from the rigor, the disease ends (in two-thirds of the cases) from the fifth to the eighth day. The temperature generally ascends to 104° or 105°. (Here let us thank the translators for having done the temperature sums for the reader.) The fever is of a manageable character—that is to say, it yields to cold baths and quinine, and the defervescence is rapid, falling in a few hours (usually about sixteen) to the normal; sometimes it falls below the normal, and continues daily the proper curve, but a degree or so below the ordinary curve of health.

The character of the pulse is to be studied more carefully than the frequency. Dicrotism is often present. The dilatation of the right side of the heart diagnosed by Piorry and others is not found after death, and is supposed by the author to be an erroneous inference from increased cardiac dulness, the lungs being imperfectly expanded.

Collapse, it is interesting to observe, may occur without there having been an unusually high temperature, though they may occur together.

Respiration as high as seventy-five per minute has been recorded by Grisolle. The change in the pulse-respiration ratio is attributed to the supposed excess of carbonic acid in the blood. The pulse-respiration ratio is often improved by the cold bath, as in a case where it was $\frac{1.7}{1}$ before the bath (temperature 77°, duration 38 minutes), and $\frac{3.8}{1}$ after the bath.

The signs are given under the heads of inspection, percussion, &c.; and with regard to getting at the patient, the author says: "In Holstein I have often had to rummage through thick feather bed cases to reach the patient, who was coiled up in a ball at the furthest side of a triple bedstead, clad in several woollen jackets to protect him from the cold."

Crepitant râles are audible not only in pneumonia, but in œdema of the lungs, in hypostatic congestion, sometimes (but rarely) in pleuritic exudation, and at the outset of capillary bronchitis.

As to the sputum, the author considers the presence of minute greyish-white casts of the finer bronchial tubes, as being characteristic, and states that he has seen sputum in other respects resembling that of pneumonia, in miliary tuberculosis of the lungs.

A patient twenty-five years of age was carefully watched by Riesell and Huppert, who calculated the daily ingestion and loss of nitrogen (in the urine, fæces, and sputum) during twenty-eight days of pneumonia. The general result obtained was that the body had lost in weight about six per cent., while the loss of nitrogen was from twenty to twenty-five per cent. during the period of illness.

Cerebral symptoms often accompany a high temperature. They are most commonly seen when the disease affects the upper lobe. Childhood, alcoholism, anæmia (as from venesection), excitable disposition, and special brain disease, all favour their development.

Of complications, pleurisy with effusion occurs in about five per cent. of all cases in the Continental hospitals. An accurate determination of this complaint requires repeated careful examination of the chest. The usual experience that capillary bronchitis, emphysema, and heart affections considerably increase the gravity of the disease is here endorsed. Pericarditis occurs in about four per cent. of cases at Basle (a high proportion); at the same place it is found that jaundice supervenes on pneumonia in from five to twenty-eight per cent. The mortality from this complication varies; its bad effects are attributed to the influence of the biliary acids on the blood and heart. This is the author's view of the so-called "bilious pneumonia," which he denies to be a separate affection.

Drunkards suffer from two forms of the disease, which have been accurately defined by Huss—the delirious and the adynamic; the latter, occurring in those who are very cachectic, is the most fatal variety.

Juergensen says: "Croupous pneumonia belongs to the group of infectious diseases," and gives his reasons at length for this statement. In this, as in other cases, the reader is led to coincide in the writer's views by the force and confidence with which he gives his opinion, and the careful process of reasoning by which it is supported.

Regarded as above, as an infectious disease, "Nature cures, and the only duty of the physician is to maintain life till this cure is effected." "The moment the 'Magister' is willing to give up the place he imagined he was able to occupy to the 'Minister Naturæ,' our treatment will be more successful than it is now."

Is the medical man to fold his hands, then, by the side of a pneumonic patient? By no means. Baths at a tem-

(a) Cyclopædia of Practical Medicine. Edited by Dr. H. von Ziemssen. Vol. V. Diseases of the Respiratory Organs. English Translation, by Dr. Yeo, London, Drs. Ball, Delafield, &c., of New York. Edited by Dr. Buck, of New York. London: Sampson Low, Marston, Low, and Searle. 1875.

perature which makes one shiver are to be used in the febrile stage. The fear of "taking cold" is spoken of as "this ghost which has been restlessly wandering about for centuries past."

And when venesection at a certain stage of the disease is under discussion, the author considers that it should "be left out of the text-books—as it serves as a welcome salve to the conscience of the weak man whom Fate makes a physician as a punishment to his fellows."

Quinine is given in very large doses—as much as seventy-five grains is mentioned. The reader is referred to the work for the circumstances under which it is thus used: "Such domestic remedies as black stockings, or covering the feet with lamp-black, as a substitute for the general bath, as recommended by Paul Niemeyer, the quinine hater, I have never tried."

Thus we are not left to wander among a host of remedies and choose at will; but the course of treatment is given clearly and decisively.

Catarrhal Pneumonia, broncho-pneumonia, or lobular pneumonia is "apt to occur after the infectious diseases, as measles, whooping-cough, diphtheria, &c."

As an example of the graphic description of symptoms found in this book, let us give the aspect in acute catarrhal pneumonia: "Rapid superficial respiration, with playing of the nostrils, and slight moaning, the face reddened and cyanotic, the eyes glistening, &c."

The progress of the disease is much more irregular than that of the croupous form, the temperature rarely rising so high as in the latter disease.

As to the signs, it is encouraging to be told that "the physical diagnosis of an acute and not very extensive catarrhal pneumonia is a most difficult task."

Having given the points to be noticed in order to distinguish the form of disease, the author begins the treatment by showing that the respiration is much embarrassed; the air of the room must therefore be warm and moist. With this exception the catarrhal is to be treated like the croupous variety of pneumonia.

Ziemssen once reported a case in which a child had been killed *secundum artem* by bleeding.

After a short chapter on *Hypostatic Processes*, the author treats of *Pulmonary Embolism*, or *Pulmonary Apoplexy*.

The emboli are of two classes, the *mechanical*, mere plugs, and the *specific*, which may be designated as *infectious*; "the former produce hæmorrhagic infarctions;" the latter "result in embolic or metastatic abscesses." Diagnosis obscure, prognosis "bad," treatment "to strengthen the heart."

Professor Hertz, of Amsterdam, contributes articles on several subjects.

Œdema of the lungs is described as "resulting sometimes from congestio n, and results in speedy death." Sometimes it is the result of a dropsical crasis, then running a chronic course. "An acute œdema may, though not frequently, take place in the course of an acute nephritis." *Anæmia* and *hyperæmia* are treated in the same chapter.

Papers on *Hæmoptysis* and *Atelectasis* are followed by one on *Atrophy* and *Hypertrophy* of the lungs, from which we quote: "Atrophy is a lesion of old age, and must be considered as the result of imperfect nutrition." "On opening the thorax the lungs are seen as small organs, sometimes quite shrivelled up and diminished by one-third or more of their volume. The atrophy is most marked in the superior lobes, especially the apices and anterior borders." On section, "the tissue is relaxed, and of a coarse cellular structure, and whenever a number of adjoining air cells have, by the wasting of their septa, coalesced, it resembles a network with large meshes."

The article on hypertrophy of the lungs ends with the conclusion that hypertrophy of the lungs does not exist!—the enlargement of one lung when the other is destroyed or incapacitated being really due to emphysema.

The subject of the causation of *pulmonary emphysema* is very fully considered, and one view attributes the disease occasionally to an affection of the chest walls, the change in the costal cartilages being thus described by Freund: "Fibrils assume a dirty yellow colour, and become softened, and coarse fibroid. These fibres tend to bind and twist round spaces forming between them. The cartilage is thus pressed apart (in the outer layers), the tissue loses its flexibility and becomes brittle." The result is that the ribs are pressed farther apart and upwards, and "the thorax, as regards the six lower true ribs, assumes permanently the attitude of inspiration."

The immunity from phthisis which emphysema was supposed to confer does not appear to be as generally believed in as some years since. The two affections coexist in some lungs, the expansion of the alveoli being vicarious.

In indicating the treatment, the benefits of compressed air are said to be—"(1) That the air pressure heightened by 1¼ to 1½ atmospheres, promotes the expiratory design of the elasticity of the thorax and of the intestinal gases. (2) By increased pressure on the vessels without the thorax the return of venous blood is facilitated, and by an analogous action upon the mucous membranes the catarrhal hyperæmia of the bronchi is lessened. (3) That by the relatively high oxygenation of the air entering the lungs the *besoin de respirer* felt by the patient is mitigated." The editor has here added a full and clear account of Waldenburg's apparatus, by which air can be rarefied or condensed to an exact fraction of an atmosphere.

The sputum in *gangrene of the lung* is thus described:

"Three separate layers may be recognised, the uppermost curved, with a layer of thick froth, is yellowish-green, and consists of grey or green purulent mucus. The middle layer is white, contains a quantity of albumen, is serous in consistence, and is traversed with floating shreds of mucus. The lowest stratum presents a purulent sediment, green, yellowish, or brownish; in it lie soft yellow stinking lumps, and many blackish flakes, probably shreds of lung tissue." Then follows the chemical and microscopical examination of the sputum.

Oil of turpentine in spray, or vaporised by heat, and thus inhaled, is found by Hertz to constitute the best remedy for pulmonary gangrene. Quinine in ordinary doses is also to be given.

New growths in the lungs, and in the *mediastinum* (let us call attention to an interesting series of short notes of dermoid cysts), and *parasites in the lungs*, are the concluding subjects of Professor Hertz's part of the volume. His treatment generally approaches to that of most English physicians.

Professor Ruehle, of Bonn, contributes an excellently written and interesting paper on *Phthisis*.

He has made a trifling contradiction in stating (p. 488) that "persons poorly fed are not specially liable to consumption." And then (p. 492) that "food of poor quality promotes the occurrence of phthisis." And in the same page, "the poorness in the quality of the food exerts an influence upon the production of consumption."

A sketch of an ordinary case, and the signs and symptoms of the disease, are very well given.

In speaking of hæmoptysis, the writer says that it is rarely dangerous to life—"in the later stages it may be comparatively unimportant," which is contrary to general experience, we think, in England at any rate.

In allusion to the patient's erroneous ideas about his complaint, it is said: "A colleague made the striking remark to me lately that he had met with few consumptives who within a few weeks of their death had not ordered new shirts to be made."

While some striking charts show typical fever curves, from ordinary tuberculous fever, and from hectic, Hertz says that "the fever of phthisis presents all possible variations, even in the same individual." "The course of the fever will naturally be considerably modified by the occurrence of complications."

Amyloid degeneration of the abdominal organs has been said to take the place of pulmonary tuberculosis, but the writer takes the contrary view. The affection attacks the

liver, spleen, kidneys, and intestinal mucous membrane; "its presence is indicated by pallor and œdema of the skin, painless enlargement of liver and spleen, &c."

The treatment of phthisis occupies small space, nearly all of which is taken up with prevention, dietetic and climatic measures. We hope that it is not true in England that "our modern life removes the physician more and more from the position of the family medical adviser and guide of the physical education," or that "medical practice is being converted into a trade."

Professor Ruehle ends a well-written contribution with a short chapter on Acute Miliary Tuberculosis, in which the diagnosis from enteric fever is fully given. Then follows—what will be considered by many the most valuable part of the book—Rindfleisch's article on *Chronic and Acute Tuberculosis*. The reader will here find a moderate exposition of the production of tubercle. "Tuberculosis in man depends in general on scrofula. Concerning the nature of scrofula we are still very ignorant." And further on he says: "Like certain animals, guinea-pigs, rabbits, and monkeys, scrofulous persons only need to have some local inflammation set up in order to become tubercular."

This chapter is illustrated by some finely drawn woodcuts, and the whole volume is clearly printed in large type, with good binding. It is a pleasure to meet with so scientific and interesting a work—representing as it does the most advanced opinions on chest diseases—and published in an attractive form.

VITAL MOTION AS A MODE OF PHYSICAL MOTION. (*a*)

When an author who has, like Dr. Radcliffe, earned by original research a high reputation, writes on the subject which has long occupied his studies, he deserves to be carefully listened to; hence this book is one which merits a careful perusal. Beginning with a historical sketch of the theories of vital action, he traces the lines of observation which have originated the idea that contraction is the normal state of muscle, and that volition acts by abolishing this state, upsetting the balance between antagonised muscles.

Dr. Radcliffe begins his experimental studies of the phenomena of motion by observations on undifferentiated protoplasm, which he shows to have no action on the electrometer other than that of the earth or unorganised matter. In living muscle he recognises, by the aid of Sir William Thomson's quadrant electrometer, currents which diminish as death overmasters life and disappear at the insetting of *rigor mortis*. He shows that the electricity of a cross section of the muscle differs from that of a muscular surface in kind as well as in degree, and he deduces from his observations the theory that the actual state of a living muscle is that of an electro-motive element, the electric condition being statical, the cell- and fibre-contents being negative, while the cell wall and sheaths are positive. Hence he regards the tensional phenomena registered by the electrometer as of more importance than the mere current phenomena detectible by the galvanometer, and he accounts for the currents of high tension produced at the moment of action or relaxation, as phenomena of charge and discharge. On contraction the *negative variation* which takes place is only a weakening, not a reversal, of the current. In nerve the electrical relations of section and surface are the same as in muscle.

As Dr. Burdon Sanderson has shown by experiment that there are changes in the electricity of the heart synchronous with its actions, our author infers that these changes affecting Rosenberger's ganglia are the cause of the rhythm; he also infers that the rhythmic action in respiration is due to a parallel series of electrical conditions in the medulla oblongata. In discussing the heart's action Dr. Radcliffe hints at the possibility of the relaxation of muscle being dynamic, a position which would require a great deal of evidence to substantiate, and which is certainly not borne out by the cuttlefish mantle, where the arrangements of fibres easily explain its rhythmic motions. Dr. Radcliffe's conjecture as to the motions of oscillatoria as instances of electro-motive action must also be looked upon with great suspicion, as the same structural Leyden jar-like conditions would obtain in many other allied filamentous algæ—Lyngbya, &c., for instance, and yet no motion occurs.

The author next directs his attention to the phenomena of electrotonus, and dissents from the view of Dubois Reymond, that the current is weakened in catelectrotonus on account of the contrary direction of the two currents, and that it is strengthened in anelectrotonus on account of the reverse conditions. His grounds of dissent are the production by himself and Matteucci of the same phenomena in dead tissue, and the occurrence of the movement after the cessation of the nerve current. By him these phenomena are reduced to conditions of charge or discharge of free electricity, the charge causing rest and expansion by repulsion, the discharge causing action. This principle he applies to *rigor mortis*, which he regards as the unrestricted operation of molecular attraction; the electrical charge of living muscle and nerve being lost.

As our author regards the oxygen in the arterial blood as the agent which keeps up those electro-motive conditions in nerve and muscle which are related to the production of rest, so he accounts for the convulsions produced by hæmorrhage, by strangulation, &c., as due to the want of this, not to the stimulating influence of the carbonic acid, as Brown-Séquard teaches.

Following up these researches on the mechanical nature of normal action and the place of elasticity in muscular contraction, Dr. Radcliffe in the second part of his book directs attention to the pathological aspect of vital motion. Analysing the vascular conditions present in epilepsy, he shows that the premonitory pallor described by Delasiauve, the sighing, the pulse, either tense, *apnœic*, or feeble, but consisting of a wave of venous, not of arterial blood, all show a state of deficiency of oxygen, the maintainer of the electro-motive charge condition. The same holds good for hysteria, chorea, and uræmic convulsions; they are all in cases of deficient vascular supply and deficient red corpuscles. This is also evidenced by the state of the nerve centres, which are usually anæmic in these cases, and by the fact that the opposite condition of congestion rarely causes convulsion, but instead, relaxation and lost consciousness.

The history of tetanus, of hydrophobia, and other spasmodic diseases, Dr. Radcliffe also finds largely associated with a depression of brain power, and an anæmic condition, an irritation the very opposite of inflammation, and as he regards it a failure in the electro-motive action in the olivary bodies and the tracts connected therewith. Similarly tremor and delirium tremens he cites as cases in point of muscular contractions dependent on anæmia.

Passing from the structures which have to do with motion to those which register sensations, Dr. Radcliffe applies here in the case of neuralgia and the preliminary pains of gout and small-pox his theoretic view that pain is the result of an anæmic, depressed state of blood supply and its concomitant electro-motive failure; but in this portion of his study he is perhaps less happy than in his earlier chapters, although he tells us enough to show the possible applicability of his theory to the difficult subject of the value and origin of pain.

On the whole this work is one which well deserves the most careful perusal, and for which the physiological world should be much indebted to Dr. Radcliffe, as it is an effort after a sound physical theory on which to explain the complex phenomena of the actions normal and perverted of animal bodies.

(*a*) "Vital Motion as a Mode of Physical Motion." By Charles Bland Radcliffe, M.D., &c. London: Macmillan and Co. 1876. Pp. 252.

ZOOLOGY FOR STUDENTS. (a)

This manual, which we have not had the opportunity of noticing before, is based upon lectures that have been delivered by the author at Westminster Hospital since the year 1869. It has already met with a very unfavourable reception, and, although its faults have been much exaggerated, we are sorry to be obliged to endorse some of the opinions that have been passed upon it. The author says that in the lectures above mentioned it was his chief object to impart to others the teaching which he "had received from the great masters of the science in England, in order that younger comparative anatomists . . . might be able to transmit to a future generation, in the days of a retrograde anatomy, somewhat of the traditions of Hunter and Owen." And he has "been careful to exclude all unproven facts, or problematical classifications." Now we contend that the principle on which these observations have been made, and on which the work has been constructed, is wholly wrong. It would be quite right for a pupil of a great teacher of metaphysics, or of moral philosophy, to confine himself strictly to the dicta of his master, to defend them, or even to endeavour to "transmit them to a future generation." But a very different course should be pursued when we deal with pure science. This is a department of human knowledge which is never at a standstill. Science is not, as Dr. Blake calls the anatomy of the present day, retrograde—it is progressive. New facts are continually cropping up to add to our store of information. What are "unproven facts" to-day may be, to-morrow, unquestioned truths; the classifications that may be now only "problematical" may hereafter be universally adopted. It is therefore wrong of a teacher or an author of a text-book to conceal from the student the more recent facts or opinions that have been authoritatively published on the science he treats of, however much they may be at variance with what he himself deems to be the truth. In a scientific manual we expect to find the latest views on the subject, as well as the latest facts; and had the author been guided by this principle his representation of modern zoology would have been more complete, while it would not have prevented him showing his predilection for the teaching of the venerable anatomist who has given his "*imprimatur*" to this handbook, and to whose great work on "Palæontology" Dr. Blake has been largely indebted. Although, however, we find fault with the principle which has been inculcated in the preface, we must admit that this fault does not detract from the value of the book so much as might be supposed. If science is progressive its progress is slow, and the zoological facts and views that have been published within the last fourteen years are neither so numerous nor so important as to make their intentional omission a serious matter in a work that professes to give only a general outline of the whole subject.

We must, moreover, allow that the materials at the author's command might have been not only more extended, but might have been worked up and digested into a much more homogeneous whole than we find to be the case. At the same time, the plagiarism of which the author has been accused is by no means so gross as has been represented. In a work of this kind it is very difficult to avoid the semblance of that fault. All descriptions of the different bodies with which naturalists have to deal must necessarily be much alike. The description given of a plant or of a botanical order by one author must of necessity resemble that given of the same plant or order by another author. If Prof. Owen, Buckland, Huxley, or any other naturalist were set to describe the anatomical characters of the Dinotherium or the Pterosauria, their descriptions would evidently be much the same. Because Dr. Blake says the pectoral members of the Pterosauria are adapted for flight, their vertebræ procœlian, their bones pneumatic, their head large, &c., it does not follow that he has copied from either Owen or any one else. The established facts of science are the common property of all, and where there is little room for originality of composition, there can be little room for actual plagiarism. There are, however, two defects to which we would draw attention, and one of which is a serious omission in a work of any kind. We allude to the absence of an index, and of any glossary of scientific terms. Without the former no book is perfect, and with regard to a glossary, a knowledge of the etymological signification of the names and terms used by naturalists is at all times a great aid to the student's memory, not only with respect to mere nomenclature, but often with respect to some essential character of the animal named.

But notwithstanding these remarks, we must admit that Dr. Blake's manual is not without its merits, and in conclusion we may say that, with the exception of the blemishes above adverted to, and which can be easily removed in a subsequent edition, we can at all events recommend the work as one in which the student will find a clear and concise outline of the main features and established facts of zoological science.

(a) "Zoology for Students: a Handbook." By C. Carter Blake, D.Sc. With a Preface by Richard Owen, C.B., F.R.S. London: Daldy, Isbister, and Co. 1875.

Suppurative Inflammation of the Pancreas, Jaundice from Retained Bile, and Diabetes Mellitus.

The following interesting case, ending in death, and followed by a post-mortem examination, the observations throughout being made by Dr. Frison, appeared in the *Union Médicale*, Jan. 15th, 1876.

The patient was a young man, aged 28, a resident in Cochin China. In June 1873, he noticed a jaundiced hue in the skin, unattended by any other symptom, except diminution of the appetite.

Shortly afterwards his strength failed, he felt pains in the right hypochondriac region, and in the shoulder of the corresponding side; these pains were shortly followed by swelling in the abdomen, scrotum, and feet. His appetite increased enormously, thirst became very troublesome, the amount of urine secreted was greatly augmented, so much so that the presence of sugar was suspected, tested for, and discovered. The jaundice became very marked. The patient was sent to France in the month of March, 1874. At that period the jaundice was intense, emaciation extreme, and the weakness considerable.

The abdomen was tumefied, prominent, and evidently contained liquid. The volume of the liver was much increased. The lower extremities were very œdematous. The urine contained a large quantity of sugar and biliary pigment. No fever or diarrhœa. The stools were greyish, clayey, and abundant.

After a slight improvement, he grew weaker and weaker every day. He suffered from complete loss of apetite. Fever declared itself upon the 5th of April. By the 10th of April, the weakness was extreme, the patient being scarcely able to speak. Death closed the scene upon the 12th.

In addition to the skeleton-like emaciation of the body, and the yellowish-brown discoloration of the skin, and of all the organs of the body, the following were the post-mortem appearances:—

The intestines were enormously distended with gas. The stomach was empty. The pancreas was enlarged to three times its normal volume, the head and body being hypertrophied, indurated, and infiltrated; the tail was hallowed out by a large abscess containing thickened pus.

The bile duct was enormously dilated. The liver was enlarged in all its dimensions, weighing 2,500 grammes, soft, and presenting an olive-green colour. When cut into, its substance presented a very dark green colour; the biliary canals were dilated, and in the thickness of the small lobe, there were three small abscesses as large as hazel-nuts. The microscopical examination showed no alteration in the cells. The lungs, spleen, and kidneys were almost healthy.

Dr. Frison, in his remarks upon this case, dwells upon the interest it possesses, from the fact of diabetes mellitus coexisting with the lesions described in the pancreas and liver; he believes these latter play a part in the genesis of saccharine urine.

He notes the fact that Frerichs discovered atrophy of the pancreas in nine cases of diabetes, and fatty degeneration in five.

The connection between atrophy of the pancreas and diabetes mellitus has been observed by others also.

M. Jaccoud did not attach any importance to these facts.

Dr. Frison draws attention to the fact in the preceding case that the hypertrophied pancreas, in compressing the bile duct, determined the retention of the bile in the liver, the dilatation of the biliary canals, the tumefaction of the gland, and finally the diabetes mellitus. The affection commenced with the hypertrophy of the pancreas, and the diabetes was not produced until, owing to the consequent lesion of the liver, there was stasis of the bile. The lesions of the pancreas did not produce the diabetes directly, but as a consequence of their effects upon the liver, in which they over-excited the glycogenetic function.

Ablation of the spleen induces increased activity on the part of the stomach and pancreas, to which, according to Schiff, is due the increased voracity of animals upon whom this operation has been performed.

Is it not, then, a fair inference to draw, that destruction of the function of the pancreas has a similar super-exciting influence upon the functions of the liver, including that of glycogenesis ?

Abscess of the Anus in Typhoid Fever.

CHALOT (*Montpellier Méd.*, 1875, No. 5, *Centralb. f. Chir*, 1876, No. 5) gives the case of a soldier, 23 years of age, suffering from a severe attack of typhoid fever, in the course of which an abscess made its appearance in the region of the rectum, which broke spontaneously, and resulted in a fistula. In giving the case, Chalot takes the opportunity to record the frequency of this complication of typhoid fever, and recommends the use of the elastic ligature.

NOTICES TO CORRESPONDENTS.

☞ CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

READING CASES.—Cloth board cases, gilt-lettered, containing 26 strings for holding each volume of the MEDICAL PRESS AND CIRCULAR, can now be had at either office of this Journal, price 2s. 6d. The postal regulations not allowing the Journal to be stitched, these cases will be found very useful to keep each weekly number intact, clean, and flat, after it has passed through the post.

ROYAL COLLEGE OF SURGEONS IN IRELAND.—The Court of Examiners held a meeting on Monday, the 3rd instant, and following days, when the undernamed gentlemen passed the first half of their examinations for the Letters Testimonial of the College:—St. George Ashe, John Beatty, Howard Blyth, Robert G. Buckby, Joseph William Cartles, George Robert D. Charleton, James Vincent Clinch, Charles Henry Coghlan, John Conry, Patrick John Collins, Ephraim M'Dowell Cosgrave, Hubert Kelly Costello, James Davidson, William Day, O'Connell John Delahoyde, William Delmege, Richard Dickworth, Alexander Dunne, Arthur Daniel O'Connell Finnegan, Francis Chas. Fisher, William Edward Fitzgerald, John William Henry Flanagan, Patrick Halion Fox, Thomas Kinley Hamilton, Denis Hogan, Andrew John Horne, Henry Stewart Jackson, William Kennedy, Joseph King, George Reginald Leeper, Allen Lyle, George Lyndon, William Brittain Mackey, Michael Francis Macnamara, Joseph Edward M'Cracken, Thomas M'George, James M'Munn, Bartholomew Madigan, Jonathan Hill Malone, Robert Joseph Martyn, Lourneo Pereira Marques, William Kildare Miley, Timothy O'Connell, John Patterson, Charles Hill Penny, Henry James Penny, William Harlo Phibbs, Thomas O'Dwyer Russell, William Rinton Spowart, Terence Sweeny, Andrew Colquhoun Thompson, Edmond Joseph Thunder, Charles Joseph Trimble, William Butler Walsh, and Thos. Edward John White.

DR. LAPPER presents his compliments to the editor, and begs to state that he was not a candidate for the Chair of Botany in the Ledwich School of Medicine, Peter Street

Laboratory of Royal College of Surgeons, Dublin,
April 12th, 1876.

HARVEIAN SOCIETY OF LONDON.—Mr. Knowsley Thornton will read "Some Notes on the Progress in the Diagnosis and Treatment of Ovarian Tumours" before this Society on Thursday evening at 8 o'clock.

COMMUNICATIONS, Enclosures, &c., have been received from—Sir Wm. Fergusson, Bart., London. Dr. Pavy, London. Dr. S. D. Gross, Philadelphia. Dr. W. H. Day, London. Mr. Wright, Leeds. Dr. F. VACANCIES.

The Middlesex Hospital.—Assistant-Physician. Honorary. Candidates must apply to the weekly Board. (See Advt.)

Royal College of Surgeons of Ireland.—Professorship of Anatomy. Election April 27th. (See Advt.)

Birmingham General Dispensary.—Resident Surgeon. Salary commencing at £130. Applications to the Secretary.

Londonderry District Lunatic Asylum.—Resident Medical Superintendent. For particulars see advertisement.

Dover Hospital.—House-Surgeon. Salary, £100. For particulars apply to the Secretary, 13 Castle Street, Dover.

Liverpool Royal Southern Hospital.—Third House Surgeon. Salary, £60, with board, &c. Testimonials, &c., to the Chairman of the Medical Board.

Liverpool Dispensaries.—Assistant House Surgeon. Salary commencing at £108. Applications to the Secretary, 34 Moorfields.

Hospital for Consumption, Brompton.—Medical Officer. Salary commencing at £200, with board and residence. Full particulars of the Secretary.

APPOINTMENTS.

BUTLER, P., L.R.C.S.I., L.K.Q.C.P.I., House-Surgeon to the Queen Adelaide Dispensary, Bethnal Green.

DAVIES, E. P., M.R.C.S.E., Surgeon to the Carmarthenshire Infirmary.

DIXON, J., M.D., L.R.C.P.L., M.R.C.S.E., Medical Officer of Health for the Parish of Bermondsey.

JACOB, E. H., M.A., M.B., House-Physician to the General Infirmary, Leeds.

OSBORNE, J. H., Jun., M.R.C.S.E., Assistant Resident Medical Officer to the Nottingham Dispensary.

PARSONS, W. A., L.R.C.P.Ed., M.R.C.S.E., Medical Officer to the Warwick Union Workhouse.

RENDALL W., M.R.C.S.E., L.S.A.L., Medical Officer for the Maiden-Newton District of the Dorchester Union.

SAUNOBY, R., M.B., M.R.C.S., Resident Registrar and Pathologist to the General Hospital, Birmingham.

STEPHENSON, S. S., L.R.C.P.Ed., L.R.C.S.Ed., Medical Officer, &c., for the Kilkeel Dispensary District of the Downpatrick Union, co. Down.

VERNON, W., M.R.C.S.E., L.R.C.P.Ed., Medical Officer for the Bardfield District of the Dunmow Union.

WILCOX, W., L.R.C.P.Ed., M.R.C.S.E., Medical Officer of Health for the North Walsham Urban Sanitary District.

WILDING, J. L., M.R.C.S.E., L.S.A.L., Resident House-Surgeon to the Whitehaven and West Cumberland Infirmary and Fever Hospital.

Birth.

PHIBBS.—On the 8th inst., at 59 Boundary Road, N.W., the wife of Robert Featherstone Phibbs, L.R.C.P., M.R.C.S., of a son.

Marriage.

IRVING—WATKINSON.—On the 5th inst., at Holy Trinity Church, Huddersfield, by the Rev. T. H. Sharpe, John Irving, M.B.C.M., to Fanny, eldest daughter of the late James Watkinson, Beechwood, Huddersfield.

Deaths.

BROADFOOT.—On the 30th March, at Whithorn, Wigtownshire, Robert Broadfoot, L.R.C.S.Ed., aged 81.

DONOVAN.—On the 27th March, at Lower Leeson Street, Dublin, Michael Donovan, Surgeon, aged 85.

FULLAGAR.—On the 31st March, at Leicester, Frank Fullagar, M.R.C.S.E., aged 64.

HIGGINBOTTOM.—On the 7th April, at St. Alban's Villas, Nottingham John Higginbottom, F.R.C.S.E., aged 87.

IRISH POOR-LAW INTELLIGENCE.

NENAGH BOARD OF GUARDIANS.

MARCH 23, 1876.

A LETTER from Dr. M'Mahon, Toomavara Dispensary District, applying for a fee of £2 2s. for his attendance at Nenagh Petty Sessions in the prosecution of parties under the Sanitary Act.

(Resolved) "That at the last Petty Sessions held in Nenagh the Sanitary Board had several summoned and convicted under the Sanitary Act, and it was necessary to have two medical officers of the Union, Drs. Cahalan, of Nenagh, and M'Mahon, of Toomavara, as witnesses, to secure convictions. The medical officers applied to the Court for an order (as in the case of prosecutions under the Vaccination Act) on the Sanitary Board for payment of a fee for their attendance, but were referred to the Board. The sanitary authority now wish to be informed whether the medical officers under the circumstances are entitled to a fee for such attendance, in addition to their salaries as sanitary officer. Local Government Board's reply, stating that sanitary officers are required to attend and assist in all such proceedings in which their attendance or assistance may be required by the executive sanitary officer, and the additional salaries are intended to cover their duties. The question of travelling expenses might be a matter for the consideration of the sanitary authority under special circumstances."

We have already stated that, to the best of our judgment, the rule made by the Local Government Board that sanitary officers must "attend and assist at all proceedings" is waste paper, inasmuch as it is not authorised by clause 10 of the Public Health Act, which defines the limits of the Local Government Board's authority to make rules.

The question as to their competency to make this rule, and, therefore, of the liability of the sanitary officer to obey it, is before counsel, and we hope shortly to publish his opinion and advice upon the subject. Meanwhile, it seems to us that the decision of the Local Government Board, as set forth in their letter to the Nenagh Guardians, is nonsensical and contradicts itself. Clause 2 of the "Executive Duties" in the Sanitary Order directs the sanitary officer to "attend and assist" at prosecutions. If he be bound to assist by his evidence he is also bound to attend, and if he be not entitled to payment for assisting he is surely not entitled to expense of attending. But the Local Government Board proposes to make the assistance a matter of duty and the attendance a matter of special remuneration, which, as long as they maintain the integrity of the rule, is obviously inconsistent.

THE CORONERS (DUBLIN) BILL.

THE Committee of Council of the Irish Medical Association has been actively employed in the effort to obtain the insertion in this Bill of the amendments necessary to secure to the medical profession something like justice, and to bring to an end the illegal and disreputable system of medical evidence which has existed in Dublin under the cognisance of the Corporation for so many years. A petition, which we published last week, was presented to the House of Commons by the Hon. David Plunket, and arrangements were made to have amendments proposed if the Bill had gone into Committee on Monday, the 3rd, as was expected. The Bill was postponed until the 24th of this month, when it will be committeed, and pending this stage of its progress, the Committee of Council is taking steps to communicate to the members of the House the nature of the abuses in the Coroners' system which now exist and the means proposed to remedy them. The framing of amendments is by no means an easy task, because—while their object is to obtain if possible in every case the evidence of the medical man who was with the deceased at the time of death—it is impossible to carry this object to its full extent.

The original law of inquests was that the last medical attendant of the deceased should be summoned, but this arrangement was obliged to be abandoned, because it made compulsory the attendance of consultants in large practice whose testimony was, in many cases, not indispensable, and who could not leave their avocations to attend an inquest except under the most urgent circumstances. The law was altered to its present state to meet this difficulty, and the coroner was authorised to call in the evidence of any medical practitioner "in actual practice at or near the place," which, as our readers are aware, is interpreted to mean any relative or chum of the coroner who may have nothing to do except earn occasional inquest fees. The amendments which the Committee of Council of the Association propose to this or any other Coroners Bill are not finally agreed upon, but we believe they are substantially as follows:—

The 32nd and 33rd section of an Act passed in the 9th and 10th year of her Majesty's reign, intituled "An Act to amend the Laws relating to the office of Coroner, and the Expenses of Inquests in Ireland," is, as regards its operation in the county of the city of Dublin, hereby repealed; and be it enacted that, whenever the deceased person on whose body an inquest is held shall have been attended by a registered medical practitioner at the time of death, or recently before it, either at his or her home or elsewhere, or in a public institution for the treatment of injury and disease, the coroner, except in the case of the inability of

said practitioner to attend by reason of mental or bodily iilness, or absence from the district over which the coroner has jurisdiction, shall address a requisition, in form set forth in the schedule of this Act, to such practitioner to attend and give medical evidence at said inquest ; but in case there shall have been no registered medical practitioner in attendance on the deceased person as aforesaid, then the coroner shall issue his summons to the medical officer of the dispensary district or sub-district in which the death occurred or in which the body was found, to attend and give medical evidence at said inquest.

The intention of this clause is that when the coroner receives information of a death and decides upon an inquest, he shall send his requisition to the medical practitioner in attendance at the death. The requisition would be as follows :—

REQUISITION TO MEDICAL PRACTITIONER TO ATTEND AND GIVE EVIDENCE.

To Dr..... .....
residing at.....

You are hereby requested to attend for the purpose of giving evidence at an Inquest on the body of..... lately residing at.....which Inquest will be held at.....on.....day next, the.....day of ... .187...at the hour of.....o'clock. Take notice also that in case you shall within twelve hours of the service of the requisition fail to inform me of your intention to attend said inquest I shall issue a summons to you or another medical practitioner to attend and give medical evidence at said Inquest.

Signed this... .....day of.....187...
.....Coroner.

To this requisition the reply of the practitioner would be attached—perforated for tearing off—in the following form :—

NOTICE OF MEDICAL PRACTITIONER OF INTENTION TO ATTEND TO GIVE MEDICAL EVIDENCE.

In compliance with your requisition I hereby give notice that I purpose attending, and if required, giving medical evievidence at the inen upon the body of..... ..

Signed..... .....
Registered Medical Practitioner.

To.....

The Coroner for ... . District.

In the ordinary course of events the coroner's messenger would bring back a reply as to the intention of the practitioner to attend, or it would be forwarded immediately by post by the practitioner to the coroner. Twelve hours would be allowed for the return of this requisition, and after the lapse of that time the coroner would have power to exercise his discretion as to enforcing the attendance by summons. In nine-tenths of the inquests the practitioner would attend voluntarily, or else his evidence might be done without ; but cases might obviously arise in which the testimony of the medical practitioner last in attendance would be essential, and the coroner must have power to enforce his presence if necessary. The clause to settle this part of the subject as proposed by the Committee of Council is as follows :—

2. If the medical practitioner who was in attendance on the deceased person at the time of death or recently before it shall omit to notify to the coroner within twelve hours of the service of the aforesaid requisition that he purposes attending to give medical evidence at the inquest, then the coroner, if he considers the evidence of said practitioner indispensable for the true finding of the cause of death, may issue his summons to compel the attendance of said practitioner ; but if he shall not consider said evidence indispensable, the coroner shall forthwith issue his summons for the same purpose to the medical officer of the dispensary district or sub-district in which the death occurred, or in which the dead body was found.

It will be observed that in the first proposed amendment it is provided that the last attendant shall be called in, even in the case of an hospital surgeon, who, by the 32nd clause of the Coroners Act, is excluded from all right to a fee for his evidence. We regard this exclusion as monstrous, and its presence in the Act of Parliament as a relic of the narrow-mindedness of past legislation ; and the Committee of Council of the Association proposes that in the case of an hospital patient, as well as any other, the evidence of the person most competent to testify shall be had. As a fact, that evidence never is obtained, because the hospital surgeon—being denied any remuneration—refuses to attend the inquest, and leaves the matter to the resident pupil, who is generally unqualified, and therefore—presumably—incompetent, and thus the jury has no reliable facts before it upon which it may decide a doubtful case. It is therefore proposed to remove the prohibition against the payment of fees to hospital surgeons, and thus to secure to the jury the best testimony, even in the case of hospital patients, whose causes of death seem to be considered of little interest by the present law.

As to the question of fees, the Committee of Council of the Association thinks it fair to adhere to the scale at present paid, except in the case of post-mortem examinations, which are obviously deserving of a higher fee. It is also considered unfair that a medical witness should pay—out of his guinea—car-hire, to the amount of, perhaps, five shillings, and travelling expenses are therefore inserted in the proposed amendment, which runs as follows :—

3. The 5th and 6th items in the schedule of the 9th and 10th Vict., cap. 37, are, as regards their operation in the county of the city of Dublin, hereby repealed ; and be it enacted that—

"The coroner shall pay to each registered medical practitioner who shall attend at the place of inquest, or at any adjournment thereof, on the requisition or summons of the said coroner, and for the purpose of giving medical evidence, a fee of one guinea for each day or part of a day on which said practitioner may be required to attend at said inquest, together with an allowance, for travelling expenses, of sixpence for each mile or part of a mile of distance from the residence of said practitioner to the place where the inquest is held ; and in case the coroner or the jury on said inquest shall order an examination of the body by dissection, a further fee of two guineas for such examination.

This clause is also framed to protect the medical man against the injustice to which he is now liable of being called to an inquest, kept there all day, and in the end, when it is discovered that his evidence can be dispensed with, sent home fee-less. It is therefore proposed that the fact of attending in readiness to give evidence shall entitle the medical man to his fee ; and that, if brought back day after day on adjournments, he shall be paid for each day. Finally, it is necessary to provide for the case in which a charge of neglect or of crime is brought against the medical practitioner last in attendance ; and therefore the last part of one of the repealed clauses is necessarily reinstated. It runs as follows :—

"If any person shall state upon oath before the coroner that in his or her belief the death of the deceased person

was caused partly or entirely by the improper or negligent treatment of any medical practitioner or other person, such medical practititioner or other person shall not be allowed to perform or assist at the post-mortem examination of the deceased."

These amendments seem to us to be practicable and reasonable, calculated to work well, to serve the desired purpose of laying the best evidence before the jury, and not unduly to aggrandise the medical profession. As such they will, we believe, recommend themselves to any man of judgment; and, though it is quite possible that the present Bill will go no further, and they will therefore be inevitably postponed until next legislation on the matter, it will be advantageous that the question shall receive public discussion.

EVIDENCE AT VACCINATION PROSECUTIONS.

DR. KISBY V. BOYLE P. L. GUARDIANS.

(From the *Roscommon Herald*)

THE plaintiff sued defendants for £1 1s. which he claimed for attending and giving evidence in prosecutions against defaulters under the Compulsory Vaccination Act, at Ballyfarnon petty sessions, of which district he is Poor-law medical officer. He obtained a certificate from the presiding magistrate (The MacDermot Roe) and afterwards applied to the guardians for payment, but was refused on the ground of "no expenses incurred." Dr. Kisby attended before the Board, and produced records of instances (previously published in the MEDICAL PRESS) in support of his claim. The guardians, however, persisted in their refusal, and a trial before the Barrister at Boyle quarter sessions was the result.

Mr. Burke (who appeared for plaintiff) relied upon the 25th and 26th Victoria, that Dr. Kisby was not bound to go into court without the fee demanded by him.

Mr. M'Donnell (for defendants) relied upon the 10th and 58th sections of the Public Health Act.

Section 80 appoints the medical officer of each dispensary district as sanitary officer at a salary fixed by the Board of Guardians (as Sanitary Authority.)

Section 58 provides that any such officer appointed by the guardians to enforce the provisions of the Vaccination Act in Ireland compels the medical officer to be vaccinator of his district.

Article 2 of the Executive Officer's duties provides that the sanitary officers are bound, on receiving instruction from the Executive Sanitary Officer, to attend and assist in proceedings under said Act.

His Worship decided that Dr. Kisby was entitled to the amount sued for, and that it was not necessary for him to procure a certificate in such cases.

A decree was given against the guardians for £1 1s. and 12s. 6d. expenses.

The Clerk informed the board that the Chairman of Quarter Sessions had decided in favour of Dr. Kisby's claim for £1 1s. for attending at the Petty Sessions of Ballyfarnon in the prosecution of defaulters under the Compulsory Vaccination Act.

The Clerk referred to the 10th and 58th sections of the Act. And remarked that the Barrister had decided that Dr. Kisby should be paid the amount sued for, and his (the Clerk's) opinion was that if Dr. Kisby be entitled to payment all the sanitary officers were entitled to payment under similar circumstances.

Captain John Irwin—It would be well to leave the matter over for a larger board.

Mr. Stuart—But that will not affect the case.

The board decided that no appeal be made in the matter.

It will be observed that the solicitor for the guardians either confounded the law of Vaccination with that of Public Health, or else was gravelled for lack of argument. The prosecution of defaulters in Vaccination is provided for by a special Act, and by special rules, and the regulations set forth in the sanitary order of the Local Government Board have no more to say to it than to the certifying of dangerous lunatics or any other of the extra-sanitary duties of the dispensary medical officers. The ruling of the Chairman is very important in one respect, for he has decided that the medical officer must be paid for his evidence as a matter of simple contract, even if he has not asked for any certificate from the magistrate.

Under all the circumstances we advise our constituents to attend at the prosecution of defaulters, without waiting for a subpœna, making sure before doing so to have an explicit requisition from the relieving officer, if possible, in writing. When they have given their evidence they should apply to the magistrates for a certificate pointing out to them their legal authority to grant such certificate under the 13th Section of the Vaccination Amendment Act (26th and 27th Victoria, cap. 52). The certificate might be in the following form:—

Vaccination Amendment (Ireland) Act.

We hereby certify that Dr. A. B., having attended before us on this day and given evidence in the cases of certain persans prosecuted uuder the provisions of the Vaccination Amendment (Ireland) Act, ought to be allowed the sum of £ s. d., which shall be pain to him for such attendance out of the Poor Rates, as part of the expenses incurred in such proceedings, in terms of the 13th section of said Act.

Signed.....

... .

Magistrates sitting at Petty Sessions.

Dated this day of , 187 .

The wording of this certificate conforms as closely as possible with the exact phraseology of the Act of Parliament, and, to avoid a technical objection, ought to be adhered to as closely as possible.

If the magistrates should decline to give the certificate, nevertheless, the medical officer should apply to the guardians for payment, producing the written requisition of the relieving officer, and putting forward the claim as for work and labour done at the request of the guardians. If payment be still refused, the demand may be enforced, according to the ruling in Dr. Kisby's case, by a process to the Quarter Sessions, but if the medical officer be indisposed to take this course, he may refuse to attend again without a subpœna, and, if regularly summoned, may refuse to give any expert evidence until his fees be arranged for.

We have offered these recommendations in order to secure to the Public Vaccinators of Ireland their established rights, which neither the boards of guardians nor the Local Government Board seem disposed to recognise, but we would earnestly advise them to aid heartily in carrying out the law of compulsory vaccination, for the benefit both of the public and of themselves—to offer every facility consistent with the preservation of their rights—not to make any difficulty about attending on the requisition of the relieving officer, but, nevertheless, to act with firmness for the benefit of their co-officers whenever their proper remuneration shall be refused.

Dr. Kisby's case makes manifect the advantage which the profession enjoys in having at its disposal an organisation like the Irish Medical Association, which can accept the trouble, expense, and responsibility of establishing on a firm legal basis the rights of medical men. The Council of the Association have taken a course in this matter which it would not be easy for any individual medical officer to adopt. They will, we believe, be always ready to assert the rights of any Poor-law medical officer when their doing so affords them an opportunity of affirming a useful principle or settling a point of law.

REPORT OF HEALTH OF DUBLIN AND SUBURBS FOR WEEK ENDING APRIL 8, 1876.

Total registered deaths in Dublin and suburbs * ... 210
Ten years average of same week 163

COLERAINE GUARDIANS.

MEDICINE CONTRACTS.

THE Chairman opened the several contracts for the supply of medicines for the workhouse and the several dispensary districts of the union, there being the unusual number of seven. The various tenders were submitted to five medical officers, who were unanimous in recommending the acceptance of the tender by Mr. Collins, *which was lowest of all, with the exception of that of Messrs. Leslie*, which was 5d. in £6 higher than that of the successful contractor, who has had the supply of medicines to the union for the last eight years.

It would, we suspect, be amusing an instructive if we were enabled to submit the prices of these medicines and their quality to a competent pharmaceutical examination. We do not for a moment challenge the opinion of the five medical officers who guarantee the quality and prices of the drug supply, nor have we the least knowledge to enable us to express an opinion on the subject. Our acquaintance with the Irish drug contract system and with the principle of selection of the lowest tender leads us to suspect that a comparison of the two lowest tenders with the acknowledged market prices of the best drugs would be worth the trouble.

YOUNG MOTHERS.—In August, 1866, we reported in the *Cincinnati Journal of Medicine*, the case of a girl living in Shelby county, Ind., who commenced menstruating at three years and a-half. In a communication in the *Cincinnati Medical News*, January, 1876, from a physician in Shelbyville, we learn that when thirteen years and eleven months old, this girl gave birth to a mature, healthy male child. A few days since we attended a married girl in confinement, who was just fifteen years old. The labour was very tedious, lasting forty-eight hours, and had to be terminated by forceps; the child, male, weighing upwards of ten pounds, and the mother, are both doing well.—*American Practitioner.*

ON TUBERCULOSIS IN CHILDREN AND THE CONDITIONS WHICH RESEMBLE IT.

By W. H. Day, M.D., M.R.C.P.Lond.,

Physician to the Samaritan Hospital for Women and Children.

(*Concluded from page* 319.)

Treatment.—In considering the question of treatment, and the arrest or absorption of tubercle, we must, in a measure, disregard the varied and special symptoms of the disease, and sustain and support the general strength. The nutritive functions being primarily at fault, demand the closest attention, and whatever conduces to their healthy performance, holds out the best means of controlling morbid action, and of averting the tendency to local congestion and exudation, for when these changes have occurred, then the molecules or granular matter of which the exudation consists are liable to lead to softening and disintegration.

As cases of tuberculosis differ like any other forms of consumptive disease, remedies of an opposite character are required. In some instances in children, the temperature of the body is high at an early stage of the illness, and the circulation is accelerated; there is thirst and derangement of the gastro-intestinal tract, and food is not digested, even if there is any remnant of appetite left. Antiphlogistic measures and cooling drinks to subdue this febrile excitement are absolutely required. We have seen how frequently bronchitis or pneumonia are associated with this condition, and when they are met with, salines and diaphoretics are required before supporting measures can be safely employed. If the cough is hard and tearing, and there is soreness and constriction of the chest, it is clear that a tonic and stimulating plan would aggravate the condition. When moist sounds in the chest have succeeded to dry rhonchus or tubular breathing, we may commence the system of treatment which modern practice has sanctioned, and give cod-liver oil and mild tonics during the day time. In the evening, when febrile symptoms are chiefly observed, citrate of potass and the alkaline carbonates will abate the excitement, and soon enable us to give quinine safely in small or large doses so as to check the febrile exacerbations. For children, I am in the habit of giving a grain of quinine in powder, half an hour before going to bed, and sponging the body lightly with tepid water, if hot and dry, or with cold water if the temperature is disposed to rise rapidly.

Cod-liver oil is the most effectual remedy of all others in the management of this disorder, and may be given when febrile excitement has not departed, and there are signs of advancing local change. Dr. Williams says, "Cod-liver oil, when taken into the system in sufficient quantities, and for a sufficient length of time, acts as a nutrient, not only adding to the fat of the body, but also promoting the healthy growth of the protoplasm and of the tissue cells, and in some way, as an alterative, counteracting the morbid tendency to the proliferation of the decaying cells of pus, tubercle, and kindred cacoplastic and aplastic matters." (*a*)

When the oil is pale and pure it seldom causes nausea or disturbs the function of the liver. I prefer giving it after a meal in a little orange wine, or with a small quantity of milk, which, however, does not always agree. Dr. Williams gives it with a mild acid or aromatic bitter—he gives the nitric, hydrochloric, sulphuric, or phosphoric according to the special circumstances of each case, and I can speak most favourably of the combination. I have long been in the habit of giving hydrochloric acid before the meal, and the oil afterwards. In weakness of the stomach, with a tendency to retching and nausea, the 1-24th or 1-32nd of a grain of strychnia is given by

(*a*) "Pulmonary Consumption." Longmans, Green and Co., 1871, p. 322.

Dr. Williams with each dose of oil. But it must have come within the experience of all that cod-liver oil, when long continued, is apt to disagree with the stomach, and to cause biliary derangement, particularly if the diet is not carefully regulated. Here it must be suspended for a time, and an alterative and alkaline treatment employed till the digestion is restored to a healthy state. In the winter season of the year, cod-liver oil is an indispensable remedy and may be continued for months together. There is a preparation called the compound phosphorated cod-liver oil, (*a*) which I have found of use in the strumous diseases of children. But, however combined, the daily use of the oil has superseded every remedy that has hitherto been proposed, and there is not a physician in this country or abroad, who is not convinced of its efficacy, either in prolonging life or curing the disease.

The hypophosphites of lime and soda with strychnia, iron, and quinine form an excellent combination with which I am satisfied in these cases of tuberculosis, and all states of general debility and nervous exhaustion.

Whilst we are giving astringents to check diarrhœa, and sedatives to relieve cough, we are diminishing the strength and appetite, in blind pursuit of the enemy, and the disease advances. The best means of relieving these symptoms is to increase the general strength, by supplying the system with fatty elements in a form that can be easily assimilated. We have found this remedy in cod-liver. The molecular fluid of the chyle consists of fatty particles, from which the blood and tissues of the body are formed, and if chylification is imperfect or tardy, the blood is watery and albuminous, and thus the step towards exudation is formed. Physiology never exposed a greater therapeutic error than when it showed the danger of treating low inflammatory exudation by depressing the vital powers so that its molecules were incapable of passing through those transformations which lead to growth and elimination. By an opposite mode of treatment, depraved nutrition is restored, the respiratory organs are stimulated to active exertion, and the tissues attract from a better quality of blood, the necessary elements for the support of the body.

In the case of an infant, if the mother is delicate or comes of a consumptive stock, and cannot suckle her child, a healthy nurse should be procured. Older children who exhibit a tendency to tuberculosis, should wear flannel next the skin; the diet should be plain and nutritious, consisting of eggs and milk, and meat twice a day if the child can digest it.

Quinine by improving the strength and appetite, and iron by altering the quality of the blood, are two most valuable remedies when the digestive functions have been brought into a proper state, and there is no risk of renewing inflammation in the pulmonary organs. If there is any degree of febrile excitement or cough, it is preferable to omit the iron till it is reduced, and direct the treatment to special symptoms. The effect of quinine in non-tuberculous cases is very remarkable in controlling the remissions and exacerbations of the fever: it is the most valuable remedy we possess, and in every case of oscillating temperature which I have treated, it has been followed by a fall. Where the fever has not so quickly yielded, the lung has shown evidence of some change in the shape of small and localised pneumonia, or gastro-hepatic disorder, or it has been suspicious of real tuberculosis. Cod-liver oil should always be given in the daytime when the temperature is normal, and quinine in the evening before the rise is expected. Of the benefits derived from change of air and sea bathing they are too obvious to need illustration.

(*a*) Prepared by Savory and Moore, New Bond Street. A fluid dram contains one grain of iodine, two grains of bromine, and the one-fortieth of a grain of phosphorus.

MEDIAN LITHOTOMY. (*a*)

By William Stokes, F.R.C.S.,
Professor of Surgery, Royal College of Surgeons, Surgeon to Richmond Surgical Hospital.

The fact that cases requiring the operation of lithotomy occur so rarely in Ireland ought, in my opinion, to make operating surgeons in this country devote a special attention to it, with a view of determining the method that is accomplished with most facility and at the same time is fraught with least peril to the patient. Many have held and still hold the opinion that median lithotomy fulfils these conditions, and to this procedure I wish to draw attention on the present occasion.

This operation, formerly termed the "Marian," was for a lengthened period consigned to perhaps an ill-deserved oblivion, until revived and improved upon by Manzoni, De Borsa, and Allarton. To the last-named surgeon undoubtedly belongs the credit of being the author of this *rénaissance* of the procedure in England.

It would be out of place on the present occasion to describe the steps of the operation known as Allarton's, as they are doubtless familiar to all present. I shall draw attention, therefore, only to some of the modifications and improvements of the operation that have been recently suggested. Sir H. Thompson, instead of plunging a straight double-edged pointed bistoury in the mesial line of the perinæum and half-an-inch in front of the anus, exposes the staff by cutting from before backwards. This, though it protracts the operation, is decidedly an improvement, for, as Mr. Porter has pointed out, if the perinæum be deep and the bistoury of an ordinary length, the blade of the instrument will not be of sufficient length to reach and open the urethra in the required situation. Accordingly he pushes Allarton's bistoury about a quarter of an inch in depth, with its back towards the bowel, half an inch anterior to the anus at the raphe, after which an incision an inch and a-half in length is made towards the root of the scrotum, in which the skin and superficial fascia are freely divided. This being done, the knife at its first starting place is plunged into the staff at the apex of the prostate, and drawn forwards to the extent of the superficial incision. Erichsen recommends a rectangular staff, considering that "the surgeon can judge of the exact point where to enter the knife (directing it so as to open the groove just below the angle), which he cannot do with the curved staff." He then passes a director along the groove, after making the incision, and, before removing the staff, effects digital dilatation. Now these modifications of the operation, though doubtless improvements on the original procedure, do not get rid of one of the main alleged disadvantages of the operation, which is, the limited space which it allows for the introduction of forceps, and the removal of calculi, even of moderate size.

I found that in the second of the cases in which I performed the operation, on introducing my finger into the bladder, I found it very tightly grasped, and that a great deal of very forcible dilatation would be necessary in order to introduce a forceps, and remove a stone one diameter of which was, as I ascertained by previous measurement, fully one inch. Having so great a dislike, and indeed dread, of forcible dilatation of the prostate, as I have of the very doubtful—but, I regret to say, at present fashionable—piece of French surgery imported into this country some years ago, which consists in forcibly tearing open a strictured urethra, I passed a lithotome along my finger and made a lateral incision in the prostate, which gave me ample room for the easy introduction of a large-sized forceps and the removal of the stone.

This modification has, I am aware, been suggested both by Allarton and Sir H. Thompson; but I am not aware that they ever put it into practice. I cannot but think

(*a*) Read before the Surgical Society of Ireland, April 7. The discussion will be found on page 339.

that in all cases where there would be any risk of prostate laceration it should be employed. In cases where the operation is performed for the removal of such foreign bodies as pieces of sealing-wax, portions of bougies, catheters, hair-pins, &c., this modification would of course be unnecessary.

The first case in which I performed the median operation was one which, as it has been already published, I shall not do more than briefly allude to. The patient, æt. 40, suffered from urethral stricture, and was in the habit of performing auto-catheterization. One day, while partially intoxicated, he passed the instrument, and left it in. The catheter, by an action which I do not think has as yet been clearly explained, passed into the bladder. I hoped to have been able to remove it by a lithotrite, but, owing to the existence of the stricture, failed to pass the instrument. Though the lithotrite could not be passed the lithotomy staff could, and I then performed median lithotomy, and the perinæum being very deep, I adopted Porter's modification, and successfully removed from the bladder an *entire* gum-elastic catheter. Believing the case to be a unique one, I wrote to Sir H. Thompson, and he observed in his reply: "It is curious I have never encountered a catheter to remove. I have always made up my mind to remove it by a lithotrite, if it did happen, if possible. I have removed a hair-pin easily by that means, which is a much more awkward foreign body. I have removed a part of a stick of sealing-wax, and like pin by the median operation. In your case, of course, the narrowing of the urethra would make the lithotrite impossible.

My second case was that of a patient, æt. 45, on whom I operated on the 27th of last November. The patient stated that for seven months and a-half previous to his admission, which was on the 17th September, he had been suffering intensely from all the usual symptoms of stone in the bladder. Dr. Shanley, of Athlone, detected the existence of calculus, and recommended the patient to my care. The patient, on his admission, was in a very emaciated, debilitated condition. His face was cadaverous and emaciated, his appetite bad, his pulse weak and compressible, slept badly at night, and suffered much from chronic diarrhœa, and pain which he referred to the perinæum, top of penis, bladder, and thighs. During micturition the water frequently stopped. Eight or ten times a night he experienced desire to micturate; and from all these circumstances I have mentioned his condition was truly pitiable.

On the 21st September I sounded the patient, and at once struck the stone. Having regard to the general condition of the patient, I was of opinion that operation at that time was inadmissible; and in this view I was supported by my colleagues, Drs. Thomson, Stoker, and Corley, who on several occasions saw the case in consultation with me. Mr. Fleming, Mr. Callender, of St. Bartholomew's Hospital, who was in Dublin at the time, and Mr. Porter, entirely concurred in the view I and my colleagues took as to the inadvisability of any operative interference at that time, and accordingly I directed my attention chiefly to arresting the chronic diarrhœa and the improvement of his health generally.

About the middle of November the patient's health was so much re-established that I determined to operate; and having regard to the fact that there was evidence of the existence of several calculi, and that the patient's feeble condition rendered it desirable that the operation should be attended with as little hæmorrhage as possible, I determined on performing median lithotomy. Ably assisted by my colleagues and Dr. Fleming, late surgeon to the hospital, I performed the operation, Dr. Corley holding the staff. Introducing the fore-finger of my left hand with its palmar aspect upwards into the rectum and feeling for the apex of the prostate, I cut down on the staff and freely opened the urethra at its membranous portion. I then introduced Allarton's ball-probe into the groove of the staff, and here an awkward hitch in the operation occurred, which gave me at the time considerable anxiety. On passing the probe along the groove of the staff a certain distance it refused to go any further, and thinking it must have arrived at the end of the staff, I withdrew the latter, and then, on passing my finger along the probe, I was disappointed at finding that it did not reach the bladder. The staff was then returned into the bladder, which manœuvre was performed by Mr. Fleming, and the probe was then successfully introduced. The staff was then withdrawn, and I inserted my finger along the probe into the bladder. The probe was then withdrawn, and finding that my finger was grasped with unexpected tightness at the neck of the bladder, and feeling sure that a great amount of forcible dilatation would be necessary to make the opening sufficiently large to introduce the forceps, seize and extract the stone, I modified the operation by enlarging the opening by incision instead of by forcible dilatation. I accordingly introduced a lithotome along my finger and incised the prostate, cutting downwards and a little outwards. This gave me ample room to complete the operation satisfactorily. The bladder I then carefully washed out, which was especially necessary, as the calculi being soft, broke down during the extraction, and left a great deal of *débris*, which could only be removed by careful washing. The *canule à chemise* was then inserted and the patient removed to his ward.

I shall not detail the daily progress of the case towards recovery, as there was nothing specially noteworthy in it. He slowly but steadily recovered, and on his discharge on the 13th January the wound was quite healed; he passed his water quite naturally, had lost all vesical irritability, and his health generally was much improved. (*a*)

My colleague, Prof. Cameron, examined the calculus, and reports that it consists mainly of the urates of calcium, ammonium, and sodium, and a little of the triple phosphates.

As regards the instruments, I think, at all events in operating on adults, it would be better to use a longer knife than the one recommended by Allarton. One similar to this instrument, which was specially made for a case Dr. Corley operated on, and to which I shall presently allude, would, I feel sure, be found preferable. I think also having the staff open at the end, similar to the one Mr. Dease I believe first recommended for lateral lithotomy, would be an advantage, as there would be no risk of the end of the probe catching on it and being hitched back, if I might so express myself, on the withdrawal of the staff. Lastly, I think the bulbous extremity of the probe should not be so globular. If it were flattened at the sides, somewhat similar to Teale's probe dilator, there would then be no risk of the probe getting fixed in the groove of the staff, as happened in the second of my cases.

The main advantages which have reasonably been claimed for the operation are, the small amount of section by the knife, facility in reaching the bladder, absence of hæmorrhage, and prompt cicatrization. As M. Mueler, of Beaucourt, has observed, "A method calculated to simplify an operation, and at the same time to avert the perils of hæmorrhage, is obviously preferable to any other; and in this respect median lithotomy is unquestionably far superior to all other systems of perineal section." The only artery of any importance that can be wounded is the artery of the bulb, and if it is divided it can easily be secured by torsion by the ligature.

Sir H. Thompson observes that, of the cutting operations for stone, the median "presents that in which the bladder is reached with the smallest amount of section by the knife." And it becomes dangerous in proportion to the amount of laceration, or our pressure under the name of dilatation, made use of.

The principal alleged disadvantage of the operation is a twofold one. First, that it is not applicable to cases

(*a*) For the above notes of this case I am indebted to Mr. Gordon, our able resident surgeon.

where the calculi are of large size ; and secondly, that there is greater danger of urinary infiltration than after the lateral operation. Mr. Cadge, of Norwich, from whom I recently had an interesting communication on this subject, observes : "Median lithotomy is very good for those cases where the stone is small." He has, however, I may mention, successfully removed a stone by the median section weighing five ounces. The patient, he informs me, "had hard work to recover," which, considering the great size of the stone, was hardly to be wondered at. In such a case I should say the lateral section of the prostate I have spoken of would be specially applicable, or the plan of crushing the stone through the wound in the perineum, as recommended by Dolbeau and Rizzoli, and recently practised by my friend Mr. O'Grady in a case in Mercer's Hospital.

By the adoption, therefore, of either of these proceedings, the first of the alleged disadvantages I have alluded to can be got rid of.

The second objection that has been urged is that there is greater danger of urinary infiltration after median than after lateral lithotomy. This has been stated to occur in consequence of an inevitable wound of the layer of pelvic fascia, which is given off from the opening in the triangular ligament which the membranous portion of the urethra pierces, and which, passing backwards over the membranous portion of the urethra not contained in the layers of the ligament, goes to form the capsule of the prostate gland. In reference to this point, I wish to draw attention to the observations of our able secretary, Mr. Richardson, in a communication on lithotomy, which he published in the MEDICAL PRESS AND CIRCULAR in 1865. He has clearly pointed out that this layer of fascia must be wounded in the lateral operation, and observes : "How, may it be asked, can the triangular ligament be divided, and posterior part of membranous and prostatic urethra be opened in lateral lithotomy without wounding the capsule? Impossible ; and therefore the mortality should be much higher than it is if the wounding of the capsule played the important part attributed to it as a cause of the fatal issue of lateral lithotomy."

These observations apply with equal if not greater force to median lithotomy. But I would ask, has any one here ever known a case in which median lithotomy was performed terminating fatally from urinary extravasation? I never have ; and I may add, I have never known of a case in which there was, after lateral lithotomy, a fatal issue from the same cause.

As regards the statistics of this operation, it cannot be denied that the results present, as regards mortality, a most favourable contrast to those obtained after any of the other operations for stone.

In Dublin, though the cases have been few, they have all, as far as I can determine, been successful. The late Mr. Smyly has published a remarkable case, in which he performed the operation twice successfully on the same patient. Mr. Porter's cases have been all successful. My colleague, Dr. Corley, has also published a remarkable case, in which there were special difficulties attending the operation, in consequence of the patient having suffered from chronic rheumatic arthritis of the right hip, which was in consequence partially anchylosed, and could not be flexed more than to an angle of 45 deg. with the operating table. The patient, too, was *sixty-nine* years of age, and had previously undergone several lithotrity operations.

The late Mr. Teale, of Leeds, published a record of twelve cases of median lithotomy, with eleven recoveries ; and I may mention his opinion that the operation seemed "not unlikely to supersede both lateral lithotomy and lithotrity." In Glasgow, Dr. Buchanan's operation, which is essentially a median one, still maintains its high repute. Professor MacLeod informs me he rarely does any other lithotomy operation. Allarton's statistics give 139 cases of the median operation, with 13 deaths, or a little over 9 per cent. The most remarkable statistical result, however, that I have heard of is that of Prof. Rizzoli, of Bologna, who in a decennial period operated on 41 cases by the median method, and in all with uniform success. With such statistics as these one cannot but be deeply impressed and filled with wonder that the operation has not obtained a wider recognition than it has already achieved. If there be truth in the axiom adduced by Mr. Richardson in his excellent paper, to which I have already referred, and which axiom has been accepted as such by the greatest lithotomists that have yet lived, that "the less extensive the cutting, consistent with space for the removal of the stone, the greater the chance of the patient's safety," we must admit that it applies with peculiar force to median lithotomy.

CHRONIC PSORIASIS, OR LEPRA VULGARIS.(a)

By A. S. MYRTLE, M.D.,

Consulting Physician to the Harrogate Bath Hospital.

THIS disease has been and still is looked on by some authorities as identical with that leprosy we read of in the Bible, and which proved a "plague" to the ancient Israelites, requiring for its treatment the enforcement of the most absolute separation of the sick from the healthy, and the destruction of every material which had exhibited the smallest sign of having been smitten with it. Without doubt many of the symptoms of the lepra of to-day correspond with the description left us of that of the time of Moses. The scales are white ; when removed there is the raised red spot. These spots spread ; the parts of the body affected are the same ; but the hairs do not whiten, and the lepra we now see is eminently non-contagious, and its white scales do not attach themselves to the skins of beasts and walls of houses. I think it highly probable that psoriasis was as common among the ancient Jews as it is among ourselves, and that it would be found side by side with cases of contagious lepra ; but owing to the impossibility of recognising the one from the other from want of diagnostic power, the subject of psoriasis would be treated exactly as if he had been a leper. All skin affections must have met with the same fate, even boils, and we cannot wonder that this one in particular should have had the word unclean pronounced against it. At the present time psoriasis is frequently seen in many parts of the East, and the modern Jew shows evidences of its presence as often as his Gentile neighbour ; but we shall seek in vain for a cutaneous disease to answer the description of the leprosy of Scripture, which possibly depended on the presence of a parasite, a white fungus which had the property of attaching itself and spreading, propagating on structures differing so widely in their nature, as wool and stone, as well as on man and beast. The traveller now as he passes from one Eastern city to another meets at its gates poor wretched objects, modern lepers, but these have nothing in common either as regards the history of their disease, the local and constitutional symptoms it presents, or its inevitable consequences to their retrospective namesakes.

Psoriasis stands next to eczema as regards frequency. It is very seldom seen in children under ten ; frequently after that age, where it is hereditary, we may detect one or two isolated patches of a slightly reddish hue, not very scaly. These often disappear without treatment, return again in the spring or autumn, until puberty is passed, when the eruption becomes more pronounced and persistent, showing a decided preference for the knees, elbows, outside of thighs, legs, and hairy scalp, but seldom affecting the face or hands. If the scales are allowed to accumulate, they become white and of a pearly lustre ; but as they are liable to removal from the friction of clothing, washing, &c., they seldom present this peculiarity, and for the most part are of a yellowish colour and opaque. No constitutional disturbance precedes or accompanies the eruption, and barring its unsightliness, the individual is in perfect health. Of the cause of this disease we know nothing. Why certain little patches of skin should become

(a) Read before the Leeds and West Riding Medico-Chirurgical Society.

over-vascular, and why this should lead to excessive cell growth, and cell growth of a normal character, although in too great abundance, is a problem still to solve. Of all diseases of the skin I believe it to be the most capable of transmission from parent to child, with a tendency to increase in virulence as it descends. However virulent, I also believe no disease is so little apt to impair the general health if left to itself, and that in time—it may be a very long time—it wears itself out, leaving the patches of skin in a perfectly healthy condition. This I have also noticed, that some cases respond to treatment readily; others presenting the very same features defy all medicines; and often in these cases I have seen great mischief result from too prolonged courses of powerful and poisonous drugs. Some medical writers have affirmed that psoriasis is very often associated with pulmonary consumption. I agree with them, but connect the lung evil with the remedies employed to cure the rash—not with the rash itself. It is not possible that the economy can permit the exhibition of accumulative poisons for months and years without suffering in one or other of its parts; above all, arsenic and mercury ought to be administered so as to avoid their doing permanent injury to the constitution, whilst they can in most instances effect but temporary good to a harmless eruption. Others look on it as a sure indication of gout; and I admit that the two are frequently found to exist at the same time in the same subject; yet I hold them to be perfectly independent as regards causation, and therefore requiring at our hands some discrimination in their treatment. Perhaps the reason that psoriasis has been so often looked on as of a gouty nature may be accounted for by the fact that when it makes its appearance for the first time it very generally does so after adolescence, the very period when gout is apt to show itself. When it is hereditary it very often appears at an early age, and continues to maintain its hold till the individual reaches that time of life when gout may be expected, and so we have the two running in couples. Yet I am inclined to view them as distinct diseases, and when they do exist in the same individual, in order to deal with them successfully they must be dealt with separately. I have often found that, although the patient got rid of all traces of gout, his skin remained as full of scaly patches as ever. This, I think, would not be the case if there was that intimate connection between the two which some maintain. My experience leads me to believe that psoriasis is little under the influence of any other disease, whether chronic or acute; these run their courses, leaving the patient, as far as the eruption is concerned, just as they found him. Certain seasons have much more power over it; in some it disappears entirely during the winter months, in others during the summer; but I rather think a hot dry summer is more apt to aggravate it than any kind of weather, and I have frequently seen it affect parts during or after such a season which it had never encroached upon before. If psoriasis is not affected by the superaddition of other aberrations from health in any one suffering from it, however extensive it may be, it does not in any way interfere with the general health, or even comfort of the patient. It must have a depressing effect on the spirits, especially when females are the subjects, but that is often greatly increased by the lowering effects of arsenic and iodide of potassium, and might be very much lessened were they made aware of the perfectly innocuous nature of their complaint, and the possibility of its being kept within bounds. In this country psoriasis is much more frequently met with in people with fair and fine skins than among dark, and shows a decided preference for the strong and healthy. Various writers maintain that it is usually associated with some form of debility of a constitutional character; but this has not been my experience. It is confined to no race or country, and presents the same features wherever it is found. As to the varieties of psoriasis, I have nothing to say; they all present two or three very distinguishing features in common, the first being cell proliferation, the second that this excessive growth neither injures the general health nor leads to any ulterior change in the skin itself; third, that it is most difficult of cure, and when cured, apt to recur; and lastly, that it is hereditary.

Two cases have just presented themselves in proof of the two last facts. I have been called to a gentleman, æt. 78, on account of bronchitis. I also find him the subject of extensive and continuous patches of psoriasis, and he tells me he has never been free of it since he was fourteen years of age, that he has never been treated for it, and that the only application he ever used was a rag soaked in cold water. He is a hale, active man, and rides and walks as vigorously as he did when in his prime. The other case is a girl of eleven covered with psoriasis. The spots vary in size from a pin's head to a sixpence, involving the whole skin except hands and feet. Two years ago her brother, when eight, suffered in the same way. Last year a sister, twelve, had it and now the mother, for the first time in her life, shows a few places on one cheek, and one patch on left shoulder. She tells me that her sister is affected likewise, and that they can trace it back to the grandfather. All are fair-skinned, very healthy and robust.

As to treatment, this involves constitutional and local remedies. Of the former, by far the most powerful and specific against this cell growth are the different preparations of arsenic; in fact, these are the only medicines which act directly on this eruption; other medicines may do so indirectly by improving the digestive organs, and giving tone to the system generally. But arsenic alone seems to be able to cause its disappearance. Unfortunately, this medicine cannot be borne by all patients alike, and many even refuse to get well under protracted courses of the drug. In all its exhibition must be carefully watched, as, if pushed too far, or given where from idiosyncrasy it is not admissible, most unpleasant and occasionally serious symptoms arise. Local remedies may be divided into two kinds, soothing and stimulating. Among the soothing, baths of different kinds must be held as holding the first place, and if properly carried into action, they prove of immense value. They soften the skin, remove the accumulated scales, and thereby enable other applications to reach the hyperæmic vessels. I have known a three months' course of the mild sulphur baths completely remove every vestige of psoriasis in cases of very long standing and extent. I have repeatedly found that the daily immersion in a bath of cold water summer and winter at the ordinary temperature, remaining under the water as long as the patient can bear it (in very cold weather one minute to two, in very warm twenty minutes to thirty may be borne), has had a very decided influence in keeping this disease in check. But this treatment requires a vigorous constitution to start with, and above all, a strong heart to ensure reaction.

Where baths cannot be had, water dressing with oil-silk coverings, act much in the same way. Of the many soothing ointments, I give preference to cocoa butter, as the most cleanly and least apt to oxidise. Where stimulant local measures are needed, we use soft soap, the preparations of tar, vegetable and mineral, mercury, iodine and their combinations, all possess great virtues, and if judiciously applied, may keep the disease in subjection. Change of climate frequently proves eminently curative; sometimes from the sea coast to inland, or the opposite, very generally from a low to a high situation, will be followed by a rapid subsidence of the rash. I have met with many patients who assure me that as soon as they get into the mountainous regions of Switzerland their skins become free from every spot. Unfortunately this does not last longer than their sojourn among the heights, for as soon as they return to the plains the eruption again shows itself.

Whenever psoriasis is accompanied with symptoms of derangement of the stomach, liver, or other organ, the treatment must first be directed to that quarter, as it would be unreasonable to expect that the skin should respond to remedies when its condition was aggravated by the presence of such complications. Should there be general debility, measures for restoring strength must be first put in force in the form of tonics and nutrients. If the blood has become loaded with impurities, these must be

got rid of by the exhibition of medicines which act as depurants, and thus having restored strength and eliminated morbific elements from the blood, we may fairly hope to obtain satisfactory results from the local and constitutional remedies which experience has proved useful in the treatment of this affection.

In dealing with all skin diseases, more attention ought to be paid to the character of the skin itself than is generally the case. There is too much routine practice here, and the different forms of cutaneous disease are very often treated according to their names, without reference to the varieties of texture and functional activity which we meet with so frequently. The skins of the young will not bear the same treatment as those of older growth, and I have found, or imagined I have found, that the skins of patients coming from the northern parts of our own country stand rougher treatment than do those from the southern. Dr. Tilbury Fox, in speaking of the different modes of treating skin diseases in England and the Continent, points to the fact that here we could not use the same strong measures which are resorted to in France and Germany, and he further observes, "Differences in the pathological conditions of the same disease, as seen in London and Vienna, are observed, and such being the case, merely even *d priori*, one may expect that some differences of treatment may be required to suit the respective constitutional conditions which result from the operation upon individuals of different modes of life, climatic influences, particular diet, habits, and a dozen other like things."

My remarks apply to true psoriasis only, the distinguishing feature of which is that in almost all cases you have the knees and elbows exhibiting spots, and these generally occupy the very centre of the joints, where they will remain stationary for great periods of time, in spite of everything. The eruption, wherever it appears, is of the same character, and generally shows a disposition for the skin on the outside of the extremities. The scales are deposited in layers, and are very adherent, and when the hairy parts of the body are affected, the hairs themselves remain perfectly healthy. The diseases of the skin most frequently mistaken for psoriasis are syphilitic eruptions and ringworm. Of the former, we have a very common form of syphilitic psoriasis, but the rash may be easily distinguished from true psoriasis by attention to a few of the following facts:—1st. The fact of previous syphilitic poisoning; 2nd. The presence of febrile symptoms; 3rd. The character of the eruption, which in the syphilitic form generally appears most abundantly in those parts of the skin least affected in the true—the insides of the extremities, palms of the hands, and soles of the feet. The scales are smaller, less adherent, and vary in shape. The colour of the hyperæmic patches is of a dusky brown; and on examining the mucous membrane of the mouth you will generally find patches on the tongue and throat, with fissures. These I have never found in true psoriasis. Then we have the action of remedies to assist in our diagnosis. In syphilitic psoriasis mercury and iodide of potassium soon pronounce in favour of a specific origin, whereas in the other they exercise no power except for mischief. In tinea circinata we have circular patches, as in psoriasis, but these are slightly raised. The rings are found to consist of small vesicles or papules, giving off a furfuraceous dust, unlike the scales of psoriasis, and if examined these will be found to contain traces of the trycophyton tonsurans; the rings widen in circumference, leaving healthy skin in their centres; and when they encroach on any part covered with hair, the hairs dry up, bend, and are speedily nipped across by the parasite.

THE Alexander prize, consisting of £50 and a gold medal of the value of £5, has this year been awarded to Surgeon-Major Porter, Assistant Professor of Military Surgery, Army Medical School, for his essay on the various forms of Stricture of the Urethra, their causes, consequences, and treatment.

VALEDICTORY ADDRESS

TO

THE SURGICAL SOCIETY OF IRELAND,

DELIVERED BY

EDWARD HAMILTON, M.D.,
Fellow and President of the Royal College of Surgeons in Ireland.

GENTLEMEN,—In bringing our session to a close, I think I may fairly congratulate you that some useful work has been done, that we have each learned something, and that something has been added to the general stock of knowledge. A retrospect of the communications made to the Society will prove that the session 1875-76 has not been unprofitable. We have had exhibited to us many morbid specimens illustrating peculiar and unusual forms of disease. Papers have been read on debatable questions in surgery which have been carefully and thoughtfully dealt with, and placed before us with the greatest accuracy and most exhaustive detail. Our thanks are due to those of our members who have devoted so much labour and valuable time to those essays, which have been so interesting and so instructive. In a classified list of the subjects brought under our consideration we find—

AFFECTIONS OF THE BONES AND JOINTS.

Fracture of the patella	Mr. Croly.
Excision of the shoulder	Mr. Stokes.
Caries of the metatarsal bones ...	Mr. Wheeler.
Injury of the Spine	Mr. F. Porter. Dr. Barton.
Necrosis of the cuboid and cuneiform ...	Mr. Croly.
Division of external lateral ligament of knee	Mr. Kelly.
Enchondroma	Mr. Wheeler.

OPHTHALMIC SURGERY.

Melanosis of the eyeball	Mr. Croly.
Transplanting conjunctiva of rabbit ...	Mr. Swanzy.
Cataract	Dr. Jacob.

VASCULAR SYSTEM.

Torsion	Dr. M'Donnell.
Thrombosis	Mr. Wheeler.
Aneurism	Mr. Tyrrell.
Topical blood-letting	Dr. Mapother.
Tracheotomy in croup	Mr. Thompson.
Lithotomy	Mr. Stokes. Dr. Barton.
Ovariotomy	Mr. Croly.
Umbilical hernia	Mr. Croly.
Medullary sarcoma of testis	Mr. Croly.
Hæmorrhoids	Mr. Croly.
Chronic rheumatic arthritis	Dr. Kennedy.
Nervous diarrhœa in females	Dr. Swan.

STATE MEDICINE.

The ropes used in hanging	Prof. Haughton.
Antiseptic Surgery by salicylic acid ...	Prof. Bennett.

At the opening of the session it was my painful duty to record the death of one who was to have been our vice-president. At its close I am called upon to notice another loss which we have sustained by the death of Dr. Morgan, a member of the Council of the Society, and one of its most active and energetic workers. The appalling suddenness with which that fatality fell on the profession was in itself enough to startle and dismay even the most thoughtless. Meeting death as we do in so many varied forms, it becomes no doubt divested of much of its solemnity and its impressions of horror; but when it strikes with such fatal rapidity one of ourselves, does it not make us pause in the race of life and ask the momentous question—*Who next?* "Two men shall be in the field, one shall be taken and the other left." I shall not detain you with any prolonged *éloge* on the life and character of him who has been taken from us; they are well known to you all. As a public man he was progressive, bold in his conceptions, prompt in action, and possessed of high powers of administration. As a debater at our meetings he was clear, eloquent, and incisive. He originated many important and instructive discussions in this room. His powers as a teacher were equalled by few, surpassed by none. In private life he was all that is good; his cheerful and sunny nature, his joyous disposition disarmed his enemies and endeared him to his friends. His last mo-

ments were characterised by cool unflinching courage as calmly and heroically contemplating his approaching dissolution. He gave those directions and met the necessities which his untimely death was about to occasion. He was sustained by the simple faith of a Christian man, giving one more proof of that which I have endeavoured to impress on the profession and the public, that the educated and philosophic surgeon need not be an atheist. Cut down as a flower, when about to reap the golden harvest of the best of his life spent in the labours of his profession, John Morgan will long live cherished in the memory of his colleagues, his pupils, and his friends. In conclusion, gentlemen, permit me to thank you for the courtesy and consideration which has been extended to me when occupying this chair. You have rendered my duties light and pleasing, and I shall ever look back on my year of office as your president with the most grateful and happy recollections. Farewell.

Transactions of Societies.

SURGICAL SOCIETY OF IRELAND.

THE concluding meeting of the session was held on Friday, April 7th, 1876, the President, Mr. E. HAMILTON, in the chair.

FRACTURE OF THE BASE OF THE SKULL.

Mr. CROLY exhibited a specimen of fracture of the base of the skull, and he thought it of so much interest as to be worthy of bringing under the notice of the Society. On Monday week last the little girl from whom the specimen was removed was knocked down by a horse drawing a heavily-loaded cart. She was admitted into hospital at half-past one o'clock on the same day, with mixed symptoms of concussion and compression of the brain. The symptom that attracted his attention most on seeing her was very smart hæmorrhage from the right ear, in addition to which there was very copious hæmorrhage from the left nostril, and on examining the face closely it was found that there was sub-conjunctival ecchymosis of the left eye. There was vomiting of blood, and that vomiting he regarded as partly due to the concussion and to the blood from the roof of the nose, which was swallowed. The strange point about this case was that the girl recovered from the symptoms of compression which afterwards set in. She recovered her consciousness, and became so natural in every way that he was in great hopes she would have lived. After she recovered herself sufficiently he noticed that she had facial palsy at the right side. Although she had hæmorrhage from the right ear, facial palsy, hæmorrhage from the left nostril, ecchymosis of the left eye, and sub-conjunctival effusion, from these symptoms he diagnosed the fracture as extending over a portion of the right temporal bone, the left side of the ethmoid bone, and the left orbital plate of the frontal. The girl continued to improve until the Friday following, and at about four o'clock on the morning of Saturday she got a sudden fit of screaming. He was sent for, and on arrival found the girl suffering from all the symptoms of inflammation of the brain. Everything possible was done to relieve those symptoms, but without avail, and she died on the Sunday morning following, after having been six days in hospital. He made a post-mortem examination, and the first thing he desired to show was the condition of the brain which he exhibited. The vessels of the brain were very much congested. The brain itself was very vascular on cutting into it, but on examining the membranes at the base of the brain, he found a quantity of green coloured pus with lymph effused—the result of inflammatory action. There was no clot of blood found at any part, but on examining the skull for the fracture, he found that it passed through the occipital bone, through the lateral sinuses at the right side, through the petrous portion of the temporal bone—explaining the hæmorrhage at the ear and the facial palsy—the body of the sphenoid, the left side of the ethmoid, the left orbital plate of the frontal bone, and down to the nose. They therefore had the fracture extending from behind the mastoid process at the right side to the left nasal bone—explaining all the symptoms exactly as they occurred during life. The skull was extremely thin—indeed, he had never examined so thin a skull in a child of the age of the patient. The occipital bone was as thin as the orbital plate of the frontal bone.

DISEASE OF THE KNEE-JOINT.

Mr. W. I. WHEELER said the specimen which he exhibited was taken from the knee of a patient who was admitted under his care into the City of Dublin Hospital. The patient was a young man 19 years of age, and was resected on Friday last. On admission the knee was slightly flexed, and, as compared with the other joint, there was considerable enlargement. At the centre of the patella the leg was an inch and a quarter larger than the other. There was considerable pain on pressing the patella, but no thickening. On pressing the head of the tibia there was considerable pain—more than at the femur. He performed the operation by the "H" incision, and on opening the joint some pus escaped. The anterior crucial ligament was entirely ulcerated through, and the posterior crucial ligament slightly ulcerated. The cartilaginous surface was considerably eroded, but on section it was found to be healthy. Before making a section of the tibia they could observe three perforations; one passed down into the bone for nearly three-quarters of an inch. The semilunar cartilages were entirely eroded, with the exception of portions of the internal one, and presented appearances of granular degeneration. On making a section of the tibia the abscess was seen to pass down to the extent of three-quarters of an inch, and on gouging that portion away the rest of the tibia was found to be entirely healthy. About half-an-hour before coming to the meeting he saw the patient, and he was progressing as favourably as could be expected. On an examination of the patella, the external facet was found perfectly healthy, the lower and external ones eroded and partly carious.

Mr. CROLY then exhibited the bladder and urethra of a man who died a couple of days since at the City of Dublin Hossital. The man was admitted under Mr. Croly's care with organic stricture of the urethra at the termination of the spongy portion. The stricture was an extremely tight one, and he could only get a very small whalebone bougie through it. While he was treating the case by the dilatation method the patient had a most acute attack of hæmoptysis, and died in a few days, and Mr. Croly removed the urethra and bladder. The bladder was very small, and was in a state of chronic inflammation. A few days before his death he complained of pain in the perinæum, and Mr. Croly found a large abscess in the region of the perinæum, which, however, did not prevent his passing water, and from the man's extremely low condition he (Mr. Croly) did not interfere with it. The abscess corresponded with the membranous portion of the urethra, and was formed by it. The urethra was dilated and the right kidney considerably enlarged; the openings of the ureters were also very large. The point of great interest in the case was the extensive disease about the stricture, so that in dealing with the case they had not only stricture of the urethra to deal with, but the very large pouch formed—in fact, the disorganised condition of the urethra.

Professor STOKES then read his paper on

MEDIAN LITHOTOMY,

which will be found on page 334.

The PRESIDENT said he had had two cases of median lithotomy, both for the extraction of catheters, and both of which were successful.

Professor STOKES—I am sorry I did not know that, or I would have alluded to them.

The PRESIDENT, in continuation, said there was an interesting point in connection with the subject of the paper that anatomists might speak of, and that was the question as to whether or not the posterior layer of the triangular ligament would be wounded in the operation. He thought it was impossible to divide the prostate gland without wounding it if the incision be carried too far cut; *that*, he thought, was the great danger. The pelvic fascia passed to the side of the prostate, and as long as it remained intact it formed a complete barrier between the cellular membrane of the pelvis and the cellular membrane of the perinæum. The capsule of the prostate gland should and must be divided in lithotomy. He could not see how it could be avoided, provided that the division was not carried out to the extreme point of the margin. In that, he thought, consisted the great safety of limited incisions.

Dr. BARTON would wish to know whether the favourable statistics of the median operation—whether the operations in

most of those cases were performed by Allerton's method of dilatation or with the incision which he advocated. Mr. Allerton, in recommending dilatation, if he (Dr. Barton) remembered rightly, did so on the ground of safety, and it would be important to know, before concluding upon the question of incision with regard to the favourable statistics of the cases of Mr. Cadge, Mr. Stokes, and others—exactly how they were in this particular part of the operation—in the second stage, and dilating of the prostate.

Mr. CORLEY said there was no doubt that if the operation was performed in the way that Mr. Allerton recommended one could scarcely help meeting the top of the prostate. As well as he (Mr. Corley) remembered, Mr. Allerton told them to feel the back of the knife through the rectum as it passed, however superficially. If they continued to feel, and kept on closely with their finger, they must necessarily "nick" the top of the prostate. He remembered doing so himself, and he could feel, on putting his hand into the bladder, the two tips of the divided prostate. He was glad to hear so high an authority as the President state that the capsule must be cut in the lateral operation. He (Mr. Corley) could not conceive how an opening sufficiently large could be made without cutting part of the prostate. He thought any one who had dissected the perinæum would know that the posterior layer of the triangular ligament remained intact, and formed the capsule. He thought too much stress had been laid on the operation of dividing the capsule of the prostate. He did not think there was the same liability to infiltration of urine that people thought.

Mr. H. G. CROLY said the question brought forward by Professor Stokes was one that could be narrowed into a very small compass. In the first place, they could not perform any operation on a child except the one—at least, he did not think any surgeon would like to perform median lithotomy on a young child. It was possible, but he thought cutting for stone depended very much on the mode in which a man held his knife. He thought the cases for median lithotomy were very small hard stones that could not be crushed, or foreign bodies, such as catheters. He happened to have had 7 or 8 cases of stone, and he could not call to mind a single case in which he could have performed median lithotomy. He thought the selection of the cases was as important as the selection of the incision. With regard to hæmorrhage in lithotomy, he had seen Mr. Tufnell cut 7 or 8 cases, and he never saw one stone operation in which hæmorrhage occurred. He was quite aware that it did occur in lithotomy, but when it occurred in children, it was attributed either to an anomalous distribution of the arteries or the incautious use of the knife. With regard to the opening of the capsule of the prostate, he did not think they could perform any lithotomy operation without cutting the capsule of the prostate, and he thought the free division of the prostate and its capsule, tended to prevent the infiltration of urine, and it was a well-known fact, since the time of Liston, that they ought to cut stones out of the bladder, and not *tear* them. As to median lithotomy superseding the lateral operation, he thought that was out of the question altogether. He thought they must perform median lithotomy in the cases of catheters and small stones, and that they still must adopt the lateral operation in the majority of cases.

Mr. F. T. PORTER thought an operation that required a considerable amount of dilating force was much worse than a severe incision. They all knew that India was the place where lithotomy was more successful than in any other part of the world, and he understood that it was the lateral operation that was performed there with such success. With regard to the statistics Mr. Stokes had referred to, he had stated that the climate of Bologna was quite different from the climate of Ireland. He (Mr. Porter) thought if the same number of operations were performed here or in England they would not be as successful.

Professor STOKES in reply said he must re-echo what Mr. Corley had said in reference to his satisfaction at hearing the President state that he did not believe that the operation of lateral lithotomy could be performed without wounding the capsule. It was also satisfactory to find that Mr. Croly considered that not only was it necessary to do so, but also that it tended to prevent rather than to promote the chances of urinary infiltration. In reference to Dr. Barton's question as to whether the cases he (Mr. Stokes) had alluded to were treated solely by dilatation or by incision, he might mention that they were done entirely by dilatation—in fact, as he mentioned in his communication. Sir Henry Thompson and Mr. Allerton both suggested the desirability in certain cases of converting the operation into medio-lateral operation; but they did not state, nor did any of the other writers on the subject—Mr. Teale, Signor Rizzoli—that they did that by making an incision into the prostate. In reference to Mr. Croly's observation as to the operation being so very inapplicable to young subjects, he might mention that Mr. Teale—an authority whom Mr. Croly was often fond of quoting himself—gave cases where he had performed the operation in very young children, and also those of the ages of four, eight, and nine years, in Signor Rizzoli's work. He (Mr. Stokes) might mention that of the forty-one cases of calculi that they had operated on by the median plan, thirty-one were in patients between the ages of ten and fifteen years, so that as far as the statement of the operation not being applicable to young persons went, the experience of the surgeons he had mentioned appeared to be that it was specially applicable to them. Another remark Mr. Croly had made with reference to the operation superseding the lateral one, he (Mr. Stokes) did not think that he made any remark in his communication which would tend to show that he thought it should supersede that operation. He merely meant to say that the median operation deserved greater consideration than it had hitherto enjoyed at the hands of surgeons. With reference to Mr. Porter's remarks connected with India and Italy, he (Mr. Stokes) had never himself visited the tropics, and he was not aware of the nature of the operation performed in that distant region, but at the same time he was aware that they were very successful. Concerding Mr. Porter's observations with reference to the climate of Bologna, he (Mr. Stokes) wished they had a little more of it here in this country. The operations there were successful, but he had no doubt that if the cases had been operated on here they would have been equally so.

Dr. F. T. PORTER read his paper on

SPINAL INJURY,

upon which there was no discussion. The paper will appear in our next issue.

The PRESIDENT then read his address at the close of the session.

By permission of the meeting,

Mr. ROSS, of the firm of Ross and Co., Ellis's Quay, exhibited an invalid's chair of recent design. The new chair, the frame of which is of iron of light construction, possesses all the advantages of the Merlin, with the additional merit of being rendered so portable as easily to be carried when travelling. By removing the arm rests the chair can be folded up into an exceedingly small space, and in an instant can be reopened and rendered fit for use. It stands on casters, and projecting from the arms of the chair are two handles, one on each, and on these being turned the invalid is enabled to propel himself in any direction desired. The chair, which has a foot-rest attached, is richly upholstered in crimson velvet. In answer to several inquiries from members,

Mr. Ross stated that the price of the chair was fifteen guineas.

The Society then adjourned until next session.

THE annual meeting of the General Medical Council will not be held at so early a period as we had hoped, but it is earlier than usual, consequently a step in the right direction. Wednesday, May 24th, is the date of meeting.

THE Council of the British Medical Association appear to be still in a fix about the place of meeting for 1876. The profession in Brighton is offended with the Association, and refuses its patronage. Sheffield next steps in to offer a welcome; but the profession of that town and neighbourhood showed such a lack of interest and sympathy, that only between twenty and thirty responded to the invitation to be present at the meeting recently held in that town. What the Council will do under existing circumstances is at present unknown.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, APRIL 26, 1876.

RECENT REPORTS ON CHOLERA.—CONDITIONS OF ITS TRANSMISSIBILITY.—No. II.

Now with regard to the conditions of the transmissibility of cholera, the International Sanitary Conference recently held at Vienna came to the unanimous conclusion.—That cholera is transmissible by man coming from an infected locality, that man is not considered as the specific cause apart from the influence of locality, and that he is regarded as the propagator of the disease when he comes from a place where the germ of the disease already exists. They also unanimously concluded that cholera can be transmitted by personal effects coming from an infected place, that the disease may be propagated by drinks, particularly by water, that the surrounding air is the principal vehicle of the generative agent of cholera, but that in the immense majority of cases the restriction of the malady by the atmosphere is restricted to the close vicinity of the focus of infection. Now for all practical purposes this knowledge is very complete, but still there are many points respecting which more exact information is desirable. In the first place there is a great deal of doubt as to the precise manner in which the cholera poison is transported from the diseased to the healthy. Pettenkofer, who has quite recently written a monograph on "Cholera: How to Prevent and Resist It," which has been ably translated by Dr. Whiteside Hime, would imply that the cholera patient does not, as is generally supposed, himself generate any of the poison by which the healthy are infected, but that he is merely the *carrier* of the cholera-germs from an infected locality. As we have already mentioned, he says that in those cases of supposed contagion the patient had conveyed with him from the cholera-district so much of the cholera-poison that there was enough to infect the other persons who were attacked. And when a person contracts the disease by coming into contact with the wearing-apparel of the diseased, it is not, he says, "because they have belonged to a cholera-patient, but because they have come from a cholera-district." We do not, however, see that these views are borne out by the various reports on cholera that have been published from time to time. Were these views perfectly correct, we should expect to be constantly hearing of persons, themselves proof against cholera or any other contagion, coming from infected districts and spreading the disease far and wide. But such is not the case; on the contrary, although a healthy person may act as a mere carrier of the poison, it almost invariably happens that the individual or individuals who have started an epidemic of cholera have been attacked, and often fatally attacked, with the disease before it was communicated to other people. If, moreover, the cholera poison is not generated *de novo* from a cholera patient, how can we account for those cases (many of which may be found in the American Reports) in which the contagion was traced to drinking water that had been contaminated with cholera evacuations. And, lastly, if the generative principle of cholera is not constantly renewed by emanations from the patient himself, we could scarcely account for the rapidity with which the disease becomes diffused over areas of large extent, and we should certainly expect, if the above views were correct, that there would not be much difficulty in stamping out the disease on its first appearance in any particular locality. For example, if an infected person coming into a healthy district acted as a carrier only of the cholera poison from the infected district, and that by means of his clothes or any other articles belonging to him, it follows that it would be comparatively an easy matter to prevent the disease spreading any further, as all we should have to do in such a case would be to destroy at once everything belonging to him.

Then, again, as to the part played by the evacuations of the patient in the propagation of the cholera we have still much to learn. Pettenkofer believes that the excretions of cholera patients have very little to do with the spread of the disease. "It is not impossible," he says, "nor even improbable, that the excretions in themselves are quite harmless, and that a house, *e.g.*, becomes a cholera-den, not because it has a privy into which the excretions of a cholera patient have been conveyed from without, but in a very different and hitherto quite unrecognised manner.' We are sorry that very little light is thrown upon this important question by the Report on Cholera by Mr. Netten Radcliffe, which is an elaborate but very general account of the transportation of the disease from one place to another; but on turning to the American Reports, we have more precise information on the subject. So far from sharing the doubts entertained by Pettenkofer, the American physicians, in their Report to Congress, insist upon the truth of the proposition "that the active agents in the distribution of the cholera poison are the dejections of persons suffering from the disease in any of its stages, and that in these dejections there exists an organic matter which, at a certain stage of decomposition, is capable of reproducing the disease in the human organism to which it has gained access." This statement, which will remind our readers of the similar views entertained by our own countryman, Dr. William Budd, receives strong corroboration, not only from numerous experiments that have been performed on the lower animals, but also from many cases described in the American Reports. For instance

Dr. Macnamara cites a case in which a small quantity of the dejecta of a cholera patient was known to have been accidentally washed into a vessel containing water. The mixture, after having been exposed to the heat of the sun, was swallowed by nineteen men, five of whom were afterwards seized with cholera. Cholera was not present at the time, nor had it visited the locality at which these cases occurred for several years. Again, at the village of Addieville, Illinois, some cases were clearly traced to a cholera patient having deposited his dejections in a barn to which the people afterwards infected had been in the habit of resorting for the same purpose.

Another important question upon which much light has been recently thrown is with respect to the influence of all kinds of filth and bad drainage upon the propagation and fatality of the disease. In his brief but able introduction to Mr. Radcliffe's Report, Mr. Simon very justly insists upon our classsing cholera as a filth-disease, and upon the fact that "conditions of filth, and especially filthy conditions of water supply, are the main facilitating conditions for the dissemination of the disease;" and another of the propositions formulated by the American reporters is "that the virulence of the cholera-contagion is influenced by the hygienic condition of the population, and not by any geological formation upon which they may reside." The truth of this view is well shown in the American Reports, in which all the reporters appear to have paid particular attention to the physical features, the hygienic conditions, and the water supply of the various localities in which outbreaks of the disease occurred. We can scarcely turn over a page without having evidence that it was in the most filthy places, and amongst the most filthy individuals that cases of cholera were most numerous and most fatal. "Alleys reeking with filth, privies unemptied for years, and running over with the foul accumulations, all kinds of garbage thrown into the streets, drains from cesspools and washhouses emptying themselves into rivulets whose waters run in close proximity to springs of drinking-water, the ground around the infected premises reeking with the wash from cesspools, filthy state of the dwellings, and bed-clothes and floors repulsive from the cholera-excreta from the stomach and bowels of their former occupants, low, sunken, damp and marshy localities—such are some of the conditions which appear to have assisted the propagation and fatality of cholera in a large majority of the many infected districts of the United States.

It remains to make a few remarks respecting the influence of locality upon the disease, or, as Pettenkofer calls it, "*the local and temporal disposition*" of the place. It was the opinion of the Cholera-Commission of Bavaria in 1854 that epidemic cholera only occurred in places situated on porous ground permeable to air and water, and in which water could be found at a moderate depth; and that places situated on impermeable soil (rock, &c.) were not visited by the disease, or only in isolated cases. And according to the views of Pettenkofer, the nature of the soil and state of the ground-water constitute one of the conditions without which an epidemic of cholera cannot occur. According to these views the cholera-germs, after remaining for some time in a damp soil, become ripe, acquire a poisonous character, and rising with the ground-air, float about in the atmosphere, through the medium of which the inhabitants are infected. Within the bodies of the infected the germs undergo a further development, and become enormously multiplied; but when they are expelled by the dejections they are not in a state to produce epidemic cholera *until after they have lain in a suitable soil for some time.* The supporters of this theory admit that a small quantity of "full-ripe seed" may infect a few persons directly through the medium of dirty linen, impure water &c., but they deny that these infected persons can originate an epidemic unless the local and temporal conditions be favourable; if unfavourable, "the place will escape in spite of the importation." According to these views, therefore, a *sine quâ non* of a cholera-epidemic is a damp soil impregnated with organic matter, a situation in which the soil is exposed to the action of the air as well as to moisture. And inasmuch as a porous ground acts like a filter which retains organic matter among its pores, it follows that porous soils are more liable to be contaminated with organic impurities derived from various sources than a soil of a more impermeable nature. Now the views of so able an investigator as Dr. von Pettenkofer are entitled to the greatest respect, and it was in deference to the opinions of that physician and his German *confrères* that the original wording of one of the propositions of the Vienna Conference was altered in the manner it now stands. The original phrase objected to was, "L'homme atteint de choléra est par lui-même le principal agent propagateur de cette maladie." The objection taken by Prof. von Pettenkofer was particularly to the words "par lui-même," and consequently to meet the views of the German delegation, the Conference unanimously adopted the expression which we have already quoted, viz.—"that man is not considered as the specific cause (*i.e.* of the transmissibility of cholera) apart from the influence of locality, &c." At the same time the gravest doubts may be entertained as to the absolute truth of these views. It is true that a soil which has become contaminated with organic or sewage matter is more favourable to the development of cholera than a soil which is free from such impurities. It is likewise true that the air of a house or district may be infected by emanations from a soil the ground waters and ground air of which have become in various ways impregnated with the cholera poison. The outbreak of the disease in Adair County, Kentucky, demonstrates in a remarkable manner the truth of the latter proposition. But that an epidemic of cholera cannot occur unless the soil has in the first place acted as a sort of nursery to the germs of the disease is certainly a proposition which very few will endorse. Cholera has prevailed so severely all over the world, that we believe with Dr. Edward Goodeve that it is not likely that the soil exerts much influence, and much less that it is an essential factor of the disease. As shown by Macnamara the large majority of the inhabitants of the world live upon alluvial soils; they are crowded together in cities, towns, and villages, and the lower classes when thus congregated especially suffer from diseases consequent on or aggravated by faulty hygienic conditions; and undoubtedly a careful examination of these Reports, coupled with what we know of the history of former epidemics, as well as a consideration of the rapidity with which one or two cases have over and over again led to extensive outbreaks of the disease (and taking, moreover, into consideration the success which

has in numerous instances attended strict hygienic precautions), leave no room for doubt that there are any other essential conditions of the transmissibility of cholera than those we have already noticed, and justify us in assuming that the existence of a cholera epidemic depends far more upon human intercourse and upon bad hygienic conditions than upon the nature or condition of the soil.

PROGRESS OF SANITATION AMONG THE INDUSTRIAL CLASSES.

Notwithstanding the efforts that the Government has been making from time to time to improve the sanitary condition of the industrial classes, we are being continually reminded of how much still remains to be done before we hear the last of even those more flagrant instances of sanitary neglect which the Government inspectors are frequently bringing to light. Some months ago we had occasion to call attention to the deplorable state of some portion of the working classes in the Black Country, and to the very hard, degrading and brutalising work that was thrust upon many of the women in the colliery districts; and now the recent reports of her Majesty's inspectors of factories again show under what pains and penalties, and under what insanitary conditions, many of our industries are carried on. That part of the report which is most interesting in a hygienic point of view has reference to the influence of certain employments upon the health of the people engaged in them, to the general *physique* of the manufacturing population, and to the hard work that is often enforced upon children of tender years. With respect to unhealthy occupations, Mr. Alexander Redgrave calls attention to certain facts which afford an additional illustration of those removable causes of disease which Dr. Richardson has so ably discussed in his recent work on "Industrial Pathology." Mr. Redgrave informs us how prevalent still is lead-poisoning among the work-people who are engaged in the white-lead works of this metropolis. He states that no general rules are imposed upon the manufacturer himself, that a great deal depends upon the precautions which the manufacturer may think proper to take, and that consequently much suffering still prevails among this class of workpeople. Moreover, the rapidity with which lead-poisoning is sometimes developed is well illustrated by a case which came under Mr. Redgrave's notice, and in which a woman was fatally attacked with colic after working at the factory only a few weeks. Attention is also drawn to the need of more stringent regulations in those trades in which mercury is used—to the cruel results arising from the cutting and preparing of mill-stones—and to the miseries endured by the workpeople engaged in the "flax wet spinning mills" of Dundee. With respect to the mill-stone cutting, the reporter says that men engaged in that occupation are to be seen in every stage of suffering, many of them representing the "shrunken, hectic invalid, whose frail body is actually wrecked by that cruel cough, and as to whom it is said, 'Oh, he won't last above two months.'" And with regard to the Dundee mills, it appears that in many of these places the temperature is above 80 degrees, the rooms are full of steam, and the floors are wet and dirty; while the clothes of the women and girls (who are the hands chiefly engaged) become very damp from condensed steam and the spray thrown off by the spindles. Nor must we omit to notice the scutch mills in Ireland, of which there are no fewer than 1380, and many of which appear to be very unwholesome and ill-ventilated establishments. The air in these places is full of the dust and spiculæ driven off from the flax, and the workpeople are consequently tormented with cough, thirst, spitting of blood, and other symptoms of phthisis. Ophthalmia is also a disease very prevalent among them, evidently arising from the irritation of the dust.

Although, however, much remains to be done in the way of improving the sanitary condition of our factories, the prospects are in many respects very encouraging. The compulsory adoption of precautionary measures, the improved methods of manufacturing certain articles, and even, as we shall presently see, the interests of the employers themselves, all combine to lessen the evils resulting from unhealthy occupations. Already in those establishments where full precautions are taken, ill-health and disease are reduced, says Mr. Redgrave, to a minimum. With respect to the trades in which mercury is used, we are informed that there is a new mode of silvering glass, which is innocuous, and which will probably supersede the old and more dangerous processes. In the case of a paper mill, a very ingenious method has been found out, by which the enormous amount of fine dust generated in these mills is speedily got rid of. Formerly this dust, which was allowed to pass through the windows into the open air, was a great nuisance to those living close to the mills, and a great source of mischief to the workpeople themselves; but now, by means of a couple of powerful exhausting fans, the dust is driven into an air-tight room, which is especially devoted to its reception, and which is emptied every fortnight. And then, with regard to the "flax wet spinning mills," we are told that one manufacturer has not only succeeded in remedying the evils above-mentioned, but has done so with pecuniary advantage to himself. By purifying the air for his workpeople he has at the same time improved the working of his machinery, which, being no longer clogged with the surrounding dust and moisture, works more freely and with much less wear and tear.

Mr. Redgrave also points out the evils resulting from the non-enforcement of the Agricultural Children's Act We cannot notice the educational part of the question, but we may draw attention to the fact that the competition now going on in some country districts between labour and education is not, as has been very justly observed, "merely a competition between 'school' and 'no school.' It is in some cases between school and street vice; in others between school and excessive toil, inflicting at a tender age irreparable physical injury." In these reports several incidents are related of the callousness with which hard work is thrust upon children of tender years. In reference to these, Mr. Redgrave often asked, "Do you love your child?" and was always answered in the affirmative, with the addition that, "My father made me work when I was seven or eight, and I mean to make my child work."

With respect to the general *physique* of our factory population, recent investigations are not very satisfactory.

Last October Mr. Baker, one of the factory inspectors, issued a circular to collect evidence as to the truth or not of a statement that had been made by Mr. Ferguson before a recent commission, to the effect that "there is a steady deterioration going on in the *physique* of the factory population." Most of the answers which Mr. Baker received certainly confirm the opinion of Mr. Ferguson. For instance, the report from Bury was, "that the children in factories are, as a class, and compared with children in other employments, of diminished stature and inferior *physique*." The report from Preston was that "a considerable proportion of children presented to me for examination are not only stunted in growth, but generally deficient in physical strength and development." And many of the other answers received were in much the same strain. As Mr. Baker's circular was issued to the "certifying surgeons," whose business it is to ascertain the health and bodily condition of the candidates for factory employment, we can place great reliance upon their reports. At the same time it must be remembered that the deterioration complained of is owing not so much to the sanitary condition of the factories as to various other circumstances contingent upon factory life. What these other circumstances are we have pointed out on a former occasion. A few months ago, when commenting on the Registsar-General's Quarterly Return, we directed attention to the frightful mortality among the children born in manufacturing districts. But these statistical returns take no account of the perhaps more unfortunate survivors, who, having been born with an hereditary tendency to disease, and exposed during their infancy and childhood to the more potent causes of acquired disease, naturally grow up with an enfeebled constitution, and presenting all those marks of physical deterioration described in the local reports above mentioned. Consequently we are not surprised to find in these reports fresh evidence of the deplorable and insanitary conditions at work in the factory districts. From their birth the children "are badly fed, early deprived of breast milk, and a pap consisting of bread and milk substituted for it." "The offspring are reared with the bottle and drugged by the mother." "Many of the boys smoke and chew tobacco." "Women work in the factory almost up to the very day of their confinement, and return again to work almost immediately after their delivery." Nevertheless, on the whole the prospect is becoming every day more favourable, and perhaps the great publicity now given to every social scandal and the great light thrown upon every blot upon our social system tend to exaggerate the present hygienic condition of the industrial classes as compared with what it was formerly. And we have no doubt that every year we shall hear less and less of those sensational stories with which these reports have been hitherto so freely sprinkled.

Notes on Current Topics.

Election of Medical Examiners at the Queen's University.

A MEETING of the Senate of the Queen's University was held at its office, Dublin Castle, on the 15th instant, at which the following members were present :—

His Grace the Duke of Leinster, Chancellor, in the Chair.

Sir Dominic Corrigan, Bart, M.D., Vice-Chancellor; Sir Richard Griffith, Bart, LL.D; Professor Moffett, LL.D; David Ross, M.A., LL.B.; the President Queen's College, Cork; Professor Renfern, M.D.; Professor Maxwell Simpson, M.D., F.R.S.; Sir Robert Kane, LL.D., F.R.S.; Rev. Robinson Scott, D.D.; Andrew M. Porter, Q.C.; John Thomas Banks, M.D.; G. Johnstone Stoney, M.A., F.R.S., Secretary to the University.

Dr. H. Charlton Bastian, F.R.S., was appointed Examiner in Medicine; Dr. William Stokes, Surgery; Dr. J. Guinness Beatty, Midwifery; Professor Pye, M.D., Materia Medica; and Dr. William Stoker, Examiner in Medical Jurisprudence, in the Queen's University of Ireland.

The foregoing announcement has created in Ireland a very profound feeling of dissatisfaction, and even of anger, amongst the medical profession. That the Senate should pass over their own graduates and professors, and the whole of the medical teachers in Ireland, to seek in London for an histologist to examine in medicine in Ireland, is felt to be little less than an insult to Irish physicians. We are sufficiently liberal to admit that the alienage of a candidate should not exclude him from such offices in Ireland if he possessed manifestly a special knowledge of his subject or a peculiar capability for examining, such as could not be found elsewhere. We, moreover, do not doubt Dr. Charlton Bastian's competency as an examiner; it would indeed be less than his reputation deserves if we did so, for were he less distinguished he might easily reach the level of an Examiner in the Queen's University; and we believe that in physiology and histology no more capable examiner for a London licensing body could be had. We recognise also the propriety of electing a person perfectly independent of the Queen's University, and of looking beyond the professors, teachers, or graduates of the University for examiners. The feeling of the medical profession in Dublin is that the Senate have greatly erred in seeking for a London examiner when material in all respects of equal quality and possessing superior claims on other grounds was to be had in abundance at home. English physicians would reasonably feel aggrieved if the whole of the teachers and practitioners in London were set aside in favour of a Dublin doctor, and they will understand that the election has given much annoyance, and has been construed as an insinuation that competent examiners are not to be had in Ireland. We sympathise with this feeling, but feel no surprise at the action of the Senate, who are noted amongst administrative bodies for a *gauche* way of doing things, and for a vacuity of common sense and discretion. If it were needed to make the Queen's University still less popular than it is, the Senate is just the body to effect that object, and they could hardly have adopted a more effective method than the appointment of a London histologist to an examinership in medicine. *Quem Deus vult perdere, &c.*

State of Diseased Cattle in Dublin.

THE report of Dr. Cameron, City Analyst, for the quarter ended March 31st, furnishes some startling statistics respecting the sale of diseased meat in Dublin. During the quarter the enormous quantity of 28 tons 3 cwts. of

diseased meat and otherwise unsound food were confiscated. Since Dr. Cameron established a systematic inspection of meat, &c., six years ago, 2,250,000 pounds weight of unsound and consequently deleterious food have been destroyed. One hundred persons were fined, some of them £20 each ; and thirty persons were imprisoned for various periods on being convicted of attempting to sell this poisonous food.

The late Mr. Campbell de Morgan.

In our last we announced the sudden death of this celebrated surgeon, whose loss is so deeply deplored by all who had the pleasure of his acquaintance. At the last meeting of the Pathological Society of London, the President, Mr. George Pollock referred to the heavy loss recently sustained by the Society in the death of Mr. de Morgan, who was one of the Society's Vice-Presidents. He said that everyone who had been connected with the deceased, whether privately or professionally, appreciated the excellent qualities shown by him as a surgeon, a man of science, and a gentleman. Personally he had known Mr. de Morgan for many years and had enjoyed many opportunities of admiring his excellence as a man of honour and integrity. There were very few who had laboured so much to maintain the honour of the profession. A resolution of condolence was then unanimously passed by the Society, conveying to the family of Mr. Campbell de Morgan their sense of the great loss which the Society and the profession have sustained by his death.

Royal Microscopical Society.

The President of this Society, H. C. Sorby F.R.S., gave a *soirée* to the Fellows and their friends on Friday evening last at King's College. The rooms were filled with objects of interest, articles of *vertu* and beautiful flowers, among which the ladies occupied a conspicuous place. The guests, among whom we noticed the President of the Royal Society, Dr. Carpenter, and a number of men eminent in this department of science, were highly gratified with many interesting objects exhibited, the most conspicuous among which were those exhibited by Mr. Sorby himself.

The Hastings Water Supply.

The Town Council, the Inspectors of Nuisances, and some of the inhabitants of Hastings, are still quarrelling about their water supply. Week after week the local papers contain complaints and contradictions, and the Council seems driven in a corner with its multitude of Councillors. Last week's *Hastings News* contains a letter from a physician resident in the town, stating the water is not only deficient in quantity, but contains living organisms to a serious extent, the writer having found a number of water-fleas in a tumbler of water drawn from the main supply a day or two previously. With such a reputation at stake, Hastings, as represented by those in authority, cannot afford to neglect these continual warnings and newspaper squabblings, or the profession may be driven to send their patients to other health resorts where such an important question as the water supply is better managed.

Longevity of Brain-workers.

Dr. George Beard, of New York, whose researches on diseases of the brain, and in electro-therapeutics, are well known and widely appreciated, assigns as a cause of the exceptional longevity of great brain-workers—1. That great men usually come from healthy, long-lived ancestors. 2. That a good constitution usually accompanies a good brain. 3. That great men who are permanently successful have a correspondingly greater will than common, and force of will is a potent element in determining longevity. The one requisite of great success is "*grit.*" 4. Great men work more easily than ordinary men. 5. Great brain-workers have not all been rich, nor all been poor. The majority have been most of the time surrounded with at least moderate comforts.

A Monthly Fasting.

Lieutenant Ertel, convicted of selling Austrian official documents to a foreign Embassy, has just been condemned to dismissal from the service, loss of nobility, and ten years' imprisonment, *with one day's fasting every month.* We have no doubt but that the latter part of the sentence is intended to add to the severity of the punishment, and perhaps it will have the desired effect, in so far as it may for a time deprive the prisoner of that pleasure which usually attends upon the gratification of our appetites. With regard, however, to the health of the lieutenant, we look upon this part of the sentence rather as a boon than otherwise, inasmuch as one day's fasting in a month is calculated to do more good than harm to a man whose close confinement is to last for years, who during all that time will only be able to enjoy a very limited amount of exercise in the open air, and to whom is now allotted that monotonous life which is common to all prisoners. What a capital thing it would be if medical men now and then prescribed a periodical fasting for their patients—for those patients, for instance, whose dyspeptic torments have been brought on by their own gormandising propensities, whose appetites are so often palled with the pleasures of the table, and whose stomachs nevertheless vainly sigh for that rest which their owners never allow them to have.

The Drama v. Intemperance.

Apropos of the leading article we recently had on the above subject, we are glad to see that Mr. Gladstone also thinks the question of amusements in their relation to intemperance is one deserving of public attention. In answer to a request that he would attend the next conference on Amusements *v.* Drink, Mr. Gladstone writes as follows to the Editor of the *Journal of Amusement* :—

Sir,—I have read Mr. Irving's address with great interest, and I think it does him great honour. That it does not exhaust the subject is no reproach to it. That subject is, in my view, to the full as important as I take it to be also difficult. I shall at all times be ready to give it the best thought I can bestow.

I remain, &c.,

W. E. Gladstone.

Hawarden Castle, April 17, 1876.

Our readers will remember that the article referred to was suggested by Mr. Irving's address, and although, as we stated at the time, that address did not view the subject in all its bearings, we could not but admit that Mr.

Irving's remarks "were well calculated to arouse the attention of thoughtful minds, and to soften down the prejudices which even now obtain among a certain class of the community."

The Birth-rate of Dublin.

In the Dublin district the births registered during the quarter amounted to 2,429, being equal to an annual ratio of 31 in every 1,000 of the population.

In the suburbs of Dublin the births registered amounted to 458, or only 27 per 1,000.

There was registered in London during the same period an annual birth-rate of 38 in every 1,000, in Glasgow 40 per 1,000, and in Edinburgh 33 in every 1,000.

Non-Academic M.D.'s.

A medical contemporary, writing of the recent Visitation at the Queen's College, Galway, says :—"This year 91 students had entered, being an increase of 17 over the year preceding. It was not stated, however, how many of these had matriculated merely for the sake of becoming medical students, as the Queen's University does not require from its candidates for medical degrees a single course in arts, or any test of general education save entrance."

The Reverend Professor Haughton, in a letter to another contemporary, says :—"As a Fellow of the Irish College of Physicians, I protest against the principle involved in this controversy, viz., that the title of physician is inferior to that of graduate, so far as professional merit is concerned. *If the University graduate in medicine be also a graduate in arts, he may fairly take precedence of a physician ; but if he be a graduate in medicine only, he is entitled to no precedence.*

The Plague in Mesopotamia.

According to the *Levant Herald* rather gloomy advices are still received from Mesopotamia. Hillah and Bagdad are still the chief centres of the sickness. In the former town, from the 13th to the 19th ult. there occurred 45 attacks and 25 deaths. At Bagdad, on the 19th ult., nine persons were attacked, and eight died ; on the 20th, eleven cases were reported, and of these four proved fatal. Dr. Millingen, of the Turkish Sanitary Service, has been sent from Syria to the seat of the epidemic, in company with two other doctors of the service. At Bagdad, a permanent sanitary commission has been instituted, one of the members of which is the physician of the English Consulate-General. It has been decided to reinforce the Medical staff at Bagdad by two additional surgeons, one from Constantinople, and the other from the sanitary station of Adalia, in Caramania.

Street Accidents.

Mr. Cross (10th inst.), in reply to Sir P. O'Brien, said that he had given instructions to the police authorities to make full investigation into the relation existing between the employment of covered vans and street accidents. He could give no information respecting the year 1875, as the returns had not been finally made up, but those for 1874 showed that out of 124 persons who were killed in the streets, 28 were killed by vans, 24 by light carts, 18 by waggons and drays, 15 by omnibuses, 14 by cabs and heavy carts, and none by covered vans. Again, out of 2,568 persons maimed, 1,716 were maimed by light carts, 624 by cabs, 375 by vans, 320 by broughams and carriages, 100 by waggons, and only 22 by covered vans. He had given instructions to the police to issue placards warning the drivers of light carts especially—for the risk came in an especial degree from them—to be more cautious in the way they drove about the streets. At the same time he was bound to say that a great amount of carelessness existed, not simply amongst the drivers, but amongst the foot passengers crossing the streets.

Professional Courtesies.

A Dr. Samuel H. Campbell, of Portrush, enjoys the notoriety of having last week sued at law a medical brother, an Indian officer, for an attendance on his wife. The prosecutor alleged that he paid forty visits, for which he charged 5*s.* each, and this number the defendant declared to be "preposterous." The chairman, after expressing his surprise—no doubt he meant disgust—at the spectacle of one medical man suing another for an attendance on his wife, reserved his decision.

Whether the law may or may not give Dr. Campbell his five shillings a visit is little matter. The *lex non scripta*, which every respectable member of the profession holds to be more binding than the statute, declares his demand, under any circumstances, infinitely more discreditable to him than to the defendant. The institution which enrols Dr. Campbell amongst its distinguished *alumni* is the University of Glasgow ; and we doubt not it will feel honoured in possessing him when its graduates read the newspaper report of his prosecution of a medical brother for the care of a sick wife.

As a twin case to this we quote a paragraph from the *Rotherham Advertiser*, which states that the workhouse medical officer of a neighbouring district having applied to his guardians for an increase of salary, his pittance being apparently a paltry sum of £20 (twopence per visit), a rival practitioner volunteered to take the office without an advance of salary.

Perhaps the prosecutor of Dr. Doake might avail himself of this information and put in a bidding for the office without any salary at all.

Adulteration Prosecutions in Dublin.

The report of the sanitary inspector of the Public Health Committee, Dublin, for 1875, shows that thirty-two prosecutions were successful for adulteration of milk, coffee, mustard, &c., resulting in fines to the amount of £112, with £57 costs.

Thirty-two prosecutions in a city having a population of 246,326 persons is just one prosecution to every 8000 persons, or nearly one to each parish in the city. Surely the Public Health Committee cannot now be charged with languor or want of vigilance, for they actually detect sophistication in about half an ounce out of each hundred tons of adulterated food and drugs sold in the city of Dublin. What a blessing is representative government, especially when the balance is held by such lynx-eyed, implacable, and incorruptible judges as the Public Health Committee of the Dublin Corporation !

The Sanitary Condition of India.

Our readers have been from time to time kept *au courant* by our correspondent in India with the medical and sanitary affairs of that country. On Friday evening a paper was read before the Society of Arts by Capt. Dalton, C.B., confirming in many particulars the views which have appeared in our columns. He remarked that consequent on the efforts of the Royal Commission on the Sanitary State of the Indian Army, the British troops had been provided with barracks of unsurpassed accommodation, with the most approved food, and with agreeable occupations. As yet, however, there had only been established sanitary oases for British troops in the midst of insanitary deserts. The sanitary improvements of the Indian army had brought into notice the grievously defective sanitary state of the native towns and villages in close proximity to the cantonments. The surface of the ground in and around the villages and towns was covered with filth of every kind. The water supply was derived from streams, wells, and tanks. The streams were used as receptacles for excrement, the tanks for ablution and bathing; and wells were found to contain impurity derived from the foul subsoil and fouler adjacent surface. The sanitary reports on India all concurred in showing that the neglect of sanitary laws had been universal over the whole country. At the root of the whole question of the sanitary improvement of India lay the question of an accurate registration of births and deaths, and a correct census of the population. Without correct information regarding the number there could be no basis for conclusion as to the health or prosperity of a people, and the determination of a death-rate was essential for showing the points where the efforts of the sanitary reformer were most required. The returns of deaths, based on the system of registration introduced about 1864, were quite worthless; and the returns of births were also imperfect. Registration in rural circles was very incomplete. It was said that any attempt to introduce a system of compulsory registration of births and deaths in the Punjab would, under present circumstances, be unpopular, and in the absence of trustworthy agency for the enforcement of the law, lead to much corruption. The people, however, were becoming alive to the advantages of registration. A vast number of births and deaths were still concealed, or never reported, in all parts of India; and indeed infanticide of female children prevailed very largely. That crime could only be put down by enforcing the accurate registratation of all domestic events in suspected families, and frequent inspection of female infants. Vaccination had now been introduced by the Indian Government, and each year produced better results in reducing the number of deaths from small-pox. The most prominent feature in the returns of deaths was the wide-spread prevalence of fever, and out of 2,705,637 deaths registered in 1874, 1,644,342 were from fever. Evidence showed that the high fever death-rate was due to stagnating water in the soil. In conclusion he observed that the task which the Government of India had set itself to perform was gigantic; and although the sanitary progress which had been made in the country during the last ten years had no parallel in the history of the world, yet each step of forward progress only showed more clearly the vast amount of work which remained to be done.

Conspiring to Murder.

A case of a most singular character involving questions of great importance to the profession and the public occupied the attention of the magistrate at Bow Street on Friday last.

A medical student and a young married woman were charged with conspiring to murder some person at present unknown, when the following extraordinary evidence was produced.

An advertisement was inserted in the *Daily Telegraph* February 18th 1876, addressed "To medical men in need of money, or students well up in chemistry or anatomy. A gentleman engaged in an interesting experiment is willing to give liberal remuneration for professional assistance. Q. W., Post-office, Junction-road, Kentish-town, N.W."

The male prisoner appears to have replied to the advertisement offering his services, and to have received two guineas for his advice, and subsequently to have written a second letter, which not having been called for, was sent in the ordinary course to the dead letter office, where its contents were read and the matter placed in the hands of the police. The police traced the writer, who handed to the officer the following letter from the female prisoner. We give both letters in full as read, abstaining from any comments upon the case, as it is still under examination.

59, Euston-road, N.W., Wednesday.

My dear Sir,—It occurs to me I may not have very clearly explained my suggested *modus operandi*. One thinks of many things pertinent after closing the letter for post. Referring to your note of the 20th, I must say there is risk of discovery, with whatever mode of death. For the registrar requires notice of "cause of death" from medical attendant—should this not be forthcoming, an inquest, and in all cases of sudden death an inquest. If a person die under unnatural or suspiciuus conditions, and the matter hushed up, and no inquest—this implies the distinct connivance of friends. But you desire to have your friend or friends ignorant of any premeditated design, and no doctor called in attendance. Under these circumstances there must ensue a coroner,s inquiry. My plan is this. Sudden death allowed, or apparently suspicious death acknowledged, still a favourable verdict may be returned which in no way can invalidate a will made antecedent to death—probably many weeks. The peculiarity of my suggestion is that although the actual cause of death is found out, and that a narcotic, yet the verdict will be the most lenient, viz.—"by misadventure," or as it is phrased sometimes more specifically, "The deceased was in the habit of taken chloral, and died from an overdose incautiously administered by himself." I can arrange details to "square" with this, and submit them to you at our meeting or on paper. If you like, chloral might be administered to a dog or cat, or you might try yourself an ordinary dose, and be thereby cognisant of the bona fides of the agent. Upon mature consideration, I know of no more feasible method. The cases of the poisoners Prichard and Palmer, both doctors, were ingenious, yet they were detected. They lived before these chloral times. As an anatomist and medical jurist, I altogether frown on any attempt to excite arterial rupture, &c., and am willing to adduce reasons. I write this letter at 52, Brady Street, Bethnal-green, E., where I am since yesterday, doing full duty for Surgeon Mainwaring. We have a surgery here, and I have access to the drugs, bottles, and labels, &c. I return to Euston-road to-night, and will have a supply of the drug. If you adopt my theory, we might arrange to meet, and then take leave of the subject. You can select your own fit time. I would desire this for several reasons:—(a) To get rid of the affair; have it off my mind, which is natural and human. (b) I am expected to be summoned to Liverpool any of these days to meet my bro'-in-law, returning in a sailing vessel from San Francisco. (c.) A cousin of mine en route for Hamburg is coming to 59 Euston-

road, to stay a few days, and if I be not in Liverpool next Tuesday, I want to be at his service.—Expecting a reply, believe me, Sir, in confidence, yours, W. K. V.

February 20, 1876.

Dear Sir,—I make no question you could be of service of to me. The question is, will you? The solatium I offer is £100. The conditions these:—I am tired of my life. I could do a great deal of good to a person I am interested in by leaving the world just now, and one way or another I am resolved to do so, but if possible I should prefer not to wound the feelings of the person who will gain most by my death, by allowing it to be supposed voluntary. Besides, the most merciful verdict of a coroner's jury would be sufficient to invalidate my will. Now, although I have some acquaintance with medicine and chemistry, I know of no drug or combination of drugs which would do this for me without risk of discovery. It is possible you may. It is not absolutely essential that the supposed means should be painless, or even very quick in their results. If some artery could be hurt with any plausible appearance of accident, assistance summoned too late, &c. I am willing to allow time for experiments, have no objection to a personal interview. I will give any assurance of bona fides that may be thought necessary. I only request that this communication be considered strictly private.—Yours faithfully, M. Q.

Address to these initials at the P.O., Junction-road, Kentish-town, N.W.

The West Riding Asylum.

On Tuesday week, a dinner was given at Wakefield, and testimonials presented, to Dr. J. Crichton Browne, who, on being appointed one of the Lord Chancellor's Visitors in Lunacy, has resigned the office of Medical Director of the West Riding Pauper Lunatic Asylum. Lord Houghton was in the chair, and Mr. W. Spencer Stanhope, M.P., and Dr. Heaton, J.P., made the presentations. The testimonials consisted of a coffee tray, claret jug, and cabinet of plate, subscribed for by a body of friends, and of an épergne the cost of which had been defrayed by the medical profession in the West Riding. Mr. Stanhope said it was well known that under the superintendence of Dr. Crichton Browne the West Riding Asylum had risen to position which was second to none in this country. Lord Houghton said he was sure he expressed the undivided feeling of the magistracy and gentry of the county in saying that they much regretted the departure of Dr. Browne from among them. From the time of his first coming Dr. Browne had gone on winning the esteem of Yorkshiremen. He had done it by two processes—one by the faithful exercise of an innate intelligence, and the other by a moral charm, which had never made him assert any undue superiority, and which had made him at once the companion and teacher of all around him. He did not think that even in that great community to which Dr. Browne was going he would remain either unknown or unappreciated. Dr. Browne, in responding, showed that in the history of lunacy it was a remarkable fact that it was the introduction of the scientific conception which had led to the modern and humane treatment of the insane. The lunatic asylums of this country were placed under the management of what he regarded as the very best governing body—a committee of county justices. But the fact still remained that all progress in our asylums had grown out of the scientific conception of lunacy. During the ten years in which he had presided over the West Riding Asylum he had constantly held that in view; and, aided by an able and willing band of colleagues, he had endeavoured to make that institution a scientific centre and school of medicine. He might appeal to the number of patients who had passed through the asylum, restored from insanity to the light of reason, to prove that, in the pursuit of the laws of nature, the laws of kindness had not been forgotten. Dr. Browne is succeeded at the asylum by Dr. H. C. Major.

Pharmacy in Ireland.

The Council of the Irish Pharmaceutical Society has had a meeting last week, when Professor Tichborne introduced the subject of holding evening meetings in connection with the society, remarking that the only advantages of membership were the privilege of voting for members of council, and being eligible for membership of the council. After some discussion, instead of the original motion, he proposed the following:—

"That the council approves of the principle of holding evening meetings in connection with the society for the reading and discussion of papers connected with pharmacy."

The motion was carried unanimously. A number of resolutions conversant with unimportant details in the management of the society were passed. An interesting notice of motion had been placed on the books by Dr. Whittaker, of Belfast, in the following terms:—

"That steps be taken to bring before the notice of the Chief Secretary for Ireland the advisability of having the Pharmacy Act (Ireland) amended, so as to give power to the council of the Pharmaceutical Society to register as druggists all at present in the business, and to confirm them in the rights they at present enjoy: also to make arrangements for the future as regards the qualification of those who may wish to keep open shop for the sale of poisons and poisonous drugs, without the privilege of compounding the prescriptions of members of the medical profession, &c."

As Dr. Whittaker was not present the motion was postponed. The examination for the licence of the Pharmaceutical Society of Ireland was held on the 5th inst. when 21 candidates offered themselves, of whom seven were "plucked." The next examination will be held on this day week.

How Fever is Spread.

Public attention has been directed to the danger of incautiously spreading fevers and other infectious diseases among the middle and upper classes through the medium of cabs and other public vehicles. An instance of this came before the Canterbury magistrates on Saturday last, when a schoolmaster was heavily fined for sending two boys home from school by railway, they having at the time scarlet fever rash upon them. Another difficulty now presents itself, namely, the isolation of patients. In the case of scarlet fever, for instance, it is pointed out that a long quarantine of about six weeks is absolutely necessary. A letter which appeared in a morning contemporary directs attention to the Fever Hospital, where private rooms can be had for both males and females. These rooms are very lofty, well ventilated, and fitted up in every way for fever requirements. Here is complete isolation, while the patient has the great advantage of the attendance of the visiting physicians, resident medical

officer, and the care of trained nurses. Every requisite in cases of fever is afforded him, and he is kept in the hospital until all traces of infection have disappeared. The charge, including everything, is only £3 3s. per week. It can hardly be denied that this possibility of isolation is an immense boon to the friends and neighbours of the patient, to say nothing of its importance as a means of checking the spread of fever and preventing epidemics. Besides these private rooms are many large wards. Into these are admitted domestic servants, *employés*, and others; the fee for the whole time the patient is in the hospital being only £2 2s. (about one-third of the sum spent on him during his illness), besides a large number of non-pauper poor, to whom no charge whatever is made. This is a very great tax on the resources of this badly-supported institution, and to meet the expenditure thus caused some of its funds have annually to be sold out. It is feared that if more funds are not forthcoming the usefulness of the hospital (which is almost entirely supported by voluntary contributions) will be eventually seriously impaired, and this we venture to submit would be a most serious loss to London. London with all its wealth can surely afford to support such a valuable institution as this, which has done and still does such immense service, not only by preventing the spread of epidemics by its system of isolation, but also by relieving the sufferings and hastening the recovery of those attacked by fever.

Irish Union Drug Contracts.

We find the following in an Irish provincial paper :—

"All the tenders having been examined, the tender of Messrs. A. B. and Co. was accepted, it having been made much lower than B. C. and Co., the only other which was received."

This is the old story. The bucolics who act as Poor-law guardians, and whom the law sagely makes the judges of drugs and their cost, escape from the muddle by accepting the lowest tender. Those who are initiated in such matters are aware that such tender may not improbably be, not only the worst, but also the dearest, and thus the paupers may be starved of their physic, and the ratepayers at the same time mulcted of their money through the agency of the present law. The continuance of the present iniquitous system of Irish drug contracts is the greatest blot upon the executive character of the Local Government Board. We earnestly recommend it to the attention of the new Medical Commissioner.

Salicylic Acid in Acute Rheumatism.

Salicylic acid appears to be gradually rising in the estimation of the profession in America as well as Europe. Professors Traube and Stricker have recently reported most favourable results in several cases of acute rheumatism, and Drs. Putnam and Warren have tried the drug in the United States with equally satisfactory results. The latter reports a case in the last number of the *Boston Medical Journal*, the patient being a young man about twenty years of age, a breaksman on the railway. Having treated him with the usual remedies, all of which failed, except in giving relief for a short period, the pain returning with increased virulence, Dr. Warren was induced to try salicylic acid. He found his patient with the pulse at 120; very nervous and fretful; skin hot and dry; tongue coated; urine high-coloured. Salicylic acid was given, seven grains in wafers every two or three hours, with no other treatment whatever. This treatment was commenced sometime in the forenoon. After the first few doses marked improvement was noticed, and, after the ninth dose, sixty-three grains in all, the patient was decidedly better. The skin became moist, the tongue nearly clean, the pulse 80. The inflammation had gone from the foot and knees; the patient's spirits were good; there was no appearance of inflammation in other parts of the body, as before, and he remarked that he felt well enough to get up and go to work. The same treatment was followed, and the patient rapidly recovered.

The Public Health of Ireland.

The Irish Registrar-General has just issued his report of the health of Dublin and the principal towns of Ireland for the quarter ending on the 1st of April.

Deaths.—The deaths registered in the Dublin district amounted to 2,695, afforded an annual ratio of 34 in every 1,000. The average number in the first quarter of the previous ten years was 2,498.

The ratio of deaths north of the Liffey was 37, and south of the river 36 in every 1,000. In the suburbs of Rathmines, Donnybrook, Blackrock, and Kingstown the annual death-rate was 27 in every 1,000.

The deaths registered in Belfast represent an annual ratio of 28 in every 1,000, in Cork 34, in Limerick 38, in Londonderry 21, in Waterford 25, in Galway 26, and in Sligo 21.

The ratio of deaths registered in London was 25, in Glasgow 30, and in Edinburgh 25 in every 1,000.

The ratio of deaths in Dublin from zymotic diseases was 16.3 per cent. of all the deaths, and 5.6 in every 1,000 This number is 14 over that for the preceding quarter, and 117 in excess of the number registered in the first quarter of last year. The deaths from the seven principal diseases of this class represent a rate of 4 per 1,000.

The increase in the mortality from zymotic diseases is owing to the prevalence of whooping-cough, from which disease 112 deaths, or 4.2 per cent. of the total deaths from all causes resulted.

Fever caused 64 deaths—viz., typhus 13, typhoid or enteric 35, and simple continued fever 16. The deaths from fever are 4 less than in the preceding quarter, and 13 under the number in the March quarter of 1875.

64 deaths resulted from scarlet fever, 42 from measles, 25 from croup, 3 from diphtheria, 5 from influenza, 33 from diarrhœa, &c.

192 deaths, or 7.1 per cent. of the total, were ascribed to convulsions.

Bronchitis caused 597 deaths, or 22.2 per cent. of the total. This mortality, although large, is less than that from the same cause in the first quarter of last year, when 686 deaths from bronchitis were registered. 83 deaths were referred to pneumonia, 9 to pleurisy, 6 to asthma, and 61 to lung disease unspecified.

Apoplexy was assigned as the cause of death in 21 instances, paralysis in 49, inflammation of the brain and its

membranes in 16, epilepsy in 9, insanity in 5, chorea in 1, and brain disease unspecified in 27.

Heart disease proved fatal in 108 instances, aneurism in 7, pericarditis in 2, liver disease in 24, hepatitis and jaundice each in 3, Bright's disease in 9, cystitis in 4, ischuria in 2, and kidney disease unspecified in 25.

293 deaths resulted from phthisis, 41 from mesenteric disease, 66 from hydrocephalus, 10 from scrofula, and 22 from cancer.

Provincial Towns.—The deaths from the seven principal zymotic diseases in Belfast, which numbered 196 in the preceding quarter, and 343 in the March quarter of 1875, fell to 94 last quarter—viz., scarlet fever 28 (against 62 in the preceding quarter), whooping-cough 20, diarrhœa 19, fever 16, diphtheria 8, and measles 3. These deaths represent an annual death-rate of 2.1 per 1,000. There were no deaths from small-pox in this or any other of the towns included in this return.

96 deaths, equal to an annual rate of 4.2 per 1,000, were caused by the principal zymotic diseases in Cork. Of these deaths 30 were from measles, 23 from fever, 17 from whooping-cough, 13 from diarrhœa, 12 from scarlet fever, and 1 from diphtheria.

In Limerick there were 51 deaths from the seven zymotic diseases, of which number as many as 33 were from whooping-cough; 10 were from diarrhœa, 6 from fever, and 2 from scarlet fever, the total affording an annual rate of 4.6 per 1,000.

18 deaths from scarlet fever (against 41 in the preceding quarter), 5 from measles, 3 each from whooping-cough and diarrhœa, 2 from diphtheria, and 1 from fever, were registered in Londonderry, the annual rate represented thereby being 4.1 per 1,000.

A LARGER proportion of candidates than usual passed the examination for the M.R.C.S. Eng. last week; out of 59 all were successful but 13.

MESSRS. JAMES HOUGH, of Cambridge, John Leigh, of Pontypridd, and William Pollard, of Torquay, have been elected Fellows of the Royal College of Surgeons of England.

SMALL-POX is still very prevalent in Manchester and Salford; thirteen more fatal cases occurred last week, raising the total of the three months to one hundred and thirty-two.

THE Professors of the School of the Dublin College of Surgeons have instituted two exhibitions—a Junior of £15, and a Senior of £25—to be competed for at the end of each winter session.

BOTH the birth and death rates were much under the average last week in London, a matter which does not often occur in such noticeable proportions. The birth-rate was 265, and the death-rate 160 under the average of the last 10 years.

Two hundred and fifty-six deaths were recorded in the large public institutions of London last week, being 18 per cent. of the total deaths; of these only two occurred in lunatic asylums, showing the excellence of their medical supervision.

FROM an answer given to Colonel Leigh by Viscount Sandon in the House of Commons last month, it appears that some legislation in respect to regulating the sale of patent medicines is at present being considered by the Privy Council.

DR. H. CHARLTON BASTIAN, F.R.S., has been appointed Examiner in Medicine; Dr. William Stokes, Surgery; Dr. J. Guinness Beatty, Midwifery; Professor Pye, M.D., Materia Medica; and Dr. William Stoker, Examiner in Medical Jurisprudence, in the Queen's University of Ireland.

GEORGE F. DUFFEY, Esq., M.D., 30, Fitzwilliam Place, Fellow of the King and Queen's College of Physicians, Ireland, and Lecturer in Materia Medica in the Carmichael School of Medicine, has been appointed Physician to Mercer's Hospital, Dublin. Dr. Duffey was the editor of the *Irish Hospital Gazette*, and is Secretary of the Medical Society of Dublin.

MUCH anxiety has been caused in Dublin during the last two months by reports as to the high local death rate, which was generally attributed to the severe weather causing pulmonary diseases. Dr. Cameron, the city analyst, has now published a paper in which he shows that the death rate of Dublin proper, with its population of 246,000, is, when public institutions are excluded, little over 1 9 per 1000.

THIS fastidious nineteenth century, says the *Chemist and Druggist*, seems never to tire itself with the invention of new luxuries. We read that a society of rat-eaters has been formed at Gembloux, in Belgium; the members meet once a week, and the proceedings are wound up by a grand banquet, in which preparations of that delicious animal hold a prominent position. But we have yet to record the climax, or shall we say the *cimex*. From homœopathic literature we learn that Dr. Wahle, of Rome, and Dr. Berridge, of London, have been making "provings" with triturations and dilutions of our intimate friend the bed-bug, as a remedy in cases of intermittent fever.

AT the last meeting of the Council of the Medical Defence Association a handbill, *said to have been issued by a member of the Council of the British Medical Association who practises homœopathy in the East End*, was submitted to the Council, but it was decided that the matter was one which scarcely came within the province of the Defence Association, and the Secretary was requested to send a copy of the handbill to the Secretary of the Council of the British Medical Association.

We ask the attention of the members of the British Medical Association to the words which we have italicised, and await an explanation. We can hardly conceive it possible that any person who has received the honour of a seat on the Council of the Association will be found to answer to such a description. If it be so, the sooner the Association expurgates its Council the better.

LEGISLATION FOR THE HELPLESS.

(THE BLIND.)

Some few weeks since we took occasion to direct attention to the several legislative enactments passed in favour of the afflicted classes of the community at the same time we pointed out that those charged with their administration had taken no care to comply with the beneficial provisions of these Acts. We now propose to inquire what has been effected by charitable efforts for that afflicted class—the Blind. Up to the present time the several institutions for the blind have been inaugurated and maintained by private charity, and entirely apart from State aid; in many instances before legislation commenced. It is quite evident that existing legislation has received no attention from managers of charities, or they would not allow their institutions to be filled by such of the afflicted for whom ample legal provision has been made. It is tolerably certain also that subscribers cannot be aware of the fact that nearly two-thirds of the donations poured into the coffers of charitably supported institutions merely goes towards relieving guardians of the poor from an obligation laid upon them by the Legislature. It cannot be doubted then that in attempting to deal with the ever increasing numbers of the afflicted classes, benevolent persons are attempting a task wholly beyond the powers of voluntary efforts, and to the extent of their failure, they are actually injuring the cause to which their benevolence is directed. The Legislature has positively determined that henceforth there shall be no legal exclusion of the blind from any of the benefits of education. Why, then, should charity stand in the way, and why should only a small percentage of blind children be receiving the benefits of which they stand more in need than those blessed with sight? It is acknowledged that the education of the blind is more expensive; nevertheless, no institution has thought of applying for the Government grants, freely offered, and which could be had for the asking.

A systematic course of education is essential for the blind, and from a long intercourse with them we may say, without fear of contradiction, that it is chiefly to the system of education pursued in this country that the blind attribute the sufferings which almost invariably attend their steps through life, and unless the benevolent supporters of existing institutions can be induced to see that isolation and a denial of most of the rights of social beings are fundamental errors in their present superficial and fragmentary mode of education, the best interests of the blind, whose intelligence is in nowise inferior to the average of human beings, must be utterly sacrificed.

Our Continental neighbours deserve credit for the success which has attended efforts made some years ago to improve the condition of the blind. In 1836 the Belgian Chamber of Deputies determined to collect together the blind, deaf and dumb, and educate them at the cost of the State. In this country, although legislation in favour of these classes commenced four years earlier, in 1832, nothing whatever was done until the year 1868, when the Metropolitan Poor Act came into force. Soon after some attempt was made to improve the neglected condition of the idiot and insane in workhouses, but nothing was done for the blind. Under this Act the Asylums Board was established, and it is quite within the powers of the Local Government Board to hand over all the blind and deaf and dumb, children and adults to this Board, and in the case of the children belonging to these classes, it is particularly provided that they do not receive relief as paupers. There is also the Act of 1870, known as the "General Education Act," a comprehensive Act, passed for the purpose of securing the general education of children, including all classes of the afflicted. The School Board may establish industrial schools, or send these blind children to existing industrial schools, and pay the cost of their education out of a common fund. A somewhat unsuccessful effort has been made by the School Board of London to bring blind children into their schools.

The Act is, however, capable of further extension, or could be rendered more serviceable to the afflicted poor by the Act 30, 31 Vic., 1867, whereby the guardians can, if they think proper, provide for the maintenance and education of any child or adult pauper, being blind or deaf and dumb, in any hospital or institution established for the reception of persons suffering from such infirmities. Legislative enactments are, however, disregarded, for there are at the present moment 493 blind immured in metropolitan workhouses, and there they must remain under the most neglected and forsaken conditions. These should at least be removed to some separate institution, where they would have suitable care and treatment under proper supervision.

Not one of the institutions professedly established to educate the blind fulfils its object. On the contrary, the system of voting and canvassing so generally adopted, with all its attendant evils, effectually mars the efforts of the benevolent, and paralyses the laudable intentions of the Legislature, by treating all candidates for admission as paupers.

(To be continued.)

Correspondence.

RICHMOND WATER SUPPLY.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—In your paper of the 5th inst., remarking upon the water supply of Richmond, you state that the Southwark and Vauxhall Water Company have for several years supplied unfiltered water to the town, and that the Vice-Chancellor Malins, in giving judgment on the recent motion for an injunction, said,: "It was not to be supposed that because Richmond had tolerated water abounding in living organisms for ten years that they should be for ever debarred and stopped from saying that they would rest quiet no longer."

Both these statements are untrue, and without foundation, and it is greatly to be regretted that you should have allowed such serious misrepresentations to appear in your columns.

We have to request that you will insert this letter in your next issue.

Your obedient servants,

Bircham & Co.

60 Threadneedle Street, London, 14th April, 1876.

[We do not profess to have confined ourselves to the exact words of the Vice-Chancellor, but in justification it must be stated that during the inquiry which took place at Richmond last autumn before the Local Government Board Commissioner, one of the chief complaints against the Southwark and Vauxhall Water Company was that for a considerable period the Company used a double set of pipes, one of which supplied the town with unfiltered water. This was stated as a fact, and fully accounted for the presence of the live fish which were taken from the cisterns of the inhabitants. That the water of the Company does still abound in living organisms is seen on reference to the monthly reports of Professor Frankland.—Ed. M. P. & C.]

Obituary.

SIR W. WILDE.

The profession in Ireland, which has been so unfortunate within the last decade as to lose three of its most distinguished members, who were the ornaments of the last half century, has sustained a further loss in the death of Sir William Wilde, who succumbed to an attack of acute bronchitis on this day week. Sir William Wilde was essentially a self-made man. He brought to the practice of his profession neither influence nor fortune, but depended for the success which he achieved upon the brilliancy of his intellectual qualities as much or more than upon his professional opportunities. He was the son of Dr. Thomas Wilde, a general practitioner in the town of Castlerea,

where he was born in the year 1815, and spent his schoolboy-days at the Banagher Royal School, and afterwards at the Bishop's School at Elphin. His first entry into medicine was as the apprentice of Abraham Colles, and as Resident at Steeven's Hospital, and afterwards as dresser, or rather Clinical Clerk, to Dr. Evory Kennedy. His connection with Steeven's Hospital, and the qualities which he had there developed, bore to young Wilde substantial fruit; for after he had received his qualification as Surgeon from the College of Surgeons in 1837, he was recommended by Marsh and Graves to the attendance on an invalid in a health expedition to the Mediterranean. This voyage laid the seeds of literary efforts on his part with which his earliest professional name is associated, which made evident his peculiar qualities as a *littérateur*, and at once established him as a man of versatility of intellect and originality of thought. His voyage to the south of Europe gave him an opportunity of seeing Madeira, the north of Africa, and the Archipelago, and of publishing on his return home most interesting "narratives" of his expedition, which was read in literary circles and thought highly of as the maiden effort of an aspiring author. But all this was not strictly *ad rem* as regards the medical future of his life, and it became necessary for him on his return home to seek a special education on the Continent, and, selecting Vienna for his home, he applied himself to study. The opportunities which he there enjoyed of seeing the inner life of the Austrian capital were not lost upon Wilde, for he was a man upon whom the chance of seeing and hearing was never thrown away, and his experience in Vienna bore its fruit in his *brochure* on the literary, medical, and scientific institutions of Austria, which made known for the first time his special interest and capacity for statistics, a quality which brought him in after life much of his public repute. Sir William Wilde's first effort as an ophthalmic and aural surgeon was in the year 1841, when he established his relation to the sick poor by an Eye and Ear Dispensary in South Frederick Lane. From this uncongenial locality he moved his institution to Mark Street in, 1844, and again in 1850 to the present site of St. Mark's Hospital, in Lincoln Place, which since that day has been better known as Wilde's Hospital, and has been familiar for its surgical character to both the public and the profession in Ireland. Thence grew his personal celebrity in his own speciality, which brought him not only the confidence of the community, but a lucrative return for his labours, and which he has enjoyed until the day of his death.

We have said that Sir William Wilde's public reputation rested as much upon his versatility of genius as his talents as a surgeon, and his qualities as a statictician obtained for him at a comparatively early age the recognition of the Government of the day. The censuses of Ireland of 1851, 1861, and 1871 in their medical aspects were confided to his care, and that confidence was amply repaid by the energy and talent which their production manifested. The task of classification and tabulation of the diseases of Ireland of that day was rendered the more interesting and the more difficult in consequence of the fever epidemics which immediately preceded 1851, and it was universally admitted that the questions which thus arose were treated with great ability and comprehensiveness, and that the statistics at his command were presented by Sir William Wilde to the public in a very valuable form. The success which his ability thus achieved gained for him a rare honour, when he received knighthood from the Sword of the Earl of Carlisle, and the last census fully justified by the careful compilation of its medical department the high opinion of Wilde's qualities which the Government thus evinced.

We are prohibited by the demands on our space from detailing Sir William Wilde's contributions to literature and to his profession, which are already familiar to all our Irish readers, and which, one and all, indicated an original turn of mind and a peculiarity of expression quite in keeping with their author's character. Many of these works were devoted to archæology, of which science he was a devoted student, and the Royal Irish Academy bears record of his industry and intelligence in the pursuit of antiquarian research, being indebted to him for those descriptive catalogues of the valuable historic contents of its museum.

Sir William Wilde may be truthfully said to have been a remarkable man—remarkable for his originality, his versatility, and his eccentricity. He had no quality in common with the common-place money-grubbing doctor; cared less for the accumulation of fees than for the enlargement of the bounds of science; was nothing of a diplomatist and less of a sycophant; but much of a lover of science. These honours which he enjoyed he won by none of the "booing and booing" which Sir Pertinax Macsycoplant advises as the royal road to distinction, but, on the contrary, by brilliant personal qualities, which perhaps shone with the greater lustre from being placed in contrast with an eccentric *brusquerie* of manner.

As a surgeon, an antiquarian, a public man, and a social genius, Wilde will dwell in the memories of the profession.

Medical News.

Royal College of Surgeons of England.—The following gentlemen were admitted Members of the College at meetings of the Court of Examiners on the 18th and 19th inst.:—

Atkinson, Richard, Carlisle.
Barrs, Alfred G., M.D., Leicester.
Batterbury, Richard L., M.B., Haverstock Hill.
Best, George Payne, Brompton.
Bowen, Edward, Southsea.
Bradley, Robert, Shepherd's Bush.
Bradshaw, James D., Bowdon, Cheshire.
Bruce, Robert, L.S.A., Old Street.
Bull, James W., Chislehurst.
Burnham, George H., M.B,, Peterborough, Canada.
Cane, Howard, Queen Square.
Carter, Howard B., Watling Street.
Chavasse, Thomas F., Birmingham.
Clarke, Robert H., Tavistock, Devon.
Davies, Francis J., Newport, Monmouthshire.
Eccles, Arthur S., Plymouth.
Ellis, Joseph W., L.S.A., Willingham, Cambs.
Fisher, Thomas, L.S.A., St. Michael's-on-Wye.
Foster, Henry, York.
Frankish, William J., Kirmington, Lincoln.
Fraser, Donald B., M.D., Ontario, Canada.
Griffith, David C. B., Surbiton.
Hodson, Robert D., Bath.
Honeywill, Silas, Lee, Kent.
Hunt, Joseph W., Mildmay Park.
Hyne, Frederick A., L.S.A., South Square, Gray's Inn.
Judson, Thomas R., Forest Hill.
Kay-Shuttleworth, Lionel E., Cromwell Road.
Mackay, James J., Fermoy, co. Cork.
Merriman, John W. C., Kensington Square.
Murphy, Henry Howard, L.R.C.P., Brompton.
Parker, Arthur F., Clifton, Bristol.
Pearse, Joshua S., L.R.C.P., Plymouth.
Pinnell, Thomas M., St. John's Wood Terrace.
Scott, John H., M.B., Edinburgh.
Sloman, Herbert, L.R.C.P., Farnham, Surrey.
Southam, Frederick A., Manchester.
Taylor, James, L.S.A., Bristol.
Thompson, Arthur H., Gomersal, Yorkshire.
Tiraad, Nestor J. C., Curzon Street.
Tuke, George M., Sittingbourne, Kent.
Verrall, Thomas J., Brighton.
Walker, George, Wimbledon.
Warren, Charles E. H., Edinburgh.
Wilkins, Robert B., Newport, Isle of Wight.
Wilson, Arthur Huelin, L.R.C.P., St. George's Hosp.

Vital Statistics.—From the Registrar-General's return we learn that during last week 5,053 births and 3,639 deaths were registered in London, and twenty-two other large towns of the United Kingdom. The mortality from all causes was at the average rate of 26 deaths annually in every 1000 persons living. The annual death-rate was 21 per 1000 in Edinburgh, 22 in

London, 20 in Glasgow, and 23 in Dublin. Showing in each of these large cities a considerable diminution of the death rate. The annual rates of mortality during the same period in the other large towns were—Norwich 19, Hull 18, Leicester 21, Portsmouth 16, Newcastle-upon-Tyne 26, Birmingham 23, Brighton 16, Leeds 25, Wolverhampton 24, Bradford 27, Sheffield 25, Plymouth 20, Bristol 23, Oldham 29, Manchester 32, Salford 28, Nottingham 31, Sunderland 24, and Liverpool 28. The annual death-rate from the seven principal zymotic diseases averaged 3·4 per 1000 in these towns, and ranged from 0·0 and 1·5 in Norwich and Hull, to 6·0 and 6·5 in Liverpool and Brlstol. Measles and whooping-cough show fatal prevalence in Liverpool, and the deaths referred to scarlet fever were again excessive in Bristol. Thirteen more fatal cases of small-pox were recorded in Manchester and Salford. In London, the 1,434 deaths included 4 from small-pox, 44 from measles, 35 from scarlet fever, 6 from diphtheria, 83 from whooping-cough, 18 from different forms of fever, and 16 from diarrhœa; thus to the seven principal diseases of the zymotic class 206 deaths were referred, against 234 and 225 in the two preceding weeks. The 18 deaths referred to fever were no less than 20 below the corrected average; one was certified as typhus, 13 as enteric or typhoid, and 4 as simple continued fever. The deaths referred to diseases of the respiratory organs, which in the two previous weeks had been 415 and 385, further declined last week to 317, of which 192 resulted from bronchitis and 97 from pneumonia.

Cambridge University Reform.—A memorial, signed by a number of professors, fellows, &c., has been forwarded to the Premier, urging the following reforms in reference to Cambridge University:—No fellowship should be tenable for life, except when the original tenure is extended in consideration of services rendered to education, learning, or sciences actively and directly in connection with the university or the colleges. A permanent professional career should be as far as possible secured to resident educators and students, whether married or not. Provision should be made for the association of the colleges, or some of them, for educational purposes, so as to secure more efficient teaching, and to allow to the teachers more leisure for private study. The pecuniary and other relations subsisting between the university and the colleges should be revised, and, if necessary, a representative board of university finance should be organised.

NOTICES TO CORRESPONDENTS.

☞ Correspondents requiring a reply in this column are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

Reading Cases.—Cloth board cases, gilt-lettered, containing 26 strings for holding each volume of the Medical Press and Circular, can now be had at either office of this Journal, price 2s. 6d. The postal regulations not allowing the Journal to be stitched, these cases will be found very useful to keep each weekly number intact, clean, and flat, after it has passed through the post.

Dr. Gongosa.—We believe there are very few medical journals published in Spain; we know of one only—*El Pabellon Medico*—a weekly illustrated journal of considerable merit, both in appearance and contents. We presume you will have no difficulty in getting this journal during your stay in this country; the publishing office is in Madrid.

Dr. H. C. M. will please accept our best thanks.

An Interested One.—As yet we have received no definite intelligence. We will communicate with you by letter at the proper time.

A Student.—You will find "Griffiths' Notes on the Pharmacopœia" and "Scoresby-Jackson's Materia Medica" answer your requirements for the examination.

Dr. Dickinson is thanked for his letter.

A Tax on Medicine.—We understand that our American *confrères* are about to have imposed upon them a personal tax of twenty-five dollars a year for the privilege of practising medicine in certain districts. The reason for this—to our way of thinking—unwarrantable proceeding is not stated.

Dr. Andrew Clark, who was in frequent attendance upon the late Lord Lyttleton prior to his melancholy suicide, wrote yesterday to the *Standard* to correct a misinterpretation of the evidence he gave at the inquest, to which that paper had given publicity. Dr. Clark, for the sake of truth, and of the family of the deceased nobleman, naturally objected to the misconstruction placed upon his words; and having met Lord Lyttleton upon one or two occasions, we are able to add our testimony to that of Dr. Clark, that "a healthier, happier, busier, or more useful life than Lord Lyttleton's could not be. In his method, in his capacity for work, in his management of business, in his discussion of all the stirring questions of the time, in the exercise of his rare scholarship, in his keen sense of humour, there was neither any lack of his accustomed versatility and power nor any vestige of those attacks which at long intervals and for short seasons only had darkened the general sunshine of his lordship's life."

Letters from Dr. Luther and "An Unendowed Surgeon" are unavoidably held over till our next.

Mr. Walter Rivington will read a paper this evening, at the Hunterian Society, "On a Case of Partial Rupture of the Popliteal Artery and Complete Rupture of the Popliteal Vein, treated successfully by Primary Amputation of the Thigh."

Clinical Society of London.—The following is the programme for Friday evening, at 8½ p.m.:—Mr. Spencer Watson, "On Two Cases of Glaucoma treated by Subconjunctival Sclerotomy" (the Patients will be exhibited).—Dr. Buzzard: "A Railway Case: Cerebro-spinal Concussion with Glycosuria."—Dr. Greenhow: "A Case of Patent Ductus Arteriosus, attended by a Thrill and Murmur; Death from Phthisis."

Communications, Enclosures, &c., have been received from—Dr. W. H. Day, London. Dr. Herbert Major, West Riding Lunatic Asylum. Dr. Carpenter, Croydon. Dr. Gongosa. An Interested One. A Student. Dr. H. C. M. Dr. Davidson, Chester Lunatic Asylum. Dr. Myrtle, Harrogate. Mr. Waren Tay, London. Dr. Wilson, Glasgow. Mr. Redmayne, Manchester. Mr. J. L. Milton, London. Mr. R. Summers, Haverfordwest. Dr. Fort, Paris. Mr. W. Berry, Holmfirth, Yorks. Mr. Topham, London. Dr. Abrath, Sunderland. Dr. Balmanno Squire, London. Mr. Bircham, London. Dr. Langley, London. Dr. James, Kensington. Dr. G. M. Dickinson, Paulton, Rugby. The Registrar-General. Dr. Gillespie, Montebello. Mr. Brennen, Royal College of Surgeons of Ireland. VACANCIES.

Birmingham.—Resident Assistant Workhouse Medical Officer. Salary, £150 per annum. Applications to be addressed "The Guardians of the Poor of Birmingham.

Wolverhampton General Hospital.—House-Surgeon. Salary, £100, with board, &c. Also an Assistant House Surgeon. Board and lodgings, but no salary. Applications to the Chairman of the Medical Committee.

West Riding Asylum, Wakefield.—Clinical Clerk. Board and lodging, but no salary. Applications to Dr. Herbert Major.

Liverpool Southern Hospital.—A Third House Surgeon. Salary, 60 guineas, with board, &c. Testimonials to the Chairman of the Medical Board.

Liverpool Dispensaries.—Resident Assistant House Surgeon. Salary, £108. Applications to the Secretary.

Leicester Infirmary.—House-Surgeon and Apothecary. Salary commencing at £120, with board, &c. Testimonials, &c., to the Secretary.

Tiverton Union District.—Medical Officer. Salary, £35. There is also attached to the office a fee of £100 per annum, which is paid by the owner of a neighbouring mill for attendance on the work-people. Address the Clerk of the Union.

Guisborough Union.—Medical Officer of Health. Salary, £400. Applications to the Clerk.

Northampton General Infirmary.—Dispenser. Salary, £125. Applications to the Secretary.

APPOINTMENTS.

Barton, J. K., L.R.C.P.I., M.R.C.S.E., Ophthalmic House-Surgeon to St Bartholomew's Hospital.

Bradley, S. M., F.R.C.S., a Surgeon to the Royal Infirmary, Manchester.

Browne, D. J., L.K.Q.C.P.I. & L.M., L.R.C.S.I., Medical Officer to the Workhouse and Fever Hospital of the Londonderry Union.

Chambers, T. S., L.R.C.P.Ed., L.R.C.S.Ed., Medical Officer for the Raynham District of the Walsingham Union, Norfolk.

Collyns, R. T. P., Resident Medical Officer to Atkinson Morley's Hospital, Wimbledon.

Currie, A. S., M.B., M.R.C.S.E., Resident Medical Officer to the Birmingham and Midland Free Hospital for Sick Children.

Births.

Gillespie.—On the 11th inst., at 3 Montebello Terrace, Bray, the wife of M. J. Gillespie, M.D., B.A., of a son.

Marriages.

Denton—Paradise.—On the 18th inst., at St. Mary's Parish Church, Stamford, Thomas J. Denton, M.D., of Steeple Claydon, Bucks, to Florence Elvena, daughter of John Paradise, J.P., of Stamford.

Fairbank—Sympson.—On the 20th inst., at St. Mary Magdalene's, Lincoln, F. Royston Fairbank, M.D., of Doncaster, to Dora, second daughter of the late T. C. Sympson, Surgeon, of Lincoln, and sister to T. Sympson, F.R.C.S.

Haward - Nicholls.—On the 20th inst., at St. John's Church, Moulsham, Chelmsford, Essex, John Warrington Haward, F.R.C.S., of Montagu Street, London, W., to Amy Cecilia, eldest daughter of James Nicholls, F.R.C.S., of Chelmsford, Essex.

Deaths.

Bateman.—On the 17th April, at East Bridgeford, Notts, Charles Bateman, M.R.C.S.E., &c., aged 45.

Carte.—On the 19th April, at Portland Place, Brighton, John Elliott Carte, C.B., Inspector-General of Hospitals.

Garty.—On the 18th April, at Clyde Terrace, Stockwell Road, Francis Boyle Garty, M.R.C.S.E., aged 59.

IRELAND.—On the 16th April, at Weymouth, John James Ireland, M.R.C.S.E., aged 72.

MACKAY.—On the 12th April, Allan Douglas MacKay, M.B., of Stoney Stratford, aged 45.

MAHOMED.—On the 20th April, at 54 Norfolk Square, Hyde Park, W., Ellen, the wife of F. A. Mahomed, M.D.

RYMER.—On the 11th April, at St. Lawrence, near Ramsgate, James Rymer, M.R.C.S.E., aged 86.

TAYLOR.—On the 8th April, at Whitworth, James Eastwood Taylor, M.R.C.S.E., aged 53.

WILTON.—On the 11th April, at Bishopwearmouth, Sunderland, John Wilton, M.D., aged 80.

WINTER.—On the 9th April, at Westbury, William Thomas Winter, M.R.C.S.E., aged 37.

GENERAL NURSING INSTITUTE for TRAINED HOSPITAL NURSES.
5 Henrietta Street, Covent Garden, W.C.
A. EBSWORTH, F.R.C.S., Director.

MEDICAL DEFENCE ASSOCIATION.—This Association of Registered Medical Practitioners is fully organised and in active operation.—Further particulars as to the objects of the Association, together with copies of the rules, may be obtained of the Hon. Secretary, Mr. George Brown, M.R.C.S., 12 Celebrooke Row, London, N.

ST. BARTHOLOMEW'S HOSPITAL and COLLEGE.—The SUMMER SESSION will commence on MONDAY, May 1.

The Clinical Practice of the Hospital comprises a service of 710 beds, inclusive of 30 beds for convalescents at Highgate.

Students can reside within the Hospital walls, subject to the College Regulations.

For all particulars concerning either the Hospital or College, application may be made, personally or by letter, to the Resident Warden of the College, or at the Museum or Library. A handbook will be forwarded on application.

ST. GEORGE'S HOSPITAL MEDICAL SCHOOL.—The SUMMER SESSION commences on MONDAY, MAY 1st. The Hospital contains 350 beds. Clinical Lectures are delivered by the Physicians and Surgeons every week. In addition to the usual Courses of Lectures given by the appointed Teachers, Lectures are also given on Comparative Anatomy, and on Dental and Aural Surgery. The William Brown Exhibition of £100 per annum will be competed for at the end of this Session. Further information may be obtained from the Treasurer or Dean of the School, at the Hospital.

THE LONDON HOSPITAL and MEDICAL COLLEGE.—The SUMMER SESSION will commence on MONDAY, May 1st. The occupation of the new wing will raise the total of beds to 800. Entrance Science Scolarships, Scholarships in the subjects of Preliminary Education in Anatomy, Medicine, Surgery, &c., amounting in the aggregate to £330 annually, are offered for competition. Numerous resident and outdoor appointments are open to students. Further information can be obtained on application to the Beadle of the London Hospital Medical College, Turner Street, E. Greatly increased facilities are now afforded by adjacent railways and tramways for rapid transit from the neighbourhood of the Hospital to other parts of London and the suburbs. Lodgings can obe btained in healthy localities in the immediate vicinity of the Hospital at a very reasonable charge.

UNIVERSITY COLLEGE, LONDON.—FACULTY OF MEDICINE.—The SUMMER SESSION will begin on MONDAY, May 1st. Prospectuses containing full information respecting the Classes in the College, Clinical Instruction at the Hospital, Scholarships, Exhibitions, &c., may be obtained at the Office of the College, Gower Street, W.C.

H. C. BASTIAN, M.D., F.R.S., Dean of the Faculty.
HARRY BROWN, Assistant Secretary to the Council.

CHARING CROSS HOSPITAL and MEDICAL SCHOOL.
SUMMER SESSION, 1876.

LECTURES and CLINICAL INSTRUCTION in the Wards will commence on MONDAY, MAY 1st.

Gentlemen can enter to any Course of Lectures or to Hospital Practice only.

The Hospital, on the completion of the new buildings, will have a service of 236 beds for Clinical Teaching, including those of the adjoining Royal Westminster Ophthalmic Hospital, to which Matriculated Students are free.

TWO ENTRANCE SCHOLARSHIPS of £30 and £20 respectively are awarded annually in October, for which Candidates are required to give notice of their intention to compete on or before Saturday, September 16th.

The LLEWELLYN SCHOLARSHIP of £25, and the GOLDING SCHOLARSHIP of £15, open to Matriculated Students who have completed their second and first academical years respectively.

Students are eligible for the Appointments of Medical and Surgical Registrar (salary £40 each) and to the Offices of Resident Medical, Surgical, and Obstetrical Officer, and for Clinical Clerkships and Assistant Demonstratorships of Anatomy, without additional fee.

The Fees for the entire Course of Lectures and Hospital Practice required by the Examining Boards amount to £80 8s. The Composition Fee for Dental Surgery is £42 2s.

A Prospectus containing every information will be forwarded on application.

The Librarian attends daily at the Office of the School, Chandos Street, Charing Cross, between the hours of 10 and 4

FRANCIS HIRD, Dean.

GLASGOW.

ANDERSON'S UNIVERSITY.—MIDWIFERY CLASS.

Dr. J. G. WILSON, Consulting Physician to the Glasgow Maternity Hospital, &c., will commence his course of Lectures on Midwifery on Tuesday, the 2nd May, at 3 P.M.

Further particulars may be obtained at Anderson's University.

UNIVERSITY of LONDON.—PRELIMINARY SCIENTIFIC M.B. EXAMINATION.—Instruction is given at GUY'S HOSPITAL in all the subjects required for this Examination, by Lectures and Special Classes during the ensuing Summer Session.

For further information, apply to Mr. I. Stocker, Medical Secretary, or the Dean, Dr. F. Taylor.

Guy's Hospital, S.E.

HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, BROMPTON.

Two Courses of Clinical Demonstrations will be given in this Hospital during the months of May and June, 1876.

"On Variations in Cardiac Rhythm." By E. SYMES THOMPSON, M.D., F.R.C.P. On Mondays, at 3 o'clock, beginning May 8th.

"On Clinical Types of Heart Disease." By I. BURNEY YEO, M.D. This Course will consist of about Ten Demonstrations, and will be given every Wednesday, at 3 o'clock, beginning May 3rd.

Fee for Hospital Practice (including all Clinical Courses), for Three months, 3 Guineas; Six months, 5 Guineas; Perpetual, 10 Guineas. Fee for a single Course, 2 Guineas.

PHILIP ROSE, Hon. Sec.
HENRY DOBBIN, Sec.

CLINICAL ASSISTANTS and OPHTHALMIC DRESSERSHIPS, 1876-7.

NOTICE.—Gentlemen who have entered to the practice of the ROYAL LONDON OPHTHALMIC HOSPITAL, and who are desirous of undertaking the duties of Clinical Assistant for one year, from the 1st of May next, are requested to forward their names in writing to the Honorary Secretary of the Medical Council, or to the Secretary of this Hospital, previous to the 22nd of April next. The Appointment is held for one year, but the officer is re-eligible on the recommendation of the Medical Council. Those gentlemen who, on the expiration of their term of office on the 30th of April next desire to be reappointed, will be good enough likewise to signify their intention as above. Anyone applying must undertake, if appointed, to perform the duties for one year certain.

Ophthalmic Dresserships have also been instituted for the performance strictly of the minor duties of the out-patient department. Anyone applying for these Appointments must undertake, if appointed, to hold them for six months.—Apply as above.

April 1st, 1876. ROBERT J. NEWSTEAD, Secretary.

LONDON HOMŒOPATHIC HOSPITAL and MEDICAL SCHOOL.

The following lectures are arranged for the coming months

These lectures were instituted by the British Homœopathic Society and are to be delivered on each succeeding Thursday, at the Hospital in Great Ormond Street, Russell Square, W.C., at 5 P.M.

Dr. Drury on the Exanthematous Diseases of Children and on Whooping Cough, commencing on Thursday, April 27th.

Dr. Drysdale two lectures on the Theory of the Homœopathic Principle, on May 25th and June 1st.

Dr. James Jones two lectures on Ulcers of the Lower Extremities, and on the Homœopathic Treatment of some other Surgical Cases, commencing on Thursday, June 8th.

The Medical Officers of the Hospital have arranged to give Clinical instruction, tickets for admission for which will be granted on application to the Honorary Secretary.

Medical men are invited to attend these courses of lectures. Medical students will receive cards of admission on application to

WILLIAM BAYES, M.D.,
Honorary Secretary to the Lectures' Committee.
4 Granville Place, PortmanSquare, W.

BRISTOL MEDICAL SCHOOL

The SUMMER SESSION will commence on MONDAY, May 1.

Prospectuses may be obtained on application to
GEORGE F. BURDER, M.D., Hon. Sec.
Medical School, Old Park, Bristol,
April, 1876.

OWENS COLLEGE (MANCHESTER ROYAL) SCHOOL of MEDICINE.
SUMMER SESSION.

Midwifery and Diseases of Women and Children—Dr. Thorburn.
Materia Medica and Therapeutics { Mr. Somers. / Dr. Leech.
Morbid Histology—Dr. Dreschfield.
Ophthalmology—Mr. Windsor.
Practical Chemistry—Prof. H. E. Roscoe, F.R.S.
Botany—Prof. W. C. Williamson, F.R.S.
Forensic Medicine and Hygiene—Dr. Arthur Ransome.

The Session will commence on the 1st MAY.

Prospectuses will be forwarded on application.

J. HOLME NICHOLSON, Registrar.

ROYAL COLLEGE of SURGEONS in IRELAND.

NOTICE is hereby given that on TUESDAY, the 2nd day of MAY next, at the hour of 2 o'clock, p.m., the President, Vice President, and Council will proceed, according to the provisions of the Supplemental Charter, to elect from among the Fellows of the College, Eight Examiners, to Examine Candidates for Fellowship and Letters Testimonial. Three Examiners to Examine Candidates for the Diploma in Midwifery; and Three Examiners to Examine Students as to their proficiency in General Education.

Candidates are requested to lodge their applications with the Registrar, at the College, on or before Friday, the 28th of April.

By Order,
JOHN BRENNEN,
April 22nd,, 1876. Registrar.

THE PATHOLOGY AND RELATIONS OF ALBUMINURIA. (*a*)

By W. Howship Dickinson, M.D., F.R.C.P.,

Physician to, and Lecturer on Pathology at, St. George's Hospital; Senior Physician to the Hospital for Sick Children.

LECTURE I.

I propose to bring under consideration some of the larger facts which are connected with the several forms of renal disease characterised by an albuminous state of the urine, marking their pathological distinctions, tracing their points of mutual relationship, and touching upon their associations with organic changes external to the kidney, or more or less widely distributed through the economy.

The organic conditions of persistent albuminuria may be broadly divided into three :—

First, *nephritis, tubal or diffuse*, the product of simple inflammation of the secreting structures. This, though essentially tubal, may, if intense or long-continued, involve the interstitial tissue in the inflammatory process, and supply the granular kidney with one mode of origin.

Secondly, the *granular kidney*, or the *kidney of chronic interstitial hypertrophy*, usually beginning as an independent change, but possibly a sequel of the more acute disorder.

Thirdly, the *lardaceous kidney*, a condition in which this gland participates only in an infiltration common to many organs and tissues of a material different from any of the normal constituents of the body.

The first begins with changes local to the kidney, but often ends in results general to the arterial system ; the second is so constantly associated with arterial changes that it is disputed whether the renal and the arterial are cause and effect or are simultaneous results of circumstances antecedent to both ; the third begins, without question, systemically, producing renal disease as only one of a series of secondary organic changes. Each of these conditions has its points of contact with the others. Nephritis at first tubal may end intertubally, and thus, however rarely, the large smooth kidney become small and granular. The granular kidney, or the kidney of interstitial fibrosis, though usually of independent origin, may take its rise in either of the other forms of change. And the lardaceous state, to complete the complicated relationship, may set up renal inflammation, whether of the tubes or of the interstitial tissue.

I will touch in brief and general terms upon the origin, nature, and connections of each disorder.

Tubal or diffuse nephritis—for tubal nephritis so often begins diffusely, or becomes diffuse, that no more definite separation can be made between them than between slight and severe—is a catarrhal exasperation of the secreting function, due to some excessive or unsuited stimulus. Mere tubal catarrh, with attendant obstruction and congestion, is happily in a large majority of cases, the only organic change ; but when the process is intense or persistent, it is apt to cause in the interstitial tissue a delicate hypernucleation which, in its early stages, may easily escape notice, but may lead in the end to fibroid thickening. The smooth, swollen kidney, white or red, as blood or epithelium predominate, may acquire in the end a granular inequality of surface, should the interstitial tissue become involved and time be given for consequent changes. It may be laid down as an axiom in renal pathology that granulation invariably implies fibrosis. No mere tubal condition, whether of distention or collapse, breaks the superficial level.

Thus, according to date and intensity, the following outline may be drawn of the phases of renal inflammation :—

1. *The congested kidney.*—The blood-dripping kidney or acute congestive nephritis.

2. *The large white kidney.*—Swollen and pale, either absolutely smooth or but sparsely dimpled ; dependent upon nephritis mainly, and from the first tubal, but which may have come to involve the intertubal tissue. Superficial

(*a*) Abstract of the Croonian Lectures.

depressions, if they exist, are a sign that it has become thus complicated.

3. *The contracting kidney of nephritis.*—Granulating and fibrotic like the granular kidney of latent origin ; not often thus ensuing upon acute inflammation, but to be recognised as a rare and late result.

The intimate mechanism of these changes may be briefly reverted to. The first noticeable changes are an excessive production of epithelium and an excessive influx of blood; the epithelium cemented into cohesion by the fibrine which escapes from the overloaded vessels. The congestive type is well marked, and often rapidly fatal. It may be attended with swelling so great and so sudden that the capsule of the kidney may actually burst and bleeding take place into the areolar tissue of the loins. In this intensely congestive form scattered spots of nucleation may be found, perhaps not uniformly, but sometimes abundantly, in the interstitial tissues both of cones and cortex. And in the slower form, which is marked by the large white kidney, similar germs of interstitial fibrosis may be detected in severe or protracted cases. Morbid change to be simple must generally be recent ; not that all recent disease is necessarily simple. When nephritis is protracted, and even sometimes when of recent origin, the nuclei of the interstitial tissue swell and multiply; they become numerous and conspicuous in each of the once pellucid bars by which the secreting elements are separated, and may even occupy so much of the section as to exclude nearly everything else from view. This helps to give its extravagant bulk to the white kidney of old date, and to render return to health impossible. I have not dwelt upon the tubal changes which are essential to the disease, and are the main cause of its symptoms. The epithelial accumulation and its frequent fatty change under the inflammatory process are well known. The catarrhal change is first to come and may be first to go. The nucleation may outlast the catarrh and remain when the tubes have for the most part recovered themselves, as the only prominent change. Usually the two persist together, and with tubal distinction and intertubal nucleation, much increase of bulk, and a still smooth surface, the large white kidney finds its close.

More rarely, time is given for the nuclei to develope into fibre, the fibre to contract, and the surface to granulate. In answer to the question, how long it takes the once smooth kidney of nephritis to become granular ? I may refer to the case of a boy who died at the age of eleven with this state of kidney, as the result, apparently, of scarlatina three years before ; with a girl who died of the same disorder at the age of twenty-one, it was traced with equal probability to scarlatina eleven years before ; and probably in most cases in which the course of nephritis can be counted by years more or less interstitial fibrosis, and its result in superficial granulation, can be detected.

Passing from the kidney itself to the changes consequent upon its disturbance in other organs and tissues, affections of the inflammatory sort, chiefly such as concern the respiratory organs, are the most frequent and the most fatal in childhood ; while the dropsical and uræmic results of the disease are the most mischievous in later life. In the next place, it is of interest to inquire whether any secondary arterial or cardiac affection can be recognised in connection with this inflammatory form of renal disease, since the answer may throw light upon the disputed origin of the cardio-vascular changes which are so common with the granular kidney.

I have examined somewhat carefully into the state of the arteries and of the kidneys in as many well-marked cases of inflammatory disease as recent opportunities have allowed. The results are displayed in a table [which gave the particulars of five cases of acute renal dropsy, all in young and previously healthy subjects ; four were children varying in age from six to thirteen, the fifth a girl of nineteen ; the duration of the disorder varied from ten weeks to as many months]. In all, the arterioles were thickened and the heart hypertrophied. In each case the arterioles were carefully compared with those of health and of the same time of life, prepared in precisely the same manner, many different methods being used. As to the result, there was no doubt the thickening involved both muscular and fibroid coats, though neither to the extent found with the granular kidney. [Diagrams, made with the camera lucida, showing the exact relative thicknesses of the morbid as compared with healthy arteries, were exhibited]. Degenerative changes, especially in the nuclei, were noticed in some of the cases. A conclusion of great importance is forced upon us by the facts : that under the influence of renal disease of inflammatory origin in previously healthy subjects the arteries undergo changes similar in kind to those which accompany the granular kidney, however small in degree. But while these changes certainly ensue upon disease at first local to the kidneys, it is not so easy to assert that they occur independently of renal fibrosis, since some degree of incipient fibrosis or nucleation is generally to be found in the kidney where the disease has lasted long enough to set up the cardio-vascular change. But considering the youth and previous health of subjects, and the inflammatory nature of the attack in each instance, it is quite clear that both the fibrosis and the arterial thickening were results of the local glandular disturbance, not parts of a general deterioration.

With these arterial and cardiac changes are to be noted an increase of arterial tension as appreciated with the sphygmograph, and occasionally its retinal results in hæmorrhages and white spots.

Thus, to conclude a crucial part of a debated question—vascular tension, cardiac hypertrophy, arterial thickening, and retinal hæmorrhage, all are to be found with, and are presumably caused by, disease beginning locally to the kidney as the result of inflammation.

To pass now to the more chronic disease, which is recognised by the granular kidney, and caused by creeping fibrosis, we have to describe a condition which begins with and belongs essentially to the connective and vascular structures. The change begins in a disproportioned growth, somewhat of a rank luxuriance, in the fibroid tissue with which the arterial channels are uniformly fringed. Hypertrophy of this part leads to atrophy of the rest, creeping along the arterial lines with slow and hesitating steps, involving the organ not all at once, but by little and little; the disease makes itself felt so gradually that its date is usually indeterminable, and in other respects, too, it affords a precise contrast to the more acute disorder.

The organic derangement is declared pathologically by the superficial loss of level, to which the term granulation is applied. This condition is only produced by a drawing-in of the surface at certain points by a contractile growth, the distribution of which is determined by that of the blood-vessels around which it begins. The essence of the disease as it first takes substance and shape is a multiplication of nuclei, with subsequent fibrillation in the interstitial tissue. Spreading inwards along the arteries, surrounding concentrically the Malpighian bodies, imbedding, compressing, and strangulating the tubes in its path, while others for a time escape only to yield to its later encroachment, the growth overruns the gland after the manner of the invader who likened his scheme to the eating of an artichoke leaf by leaf. The new growth is different in its rich nucleation from the original fibrous tissue of the organ. It occurs sometimes in great masses and developes capillary bloodvessels within itself. [These particulars were demonstrated from diagrams.]

To touch upon the changes which ensue in the gland upon its occupation by this growing and contracting material, they are due in part to its bulky presence, and in part to its constricting action ; the former are best seen in the rare granular kidney of childhood, the latter in the more chronic form which belongs to advancing life. The tubes are variously distorted parcelled by the fibroid tissue into insular groups, cut up into cysts and compressed to impenetrable threads. The epithelium suffers little ; late in the disease it is variously distorted by pressure.

Besides the slow and gradual accession which is the rule

of the disease, it is to be distinctly recognised that the disorder may be an immediate though slowly declared sequence of acute nephritis. The general interstitial nucleation which may be left by the inflammatory process may grow into fibre, and the fibre contract until at last the granular kidney results. This origin, however, of the granular kidney is exceedingly rare.

Passing to the cardio-vascular changes which accompany the granular kidney, hypertrophy of the heart, though not invariably present with it, is so frequently so as to be a most valuable clinical diagnostic of the renal condition. With regard to the arteries, these broad modifications are to be recognised as contributing in different proportions to their change—first, a thickening with alteration of texture of the muscular coat; secondly, a thickening of the fibrous coat; thirdly, a degeneration which chiefly affects the muscular coat, but may in the end supersede every other morbid process, and replace all distinction of coat by a mere confusion of granules and fat. [These changes were illustrated by diagrams, and explained in further detail.] The thickening of the outer coat is not to be attributed to the action of the reagents, since it can be displayed with any. The hypertrophy of the fibrous coat is a real pathological change, and that of the muscular not less so. It seems that the muscular hypertrophy often appears earlier than the fibroid. The ultimate degenerative changes, which chiefly belong to the muscular, are the chief agents in causing the brittleness of vessel to which the hæmorrhagic proclivities of the disease are so largely due.

As with the kidney of nephritis, but more markedly with the disease now under consideration, these changes in the circulating system are attended with an increase of arterial tension, a concurrence which has recently been fully treated of in this room by Dr. Sibson.

ON SPINAL INJURY. (a)

By Frank Thorpe Porter, L.K.Q.C.P.I., &c.,
Demonstrator in Anatomy, Ledwich School of Medicine.

The subject of Spinal Injury is at all times pregnant with interest, whether it be viewed in its surgical bearing on the one hand, or its relation to questions concerning the physiology of the nervous system on the other.

The publication of the notes of this case, which I have the honour to detail to the Society, was first suggested to me by the perusal of Dr. Barton's highly instructive paper on "Spinal Injury," inasmuch as his case and mine present some interesting points of contrast.

The patient, a married woman, æt. 50 years, came under my notice on the 22nd of November last, and gave me the following history of her case: That on the evening of the 20th of November she was leading a child up a short flight of stairs, on reaching the top of which she fell backwards, the small of her back coming with great violence against the first step below. She had sustained a fall of 15 feet. She was very much stunned, and for some time was unconscious. On coming to herself she found that she was unable to get up without assistance, and on attempting to walk was unable to *move* the *legs*, in which at the same time she *had lost all sensation*. She was attacked with a looseness in the bowels, which came on suddenly, but which ceased as the effects of the shock passed away.

I made a most minute digital examination of the spinal column, but was unable to detect any displacement; pressure on the lumbar portion of the spinal column caused, however, a most excruciating degree of pain; pressure in the right hypochondriac region produced severe pain also. There was a large ecchymosed patch extending over the back of the sacrum and sacro-iliac joints. The patient was unable to turn in the bed or to sit up; efforts to turn her caused considerable pain. There was no vomiting at any time, but hiccough was present to a remarkable degree. The urine was retained, and had to be drawn off daily; but the patient *could force* the stream *through* the *catheter*, clearly showing that there was considerable control over the abdominal muscles. When first called in, the urine was strongly acid, and highly charged with lithates, there being at first no trace of any other abnormal constituent. There was at no time any relaxation of the sphincter ani, and with the exception of loss of appetite, there was nothing abnormal in connection with the digestive system.

There was nothing striking about the pulse, except its being intermittent. The temperature was normal, except in the leg, which was very cold.

The treatment consisted of the exhibition of mercury in small doses (hyd. c. creta, gr. ii. omne hora tertia). The mercurial treatment was continued for four days, at which time the gums looked tender. Iodide of potassium or bark mixture was then administered, and at the same time tr. iodine was applied along the spine.

At the end of the 10th day, when the acute symptoms had more or less subsided, I prescribed small doses of the liq. strychniæ; the exhibition of the strychnine was followed by a *complete return* of the sensation in both legs and by a temporary return of strength generally. I, however, did not persevere in the remedy for a longer period than a few days.

At the end of the second week the urine underwent a change—it became alkaline and albuminous; this condition was only manifested on e, although I tested the urine every day. This state of the urine set in after it had been retained for some hours. This temporary alkaline and albuminous condition was followed by the appearance in abundance of the acid phosphates—the result no doubt of the metamorphosis of nervous tissue. Writers on spinal diseases consider the acid state of the urine to be favourable towards recovery; but I must dissent from such opinion when acid phosphates are eliminated.

Towards the commencement of the third week the patient lost ground, became weak, and was placed on bark and a plentiful allowance of stimulants, including champagne. A large bed-sore formed over the sacrum, owing in a great measure to the neglect on the part of the patient's friends in not providing an air-cushion or water-bed. The bed-sore was accompanied by furred tongue, low delirium, insomnia, and general symptoms of septicæmia, and death ensued three weeks and five days after receipt of injury.

I was not allowed a post-mortem. I made, however, an inspection of the body. The body generally was very much attenuated, the abdominal walls being so thin that I could pass my hands with facility along the front of the vertebral column, which felt almost subcutaneous, but not in the least displaced.

I then made a minute examination of the bed-sore, and could in one spot, between 3rd and 4th piece of the sacrum, which was greatly exfoliated from the effects of the bed-sore, pass my finger into the spinal canal. I imagine I felt the corda equina, which felt softened. I had previously examined this part after the occurrence of the accident, but could detect no fracture, so that I am induced to attribute the opening into the spinal canal solely to the destructive energy of the bed-sore.

I looked on the case to be one of sprain or rupture of the motor columns of the cord with temporary pressure (from effusion perhaps) on the sensitive columns, ultimately giving rise to softening of the cord. I did not consider the case as one of fracture or dislocation for many reasons, especially the absence of that degree of displacement which would accompany fracture or dislocation capable of causing such a degree of paralysis.

I speak of the sensitive and motor columns, but I am not prepared to say which columns are motor and which are sensitive. Sir Benjamin Brodie considered that the anterior columns were motor in their functions; but

(a) Read before the Surgical Society of Ireland on April 7, 1876.

other physiologists of note, including my friend Dr. Mapother, hold an opposite opinion. I am not prepared to say which is right, but the question furnishes a wide field for discussion at the hands of a society like the Surgical Society of Ireland, which can lay claim to be one of the most suitable arenas for an interchange of views between the toiling practitioner and those more philosophical brethren to whom opportunity and taste have alike afforded facilities for the investigation of the more purely scientific problems. The points of interest in the case are to my mind—1, the complete absence of any relaxation of the sphincter ani, notwithstanding Mr. Erichsen's opinion to the contrary that relaxation of the sphincter is always a sequence of injury to lumbar or lower dorsal regions of the cord; 2, the complete return of sensation in the legs; 3, the ability of the patient to force the stream of urine through the catheter; 4, the sudden appearance for a few hours of albumen in the urine, followed by its equally sudden disappearance; 5, the persistent acid state of the urine, although writers on spinal injuries and diseases consider the alkaline condition to predominate in all, or nearly all, cases.

In conclusion, I would wish to elicit discussion on the following points: The diagnosis between fracture and other injuries of the spine; the value of the state of the urine as an index of the relative gravity of nervous lesion; and lastly, the value of mercury and strychnia, as also the time most suitable for the proper administration of the latter remedy.

I am indebted for the opportunity afforded me of observing this case to my friend Dr. McEntee, the resident physician at Grand Canal Street Dispensary, who called me into consultation, and who handed the case over to me.

A CASE OF COMPLICATED LABOUR, IN WHICH COLLAPSE FROM POST-PARTUM HÆMORRHAGE WAS TREATED SUCCESSFULLY BY THE SUBCUTANEOUS INJECTION OF ETHER. (a)

By A. V. Macan, M.B.,
Assistant-Physician to the Rotunda Hospital, and Obstetric Surgeon to the City of Dublin Hospital.

The patient, who was pregnant for the 11th time, had had good health till within nine weeks of her confinement. She then began to complain of a gnawing pain in the lumbar and hypogastric regions. The abdomen was much larger than in any of her former pregnancies, which was caused by hydrops amnii. The amount of urine passed was much below the normal quantity. The labour was very tedious, from uterine inertia. The membranes were therefore ruptured, when an immense quantity of liq. amnii escaped. The fœtus belonged to the class of anencephalous monsters, the diagnosis resting chiefly on the unusual shape of the mastoid processes, and the violent movement of the fœtus when the finger came in contact with the exposed portion of the medulla oblongata. It was born without artificial assistance, but its birth was followed by post-partum hæmorrhage and retention of the placenta. This necessitated the manual removal of the placenta, which was accompanied with but slight additional loss of blood. The woman, however, got gradually worse, exhibiting all the symptoms consequent on severe loss of blood. I therefore determined to try the effect of the subcutaneous injection of ether, as recommended by Professor v. Hecker, of Munich (vide *Irish Hospital Gazette* for June, 1875). As some blood was still escaping *per vaginam*, I thought it necessary to combine it with the injection of the perchloride of iron into the uterus. Soon after 45 min. of ether had been injected well into the cellular tissue of the abdominal walls reaction suddenly set in. The change was so sudden and unusual that no doubt could be entertained that it was due to the ether. The woman's convalescence was rapid and uninterrupted, she being able to leave her bed on the twelfth day.

The chief point to be attended to in making the injection is to pass the syringe well down into the subcutaneous cellular tissue, otherwise troublesome abscesses may form at the seat of the injection. The quantity to be injected depends entirely on the pulse. Professor v. Hecker frequently injects from ʒij. to ʒiv. at short intervals. The effect is very transient, so that the injection may have to be repeated. Its use need not be confined to collapse from post-partum hæmorrhage. I have also tried it in accidental hæmorrhage, rupture of the uterus, and puerperal fever, in all cases with more or less effect. Dr. Atthill, the present Master of the hospital, has used it with good effect in a case of placenta prævia, and it has been used by Dr. Bennett and Dr. Croly for collapse in cases of strangulated hernia. Professor Winckel, of Dresden, has used it in a case of pulmonary embolism following delivery, where it completely relieved the intense paroxysms of dyspnœa.

I think that further experience alone will enable us to settle the exact value of this mode of treatment, which is at all events worthy of serious consideration.

(a) Read before the Dublin Obstetrical Society, March 11th, 1876.

STRANGULATED HERNIA—OPERATION—CURE.

By J. J. M'Keogh,
Medical Attendant to Workhouse, Kilmacthomas, Co. Waterford.

J. R., æt. 28, labourer, was seized on the 7th March last, at seven a.m., with a large oblique strangulated scrotal hernia on right side. His own statement is: "On the morning in question, on rising from bed, he forgot to put on his truss, and having gone a very short distance from the house, he felt a pain in the lower part of abdomen; he then returned for truss as quickly as he could, and found on reaching the house that his bowels had come down, forming a very large hard tumour; his sufferings were so intense that he begged of his employer to shoot him to put him out of pain." He says he was first seized with this two years previously, and on some three or four occasions reduced it himself, but that the descent was only partial. I saw him on the followlng morning in the infirmary, and having put him under the influence of chloroform, I endeavoured by taxis to reduce it, but failed. I then punctured tumour in six different parts with a grooved needle, thinking if bowel contained flatus I would thus let it off, and so by diminishing the volume of hernia I could reduce it. In this I also failed. He then had a purgative enema and cold applied locally. This, too, was ineffectual. Dr. Walker, of Bunmahon, saw him in consultation with me on the third day, and directed gr. i. of opium to be given every second hour, hoping that when he got under the influence of the opium it might undergo a spontaneous reduction, or if not, could be reduced by taxis. This likewise was inoperative. On the fifth day again I had the benefit of Dr. Walker's opinion. Patient was sinking; vomiting had continued from the first, but on this day was much worse, for on two occasions he vomited large quantities of black fluid. We now thought it advisable to have the Drs. Martins' advice, of Portlaw. They were sent for, and came same evening. Having examined patient, it was agreed to, as a *dernier ressort*, to operate at once.

Patient left his bed and placed himself on the table. He then had chloroform and ether administered to him. When complete anæsthesia was produced, I then proceeded to operate after the usual manner, but when I had been about half way in the operation, he fell into a state of profound collapse, which became very alarming for six to eight minutes, during which I had to suspend the operation. When he was sufficiently brought to I resumed, and having come down on the sack, it was my intention to divide the stricture externally to it; but having made a careful examination, I could not find it (the stricture), so I was

then obliged to open the sac. Now after exploring the parts with the finger, I at last found the stricture, deeply situate, strong and tense. I divided it in the usual way, and returned bowel and omentum (contents of sac first, omentum, and next bowel). After this the sickness and vomiting immediately ceased. The wound was now closed in the ordinary manner. There was very little hæmorrhage, only two small arterial branches requiring torsion. The opium by the mouth was now discontinued, and instead one-third grain of morphia was injected three times daily into skin of abdomen. I chose the latter on the suggestion of M. Vibert. He was directed to have ice in the mouth *ad lib.*, and a large warm turpentine stupe over abdomen, and to be repeated. There was no peritonitis at any time. On the following day vomiting and hiccough returned, and proved rebellious to all treatment, so that his strength had to be maintained by enemata of beef tea, frequently repeated in the twenty-four hours. On the night of the 16th there was a spontaneous action of the bowels. After this the vomiting and hiccough ceased, and he could bear food on his stomach. Hypodermic injections were now discontinued. From this forward he progressed rapidly. The wound was dressed throughout in as strict accordance as I could with Professor Lister's antiseptic plan; for in this infirmary I must say surgical appliances of every sort are of the poorest description. I consider Professor Lister's plan invaluable in the treatment of wounds.

I desire to convey my best thanks to the Drs. Martin and Walker for the very efficient aid they afforded me during the operation.

OBSTETRIC OPERATIONS.

By T. M. Dolan, L.R.C.P.Ed., L.R.C.S.,
Medical Officer Halifax Union Infirmary, Physician to the Halifax Fever Hospital, Yorkshire.

The variations in number of operations, deaths, &c., occurring in different midwifery practices, as recorded from time to time in our medical journals, are very singular, and offer food for consideration as to the causes of the wide discrepancy between one practitioner's experience and another's. Some accoucheurs rarely or ever use the forceps, others have never had a death, and would almost induce us to think the process of child-bearing was unattended by danger to life.

An inquiry into the cause of this variation must be interesting to all obstetricians. But can it be solved? Must we assume greater skill, manipulative power, patience, &c., on the part of some accoucheurs? Or does the chaste Lucina bless some favoured practitioners of her art? The difference in number of operations, deaths observed in the records of modern correspondents, singularly coincide with the variations observed in the practice of some of our eminent obstetricians, past and present. The following tables, taken from Churchill's excellent monograph, illustrate very forcibly the truth of my remarks:—

Table A.—Forceps Cases.

	Total.	Forceps.
Dr. J. Clark	10,387	14
„ Collins	16,414	24
„ Ramsbottom ...	68,435	112
„ Sinclair & „ Johnston ...	13,748	200
„ Hall Davis ...	13,783	15
„ Madame Boivin ...	20,517	96
„ Pigeotte de Troyes	1,362	2
„ Harper	6,053	302

Here are statistics sufficiently striking.

Compare Hall Davis, Sinclair and Johnston, and Harper's total number of cases and their relative use of instruments with the others on the list, and the question will suggest itself whether the former practitioners had a worse class of patients; or can the custom of using the forceps explain the difference?

Table B.—Craniotomy Cases.

	Total.	Craniotomy Performed.
Dr. Clark	10,387	49
„ Collins	16,414	79
„ Ramsbottom ...	68,485	85
„ Sinclair & „ Johnston ...	13,748	130
„ Hall Davis ...	13,783	15
„ Madame Boivin ...	20,517	16
„ Moshner & Kursa	12,329	4
„ Riecke	219,303	53

We must still observe the striking diversity in percentage of number of cases amongst almost the same practitioners. Assuming that these statistics are correct, we must presume that equal skill was possessed by all these eminent accoucheurs, and that a reasonable time was allowed for Nature to assist in the efforts of parturition, and that in every case craniotomy was absolutely essential. Have race and climatic influences an important part to play in the solution of this problem, or must we put down the diversity to the chapter of accidents?

My own experience in practice since 1866 enables me to furnish the following statistics, and may prove interesting to anyone engaged in the comparison of the percentage of operations and mortality in England:—

Number of Recorded Cases.

Halifax Poorhouse	63
Private Practice	1,370
Forceps	40
Craniotomy	5
Placenta Prævia	5
Twins	13
Deaths	9

I have found that my deaths occurred in the simplest cases, and that invariably patients considered bad made a good recovery.

The subject of puerperal fever must be interesting to all accoucheurs, as its occurrence in practice is such a serious matter to the young practitioner, and as there is such diversity of opinion as to the proper method of procedure. It opens, of course, the grave question whether midwifery practice should be abandoned, and for how long.

Unfortunately, in 1868, I had a typical instance of the disease, and of the difficulty to be experienced by a young practitioner when such an unfortunate circumstance happens to him.

My patient, a primipara, succumbed on the 10th day from that disease.

Two old practitioners, Drs. John Garlick and Peacock, were attending with me, and of the nature of the case I believe there can be no doubt.

The former insisted very strongly on the necessity of my giving up midwifery practice. I refrained for some time from attending such cases, but one night three cases occurred in my practice. A brother practitioner kindly went to one, but for the other two I could not obtain a substitute, so that, *nolens volens*, I was compelled to go. In both my cases the children were born, and I had to remove the placenta.

I watched necessarily with considerable anxiety their convalescence, and am happy to state both recovered without a bad symptom.

Of course I took all precautions as to clothes, hands, &c.

I then resumed practice, without any bad results to any of my patients. The result, as bearing on the question of the communicability of the infection, is negative, but does, I consider, perhaps strengthen the assertions of Dr. M. Duncan, as expressed in his sensible letter to the Secretary of the Obstetrical Society of London.

The annual dinner in aid of the the funds of the French Hospital in London will be given at Willis's Rooms next Saturday evening, at which his Excellency the Marquis d'Harcourt, the French Ambassador, will preside.

Transactions of Societies.

DUBLIN OBSTETRICAL SOCIETY.

THE fifth meeting of the session was held on Saturday, March 11th, the President, Dr. LOMBE ATTHILL, in the chair.

Dr. CHURCHILL, jun., read for his father a communication on six cases of retained ovum, in which ergot of rye had been administered with success, and the patients had all recovered. The author agreed with Dr. McClintock's views as to the difficulty of diagnosis in these cases. In all the cases described in Dr. Churchill's communication there was an absence of the ordinary symptoms of pregnancy, but the circumstances were highly misleading. If the uterus contained nothing, but was enlarged from other causes, the ergot and sound could do no harm, and would not interfere with any other treatment that might be found necessary. When the fœtus was dead some months before expulsion, he had not known any fœtor to emanate from the discharges.

The PRESIDENT said the subject that had been brought before the Society by their absent ex-President, Dr. Churchill, was an extremely interesting and important one for discussion. He (the President) had had a very interesting case of the kind under his observation, in which the ovum was retained for eleven months, and in that case the prominent symptom was the total suppression of menstruation. After being pregnant some eight or ten weeks she met with a slight accident, and had an attack of hæmorrhage, followed by severe pain. Subsequently the discharge ceased, and for the succeeding nine months there was no return whatever of the menstrual discharge, or any sanguineous discharge whatsoever, but her general health continued good. She was kept in hospital, and the examination which was made seemed sufficient to excite uterine action, and in the course of twenty-four hours she expelled a mole. He had also a case in which a lady, after five months' pregnancy, retained a dead fœtus for more than three months. Dr. Churchill appeared unable to decide the exact duration of pregnancy in the cases he had described, but it might continue for a considerable time. In every case the retention ended in the death of the fœtus, and the fœtus and the rest of the products of conception were retained in utero for a very little time, giving rise to various symptoms, each case differing from the other.

Dr. MCCLINTOCK said the cases were very perplexing in practice, and caused a great deal of anxiety to the patient and her friends, and the negative course that the medical man was often obliged to pursue was rather trying and difficult. The whole question would narrow itself into this (where there was a suspicion of the woman being pregnant), and the solution of which would clear up all difficulties with regard to treatment—Was the woman carrying a living embyro or not? If she was pregnant, but the embyro lifeless, they might pursue any treatment: but that was a most difficult question to decide, and in the absence of positive information from the patient herself as to her being pregnant, of course a very cautious line of treatment must be pursued. Dr. Churchill seemed to have been very fortunate in the treatment of his cases, that he was enabled to accomplish the expulsion of the ovum by the use of the sound, and the administration of ergot of rye, for cases were occasionally met with where such mild measures as these were quite insufficient to effect the emptying of the uterus, and, of course, until that be done, and any remains of the ovum removed, the woman was liable to hæmorrhage. He believed, however, that cases would be occasionally met with where those measures would completely fail. The use of plugging very often had a beneficial effect in bringing about expulsive action in the uterus. A man would, however, hesitate before employing the plug as long as there was any possibility of preserving the ovum if there was not ground to think it was living, for it was almost certainly followed by expulsive action of the uterus.

Dr. KIDD said a case of the kind had lately come under his observation which illustrated the difficulty which Dr. McClintock had spoken of as to the position in which the medical man was placed, for he believed he was very frequently likely to be considered as not knowing what he was about—in fact, in some instances, not to understand the case at all. Some time ago a lady came to Dublin who had been in India, occupying a very prominent position there, and soon after coming to Dublin she had some hæmorrhage from the uterus. He was sent for, and gave it as his opinion that she was threatened with a miscarriage. However, she would not believe she was pregnant at all, and after undergoing a very careful examination, he reiterated his opinion that she was threatened with miscarriage, and that she was pregnant. She had, however, passed the period when quickening would have occurred. She had had several children; more than five months had passed since her previous menstruation, and the uterus, she said, had ceased to grow, for she maintained it was a tumour. He could not hear any sound in the tumour, and the breasts did not exhibit the plain indications of pregnancy. When he examined the uterus he was quite able to ascertain that the tumour was a uterine one. Then the os uteri had the peculiar soft pulpy feel that the os uteri had in cases of pregnancy, but as far as his experience went, it never had in cases of uterine tumour. That lady had repeated attacks of hæmorrhage, and he watched the case for some time. One day, however, the lady's discontent arrived at such a pitch that she sent for Dr. McClintock, but he refused to see her when he learned that he (Dr. Kidd) had charge of the case. She then went to London, and consulted one of the most eminent obstetricians there, but he (Dr. Kidd) believed the gentleman was led away by the statements of the lady, for he sent her to Croydsbach to get rid of the tumour, which, however, proved to be a four months' fœtus. There was no doubt that all these cases were involved in great difficulty, and that their diagnosis was exceedingly obscure. He believed that the diagnosis of these cases must depend in the first place upon the history. They had the history of the symptoms of early pregnancy, then these symptoms ceased, the breasts diminished, the tumour ceased to grow, and the symptoms of pregnancy gradually disappear, and then they had hæmorrhage, or serosanguineous discharges taking place. When they had cysts they found the tumour did not correspond with the period of pregnancy, as calculated by the patient, and yet they found that the os uteri presented that peculiar pulpy appearance which was, he thought, very characteristic of pregnancy, and at best, he believed, they must express a very qualified opinion with regard to it. The right thing for them to do in the first instance, at all events, was, he believed, to treat the patient as if she were pregnant, until there was indisputable evidence that the child was dead. They should not adopt any measures for ensuring its expulsion.

Dr. DENHAM said he thought that their attention ought to to be directed to the importance of preserving the life of the mother. He thought in cases of retained ovum in which there had been repeated hæmorrhages it was scarcely worth their trouble to preserve the ovum. In two of the six cases mentioned ergot seemed to have had a magic effect, and to have brought about immediate relief. His experience of the use of ergot was by no means commensurate with those facts. He had used it again and again without really much effect. If they came to the conclusion that active measures must be taken, he had no hesition in saying that they should apply the sound, which he thought was better than the exhibition of ergot.

The PRESIDENT would like to confirm what had been said by Dr. Denham with regard to the inefficiency of ergot in such cases as those of retained ovum. He believed in its effect in arresting hæmorrhage, but it did not necessarily expel the ovum, and he believed it had no effect in doing so.

Dr. MACAN then read his paper on

A CASE OF COMPLICATED LABOUR,

which will be found on page 358.

In the discussion,

The PRESIDENT said that the diagnosis in the cases of monsters gave rise to the greatest perplexity in the minds of the medical attendant. It was highly creditable to Dr. Macan that he should have so clearly diagnosed the case in the early stage. He had pointed out the very prominent symptoms of the hydrop. amnii, and the hydrocephalous monster. Recently he (the President) was asked to visit a case of placenta prævia. On his arrival he found the patient pulseless—in fact, she appeared to be moribund. The vagina had been well plugged, but the quantity of blood the patient had lost was very large. She had got out of bed very early in the night to pass water, when she got an attack of the hæmorrhage. The chamber was filled to two-thirds of its extent, and the bed was saturated. She had been given brandy freely—but unfortunately, she vomited freely in fact, it was vomited nearly as rapidly as it was taken. He decided on trying the effect of ether, and injected two

syringe-fulls—between forty and fifty minims. In a very short time he was able to leave the patient, and the next morning he delivered her of a dead fœtus. That patient had recovered without any bad symptom. In one case that Dr. Kidd saw some years since the patient's life was very nearly lost, and stimulants given by the mouth were useless. In ether they had a stimulant which he believed could be given safely and efficiently, and which the condition of the stomach rendered it impossible to be given in any but the one way. Within ten minutes after giving the subcutaneous injection they could smell the ether off the patient's breath. The paper of Dr. Macan was a most important one.

Mr. WILSON thought the Dublin school of surgery was deeply indebted to Dr. Macan for having brought the question so practically before them to-night. It seemed to him (Mr. Wilson) that they ought not to allow the question to lapse for want of discussion, because it was one of vital importance to the community. It was quite a novel method of treatment, and as all subcutaneous methods of treatment were, he thought, entitled to important consideration, he hoped that it would be very extensively published throughout Ireland that this plan of treatment had rescued a woman from death, and had been adopted by the Irish school of surgery.

Dr. MCCLINTOCK bore his testimony to the value and interest of the communication made by Dr. Macan, and hoped he would from time to time communicate to the Society any results that he might consider worthy of being brought under their notice. It was impossible to say anything about it except that it formed a most valuable acquisition to their *armamentarium*, and to possess many advantages over transfusion in being free from danger, and the operation easy of performance, whereas they all knew that transfusion occupied a good deal of time, and cost much trouble. He would wish to know from Dr. Macan, for information, whether ether had been employed in cases of poisoning by chloroform, for it appeared to him (Dr. McClintock) that this valuable restorative or stimulant might be very valuable under such circumstances?

Dr. MACAN, in reply, said that he could give no opinion on the subject. He was not aware whether it had been used in such cases.

The Society shortly afterwards adjourned.

MEDICAL MICROSCOPICAL SOCIETY.

AT the last monthly meeting of the Medical Microscopical Society, Dr. BATHURST WOODMAN read a paper

ON THE SYSTEMATIC STUDY OF HISTOLOGY.

One great object being to commend to medical students and practitioners a more systematic study of the microscope; in other words, not to confine their studies to the dead-house or the dissecting-room, or to the medical uses of the instrument, but to examine botanical specimens, anatomical and pathological specimens, and in fact, anything and everything that came in their way. Three or four fresh objects prepared each day would amount to nearly a thousand a year. The next point was an earnest recommendation to make a sketch or drawing (no matter how rough) of every object seen, either by the camera lucida or otherwise, and to preserve these drawings. Thirdly, to study micrometry. A cheap micrometer made by ruling lines on paper was shown by Dr. Woodman, whose fourth recommendation was, Work economically. Some cheap forms of apparatus were also recommended. The use of low powers as a means of training the eye, not to supersede, but to precede, high powers, and the regular or systematic use of a few reagents. Dr. Woodman concluded by strongly urging the formation of a library in connection with the Medical Microscopical Society, for reference, and perhaps loan. Towards this he would be happy to contribute a small sum, or some books, as a nucleus. The desirability of such a library is almost self-evident, since books on histology are for the most part either expensive, if recent, or comparatively scarce and inaccessible.

The PRESIDENT regretted the too little general use of the microscope, and that medical students had but little previous knowledge of natural history; and then—as in botany—high systematic work was often commenced at once, and the smaller but equally important plants neglected. Measuring and drawing he thought could not be too much insisted upon, and he fervently wished that instrument makers would provide a micrometer in lieu of much of the unnecessary apparatus usually placed in microscope cases.

THE LEGISLATION WHICH IS REQUIRED TO MEET THE CASE OF THE "HABITUAL DRUNKARD."

A PAPER upon this subject was read at the Social Science Association at a recent meeting by Dr. Alfred Carpenter, of Croydon, of which we present an abstract for the consideration of our readers.

The author said that three questions present themselves for discussion—1st. Is further legislation required or the control and management of the habitual drunkard; are not the powers already in operation sufficient for the purpose? 2nd. Are those powers capable of being used for his reformation? 3rd. If not, and new legislation is required, what direction should it take? and in considering these questions said that, according to his experience as a magistrate, acting in a thickly peopled district of greater London, they were inoperative as preventive measures, and had not the least pretence to be considered curative. He had seen the same persons charged with being drunk and disorderly, or drunk and incapable, as the case may be, and fined or sent to prison over and over again. After seven or fourteen days' imprisonment, they are discharged; in many instances, determined more than ever to be drunk as soon as they can.

He referred to the report of the Select Committee upon "Habitual Drunkards" which sat in 1872 for proof that small fines and short imprisonments were useless. The short time only increases the desire and sends him still further down the abyss from which, at present, there is no possibility of escape. The fact that a person has been sent to prison two or three times takes away from him all dread of detention. Whilst there he is relieved of the dyspepsia under which he always, more or less, labours; he does not care for food, he has plenty of water, and by the time he comes out his relish is restored, and he goes at the drink again like a giant refreshed, without the least particle of an idea regarding reformation or amendment of life. The maudlin sentiment which is occasionally met with in the early stages of recovery from a debauch is, in ninty-nine cases out of a hundred, evanescent, and has no time, under present arrangements, to become an integral part of a man's—still less a woman's—mental condition, and the last state of the victim is worse than the first.

The report of the Select Committee states distinctly that "there is an entire concurrence of all the witnesses in the absolute inadequacy of existing laws to check drunkenness, whether casual or constant."

The opinion of the Committee was most decided that "fresh legislation upon the subject was necessary, and that the law should be made more simple, uniform, and stringent."

It was proved before the Committee that drunkenness is the prolific parent of crime, disease, and poverty. That in some gaols as many as 75 per cent. of the criminals attributed their condition directly to drink; that at least 20 per cent. of the insanity recorded in Great Britain was produced by the same cause; and that more than one-half of the idiots which excite our compassion are the offsprings of drunken parents. It was shown as a natural consequence of these facts that increase of pauperism is inevitable, and that the children of drunkards are placed in positions of the greatest peril, with almost a certainty that they will be worse than their fathers.

The author then complained that Parliament ignored these facts, and allowed things to remain as they were, and said there is no legal remedy whatever for it; the only punishment capable of being inflicted is exposure, and this, because of its inoperative effect upon the victim, and its injurious action on the innocent relatives, every friend of the unhappy creature always tries to prevent. Still the course of the drunkard is downward, and only becomes

generally known when ruin stares the whole family in the face, or a suicide, or a homicidal act, has given evidence sufficient to prove that for a time at least the victim is insane.

He then pointed out that changes had been made in the law to meet the dangers incurred by railway travellers, and the carriage of explosive compounds, that garrotting has been put down by the lash, but that a disease which is only curable in its early stages, and which is more or less a skeleton in the cupboard of nearly every large family in the kingdom, is permitted to go on unchecked, and to send every year its tens of thousands into eternity, and leave as many others without hope, either in this world or the world to come, because it is supposed that an alteration in the law (which I shall show presently to be no alteration at all, but a rearrangement) might interfere with personal liberty: as if personal liberty were not interfered with, and had not been interfered with, in a hundred different ways, and in all ages, without the least serious injury to the commonwealth, when the exigencies of the State required it.

He then referred to the deputation which waited upon Mr. Cross in July last, which was headed by Sir Thomas Watson, and quoted Sir Thomas's speech in support of the necessity for a revision of the law.

Mr. Cross in reply stated that there were "great practical difficulties" in the way of an alteration, but did not detail them. The author then stated that communications had been opened with the Home Office by the Committee of the British Medical Association, whom he represented, and in reply Mr. Cross stated that the Government were not prepared to introduce any bill upon the subject this session, but that they would support any bill introduced by a private member. The author deprecated this course, and contended that the subject was important enough to demand that the measure should be a Governmont one. He then reverted to the difficulties which appeared to have appalled the Home Secretary. One objector asks, Do you propose to lock up every drunkard? if so you will require enormous establishments. The definition contained in Mr. Dalrymple's Bill disposes of this objection—"the person must be habitually incapable, injurious to himself or others, and unable to manage his affairs." The mere fact that a garrotter could be subjected to the lash did more to prevent garrotting than was effected by the actual infliction of the lash itself on the culprit. The knowledge that the habitual drunkard can be deprived of his personal liberty will assist in preventing many from rushing headlong down the path of destruction before they have entirely lost their power of self-control. It is to the class of drunkards who have lost that power to whom we wish to apply the proper remedy. The diagnosis of such cases is as well known to medical men as is the difference, which we now know to exist, between typhus and typhoid fever. The loss of self-control, the determination to have drink at all hazards and any cost, the changed mental state, the restlessness, the depression, the loss of all sense of duty, of truth, of honour and affection, are more or less present in every case, and tell the tale, when pointed out, but too clearly even to the uninitiated.

He then dealt with probability of cure within a reasonable time, and showed by the experience gained in other countries that there were good grounds for his argument, and after referring to the agitation which had been carried on in London, Birmingham, and elsewhere, read the resolution which had been moved by the President of the British Medical Association at the Edinburgh meeting:

"That excessive intemperance is in many cases a special form of insanity which requires special treatment, with a view, first, to the recovery of those affected, and second, to the protection and advantage of them and of society. That in the present state of the law such treatment is not attainable, and that it is desirable that legal provision should be made to render it attainable."

This resolution was supported by a gentleman from America, who detailed his experiences there, and was carried by acclamation in one of the largest meetings of the profession ever held in the United Kingdom.

The writer then urged that the question was not medical so much as public, that medical evidence should only be supplementary to the general, and given after it had been proved that the individual in question was addicted to drinking, that the fear of incarceration by designing relatives, which Charles Reade had done so much to promote, was a bugbear, and need have no real foundation if it was arranged that proceedings should always be taken before the local authority. He pointed out that the process need not add to public burthens, because if power to detain were given, such institutions as he advocated would be self-supporting. Let power be given to detain, and commercial enterprise will do the rest.

The last great difficulty is the "liberty of the subject." It is said that a man may gamble or waste his means with impunity if he so determines: why, say they, may he not drink away his inheritance? The answer is that the "drunkard's waste leads to a disease which may engender crime," and we have already adopted the rule that "we have a duty, as fellow-citizens, to care for one who cannot care for himself," and a duty neglected is sure to bring retribution on those who are parties to the neglect. Surely it is time to face that duty, and not to leave it longer unperformed.

He then said that further legislation was necessary, the powers now capable of being employed being totally useless for the reformation of the habitual drunkard.

We have to consider the subject under the head of—

(1.) Drink as a vice.

(2.) Drink as a disease which has been induced by indulgence in vice.

(3.) Drink as a disease inherited from those parents who did indulge in the vice.

He expressed an opinion that the disease ought to be prevented, like every other of its kind, but that as public opinion was not yet ripe for such a movement, they must be content with power to cure the disease after its establishment. The way was pointed out as only likely to be certainly successful if taken in hand at an early period.

The establishment of *Industrial Reformatories for Inebriates* has become a necessity. Dr. Carpenter hoped to see them take their place side by side with our Reformatories for crime and Industrial Schools for the children of criminals, and the destitute and wandering Arabs of our streets. Any one unacquainted with the subject, and reading the remarks of writers who are opposed to fresh legislation, would certainly conclude (as large numbers of people have done) that some vital change was contemplated in our statutes, some deadly attack upon the so-called liberty of the subject which must be steadfastly repelled. A reviewer says that the proposals contained in Mr. Dalrymple's Bill are so absurd that they do not demand serious attention. The writer concludes a powerful philippic against the Bill by asserting that if Parliament were to pass such a Bill the Court of Queen's Bench (now High Court of Judicature) would set it aside. "Happily," says the writer, "the judges of that court have both the power and the will to keep a check upon foolish legislation." He commended this conclusion to the attention of members of Parliament; it tells us pretty plainly that Parliament is not paramount after all, although the writer has missed the spot where power really lies. What if the threat which the prophet used against the people of Israel be realised in our own land, "that the prophets should prophesy falsely"—what if the "people should believe a lie?" their judgment be warped by the effects of neglected duty, and a Parliament be elected which should be imbued with the defective judgment which naturally belongs to the children of the inebriate.

It may be fairly asked how we should determine when the time for punishment has passed and the time for curative treatment arrived, bearing in mind the fact that the habitual drunkard has to be considered in two phases, namely, as giving way to a vice and as the subject of a

disease. If we are to take up the reformatory side of the question alone, there will not be much difficulty. The first part of the definition of habitual drunkards as contained in Mr. Dalrymple's Bill will suffice.

"A person shall be deemed an habitual drunkard who, in consequence of the habitual intemperate drinking of intoxicating liquor, is dangerous to himself or to others, or is incapable of managing his affairs."

It may be asked whether the definition does not imply that the person is a proper subject for a lunatic asylum. Truly it is an insanity, but it is not an insanity which can be properly treated in a lunatic asylum, it is a partial insanity which the law does not recognise as fit for lunatic asylum treatment. The proprietors of lunatic asylums are as glad to get rid of such patients as ever the patients are to discharge themselves, and the victims are seldom really the better for the short detention which the law now allows; like short gaol imprisonments they are useless for curative treatment. The evidence of all those who are qualified to give an opinion is against detention in ordinary lunatic asylums, as being alike injurious to both the lunatic and the dipsomaniac. The witnesses are all in favour of special houses for their treatment, inasmuch as the victims are not insane in the ordinary interpretation of the term except when under the influence or suffering from the effects of intoxicating drinks.

The writer then showed that the change required in the law was simply power to detain persons for a longer time than was given at present, to do for the drunkard that which was done for boy criminals, send them to reformatories.

A clause in the Licensing Act, 1872, gives power to the police to take proceedings against any one found drunk in places of public resort. Let this power be extended to individuals having a *bonâ fide* interest in the reformation of the victim, either as guardian, next of kin, heir-at-law, or head of the establishment in which he resides. Let the proceedings be always taken in a court of summary jurisdiction, and let them apply to drinking in private as well as public. Let the magistrates have power, if they think fit, to give costs against the pursuer if they are of opinion that it was not a *bonâ fide* case for inquiry, and let the magistrates determine the time during which the patient shall be under treatment, and we have nearly all the alteration of law that is required.

If to this power the clauses contained in the Reformatory Schools Act, 1866, be also combined, namely, those which give authority to the Treasury to contribute, power to justices to sentence, power to compel friends to contribute to the maintenance of the person, power to local authorities to erect local reformatories, power to guardians to contribute to their maintenance out of the rates, with penalties on those who assist inmates to break the rules of the establishment. And if with these are joined the clauses in the Lunacy Acts referring to visitation and control of management by justices, and also the appointment when required of a committee or person to act on behalf of patient during his treatment; we shall have all the machinery that is really required to frame an Habitual Drunkards' Bill, which shall at any rate be permissive, and will show in the course of a few years how far it may be prudent to travel on the road which tends to cure the disease alone. There should also be an arrangement by means of which a person should be able to be received in such an institution on his own petition, and machinery by means of which the visitors could revise the sentence if they thought fit, and very little else will be wanted to complete a permissive measure for dealing with the disease.

It has been argued that it would be very wrong to allow a person to commit himself to a reformatory for inebriates because he might change his mind. Let us bring this to the test of custom, premising that the committing authority would require evidence that the application was *bona fide*; would it be right to allow a man to withdraw from a contract because he had miscalculated his own power, or to give up the purchase of an estate because he found it convenient, or to compel a steamer, in which he had embarked for Australia, to turn back because he had altered his mind? He had determined that his was a proper case for treatment, and the committing authority had verified that opinion by proper inquiry, therefore there would be no reason whatever for allowing the plea of change of mind; those who advocate the *statu quo* on that ground show little knowledge of matter.

A Bill, therefore, containing a definition with half-a-dozen permissive clauses, and a reading of certain clauses from the Reformatory Schools Act, 1866, and some of the provisions contained in the laws relating to lunacy, and the requisite machinery would be forthcoming without any further change in the law.

The paper is an important contribution to the history of the subject, and we commend it to the careful attention of those interested in the future of the habitual drunkard.

LEGISLATION FOR THE HELPLESS.

(THE BLIND.)

No. II.

We very briefly alluded in last week's issue to the legislative enactments of a far-seeing and benevolent kind created by Parliament in favour of the blind and deaf and dumb. This commenced in 1832, when the Act 4 and 5 Wm. IV. cap. 76, was passed expressly to enable guardians to maintain and educate out of the rates all blind and deaf and dumb children up to the age of sixteen, without its being considered as parochial relief given to the parents. Thus a great rate-paid charity school for these afflicted children was created by the State. By subsequent Acts, first the 31 and 32 Vic., cap. 122, sec. 42, passed in 1868, which opened the widest possible field to the guardians, and enabled them to send blind children to either certified or uncertified schools, and it is almost incredible to believe that this power should have remained so long in abeyance.

Next by the Act 30 Vict., cap. 6, commonly called "The Metropolitan Poor Act, 1867," and entitled "An Act for the Establishment in the Metropolis of Asylums for the Sick, Insane, and other Classes of the Poor," additional legislative powers are given as to afflicted children and adults of all classes. Asylums also may be provided for the reception and relief of the sick, insane, infirm, or other classes of the poor chargeable in unions and parishes; but in this Act the term "asylum" means an asylum provided under this Act, and the expenses are to be taken out of the Metropolitan Common *Poor-Fund*. The mode of admission into the asylum shall be such as the Poor-law Board from time to time may order and direct. By sec. 38 the same authority may direct the guardians of unions in the metropolis to provide dispensaries where the sick poor may attend to receive *medicines* and *surgical appliances*, such as may be necessary for the proper surgical treatment of any case. It may be assumed that asylums "for the reception and relief of other class or classes of the poor" includes certainly the blind and other afflicted adults, and possibly also the children of these classes; but it is quite clear that the provisions for maintaining district metropolitan schools includes all children, not excepting any class of the afflicted, and that but for the accident of there being charitable institutions which deal with some of these children, all the indigent afflicted children would have to be dealt with by the managers of the asylums boards, who would have to supply schools with proper teachers and all necessary appliances of every kind. The same Act enables guardians of the poor to provide for the reception, maintenance, and instruction of *any adult* pauper, being blind, or deaf and dumb, in any hospital or institution established for the reception of persons suffering under such infirmities, and may pay the charges incurred in the conveyance of such pauper to and from the same, as well as those incurred in his support and instruction.

Thus it will be seen the guardians have full powers to deal with all poor blind and deaf and dumb adults, by sending them without *restriction as to cost* to any hospital or institution established for their reception. This Act, taken in connection with the "Metropolitan Poor Act, 1867," leaves the guardians of parishes or unions either to deal with any of the charitable institutions that will receive blind adults and instruct them both educationally and industrially, or send them to regularly established asylums.

If the guardians will not undertake this duty, then the Asylums Board may, under conditions to be prescribed by the Local Government Board, in the relief, maintenance, and management of the afflicted classes. Charitable institutions, therefore—the blind, deaf and dumb, &c.—are to a considerable extent doing the work of the Poor-law, whereas they might if they would insist on payments being made by guardians, and thus materially relieve their own charitable funds from much unnecessary outlay, and employ them more usefully in the relief of cases not coming under the provisions of the Poor-law. It is in some sense incumbent upon them so to do, seeing that since the passing of the Metropolitan Poor Act the voluntarily supported charitable institutions have been assessed to and do now contribute out of their funds very largely towards the maintenance of the poor.

By "The Poor-law Amendment Act," of 1844, 7 and 8 Vict., cap. 101, the Local Government Board may combine unions throughout the country and establish schools for all classes of afflicted children. The guardians have also large powers of boarding-out children, so that they may be near the schools, if not inmates. The most comprehensive Act, however, was passed in 1870 for the general education of all children, 33 and 34 Vict., cap. 75, and which requires School Boards to provide for the education of all children, and the guardians may pay the fees, or the School Board remit them. School Boards may also establish out of the Common Fund industrial schools, or send children to existing industrial schools. The experiment of educating the blind at ordinary "sighted" schools has been tried with perfect success both in Belgium and in Scotland. The beneficial results of the development of this system of instruction for the blind cannot be overrated.

It is high time to consider the effect of this mass of legislation, both on the general question of educating and caring for the blind and other afflicted classes, and in the numerous existing institutions which were created at a time when no legislation upon the subject existed. It must be seen that if practical effect were given to this legislation no inconsiderable amount of voluntarily subscribed funds would be set free for the further help of the multitude who are knocking in vain at the doors of the institutions. In fact, if the powers already granted by the Legislature were duly employed, they would render existing charities so far independent that they might safely abandon the voting and canvassing system, and which inflicts greater hardships on the blind than on many other of the afflicted classes.

The social disabilities of the blind attracted the attention of the "Charity Organisation Society," and last year a committee was appointed "to consider what more could be done to promote the welfare of the blind, and especially their industrial training." From this report we learn that in 1871, when the census was taken, there were 2,890 blind in the metropolis, of whom 292 were under 15 years of age, 991 over 15, and 1,607 above this age and under 50. In the United Kingdom there are upwards of 30,000 blind, of whom 10,000, at the very lowest calculation, are capable of being trained and rendered useful members of society. Nevertheless, not 800 of them have either been trained, or are engaged in any kind of profitable pursuit. Where, then, may we ask, are those thousands of blind people, of whose existence the census made us aware. The reply is that, with the exception of those in workhouses, the greater portion of them are thrust out of sight by mistaken charity, and made to dwell in lonely corners of the earth, there concealed from view, and unable to cope with the sighted world. "They exist to suffer, and to die without having lived."

We have shown how inadequately charity has attempted to deal with ever increasing numbers of the blind, and what a small percentage of them receive any of the benefits for which such earnest appeals are constantly made to the public. We have shown, too, that there is no legal exclusion of the blind from any of the benefits of education, and therefore, as their education is more expensive, there is all the more reason for their receiving the same grants as sighted children. It is indeed lamentable to observe in connection with this afflicted class the utter neglect of young children. Hitherto hardly any efforts have been directed towards the instruction of infants. That the general training of the young should be begun as early as possible, almost from very infancy, is obvious. The early education of sighted children is insisted upon by the Legislature, and in the case of the blind should be made compulsory. They should be sent to ordinary elementary schools, where they should remain until they are 15 years of age, or fitted to commence their industrial training, which should be of a thorough character. The experiment of educating the blind at ordinary schools has been tried during the past seven years, both in Belgium and in Scotland, with perfect success. The excellent results of this mode of instruction has been amply illustrated, and therefore should now be generally acted upon, whilst, for both children and adults, additional training institutions and workshops are much needed, and should be at once provided. The latter should be conducted by experienced and competent managers or foremen, chosen, if possible, from amongst the blind, as they must feel a deeper interest in all that concerns their fellow-sufferers. As to the mode of admission to charitable institutions, it is perfectly clear that the voting system is quite inapplicable to the blind; indeed, such a system is little better than an instrument of torture, thoughtlessly devised for the increase of funds at the cost of the most helpless of the afflicted. The only possible mode of admission is by a process of election or special selection, after a careful comparison of the claims of the several candidates.

THE STATE AND EPIDEMIC DISEASES.

A MEETING of the National Association for the Promotion of Social Science was held on Monday, when a paper was read by Dr. Alfred Carpenter, of Croydon, "On the Right of the State to obtain early information of the appearance of epidemic or infectious diseases in a given district—ought the medical man to be the informer." Dr. B. W. Richardson presided on the occasion. In the course of his paper Dr. Carpenter remarked that the right of the State to have the earliest possible information as to the prevalence of infectious diseases in a given district could scarcely be doubted, yet at the present time there was no law by which the information could be gained until fatal cases had occurred, and the registrar of deaths gave the note of warning in his report to his superior officer. The state had a right to establish a proper quarantine whilst the mischief was in a nutshell, and whilst it might be limited to a single house in a district. Ought not a legislative enactment to be passed to compel medical men attending cases of infectious disease to immediately report the same to the medical officer of health of that district? The reports of medical officers of health in all parts of the country teemed with evidence of the desirability of such information being afforded to them at an early date; many of them made the suggestion that medical officers of health should be able to demand the information as a right from the medical attendant in the case. But it should be remembered that a great number of cases of infectious diseases were not even now placed under the care of recognised medical men. Of these cases, therefore, the medical officer of health would get no information. Thus a legislative enactment which applied

only to medical men in such cases would act very injuriously against the interests of sanitary perfection. The repression of disease would only act in the same direction as at present—viz., by making it still more difficult to get at the truth, and harder still to keep a district free from the chance of disease spreading in it by unsuspected channels. In the third place, such a piece of legislation would also be against the interests of the medical profession, by giving a bonus to unqualified practitioners. In the fourth place, a still greater objection was to be found in the fact that it would, to some extent, alter the feeling of mutual trust and confidence which ought to exist between the doctor and the patient. Let it be made incumbent, however, upon the parent or guardian, or the head of an establishment, to give immediate notice to the medical officer of health of the advent of infectious disease in a given house ; and let the medical officer of health have power to apply to the private medical attendant in a given case for such information as he might really require after the knowledge of that case had reached him. In such case the medical attendant furnishing a report should be entitled to a fee for it, and it should be obligatory upon the reporter to make a true answer to his interrogator. A regulation of this kind would provide for the immediate discovery of all infectious diseases, and thus would place upon the medical officer of health the responsibility of advising measures for preventing its further extension. Dr. Adam Scott read a communication from Dr. Egeling, of the Hague, stating that in Holland a double notice was given to the authorities of the existence of epidemic disease—one by the medical man, and the other by the head of the family.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, MAY 3, 1876.

THE MEDICAL COUNCIL.

The remonstrance made by us in unison with the *British Medical Journal* against the postponement of the Medical Council meeting until the dog-days would seem to have produced some result, for the assembling of the Council has been fixed for the 24th of May, an earlier date than was anticipated, but still almost too late for any effectual intervention in Parliamentary medical business. We hope that the appreciation of our reasons for suggesting an early meeting thus manifested by the President will lead him to fix the 1877 meeting in February or March at the latest, in order that the Government shall not be betrayed into dangerous medical legislation for want of the guidance which they have a right to expect from the Medical Council.

The Executive Committee met on the 23rd of March to fix a programme for the forthcoming meeting, and were engaged in the first place upon the organisation of the next series of visitations of examinations. This matter had been referred last January to a sub-committee, who have presented a report. The important points in their recommendations are :—1. That the visitations, whenever they may be commenced, shall be concluded within five years. 2. That one-half the visitors shall be members of the Council, and the other half extra-conciliate practitioners. 3. That their fees shall be the same as those paid to the members of the Council for attending the meetings. 4. That their duty shall be "to inquire into and report to the Council as to the efficiency of the examinations conducted by the several licensing bodies as tests of the candidates' fitness to obtain the respective qualifications."

This latter phrase would seem to signify that the visitors will be charged, to ascertain *not* whether the examinations of each individual licensing body are sufficient guarantees of professional competence, but rather whether they are such as to deserve the licence of that particular corporation. It would appear to convey that, if the visitors should find that the examinations of any body are good enough for the standard of education represented by the licence of that body, they will have no business to consider whether those examinations are good enough for the efficient practice of the profession.

The Executive also had before them a long correspondence in reference to a public vaccinator, whose certificate (duly recognised from the London College of Physicians, and obtained from St. George's Hospital) was rejected by the Local Government Board. It would appear that the Medical Council issued recommendations in reference to the teaching of vaccination, in accordance with which St. George's Hospital, amongst others, appointed an instructor in vaccination. He did not, however, apply, as others had done, for the recognition of the Local Government Board, and they therefore rejected his certificate of proficiency. The case is a hard one for the vaccinator, but he has no redress, and must take a fresh course of instruction from a recognised teacher.

A further correspondence in reference to the supply of the Medical Register to all registrars in England was laid before the Executive Committee. A difficulty has been found to exist in supplying registrars with the means of deciding from whom they should or should not receive certificates, and it has been proposed to supply each of them with a copy of the official list ; but the Registrar-General considers that the Treasury would not consent to such an expense as the distribution of 2,194 copies of the Register would entail.

The rest of the sitting was occupied by consideration of the replies of the Colleges to the visitors' reports, and the Committee adjourned until they meet immediately before the Council.

PRESCRIBING CHEMISTS.

The Medical Defence Association announces another raid on the prescribing chemists, and the Council of the Pharmaceutical Society have received a sort of unofficial challenge to the combat in the columns of the *Students' Journal*, which periodical, to a certain extent, represents the policy of the Association. The Council of the Pharmaceutical Society had taken up the cudgels for prescribing druggists, as they did for the adulterators, and had blustered about their solicitor, one of them boasting that he infringed the law every day in the week. In reply to this the *Students' Journal* says :—

"It is suggested that the Defence Association should make a grand *coup*, once for all, by marching straight against the councillor who boldly declared that, according to Baron Bramwell's ruling, he infringes the law every day. This case, the *Chemist and Druggist* says, would be defended with the utmost strength of the Pharmaceutical Society. No doubt the case of the councillor referred to will occupy the attention of the Defence Association in good time, if he continues to infringe the law daily ; meanwhile, if the Pharmaceutical Society is anxious for a trial of strength with the Defence Association, an opportunity will soon present itself, for we understand that proceedings are about to be taken against other prescribing chemists. As to the result we have no fear, the Pharmaceutical Society notwithstanding. If the facts can be proved, conviction must follow ; there can be no doubt as to the law, for cases without number have been decided, in which it has been clearly laid down that chemists have no right to prescribe for patients. They may sell any preparation or compound, and state that it is good for this or that disease, but it must be sold under its own name, be it 'paregoric,' syrup of squills, or lenitive electuary. When a chemist selects his own drugs, and puts up a bottle of mixture for a patient, he goes beyond what he is authorised to do."

We shall see whether the Pharmaceutical Society will, as they have threatened, defend the right of druggists to prescribe. We trust that they will, for in so doing they would help to remove any doubt which a prescribing druggist may still entertain as to his legal position, and would call public attention to the hourly assumption of medical functions by unqualified and incompetent persons. The funds of the Pharmaceutical Society could not be applied to a better purpose, and it will be for the benefit of the cause which the Defence Association has in hand that their David should conquer or fall in an encounter with the Goliath of the drug trade, and thus force upon the attention of the prescribing chemists that they are engaged in an unlawful practice.

DEATH FROM PRIVATION.

It is difficult to believe that death from privation can take place in London, yet from time to time we hear of such cases, and those cases are reported to be amongst deserving poor. Last week, an inquest was held upon a man named Robert Lloyd, a mechanic, who from ill-health had been unable to follow his employment. He earned a few pence a day by holding horses for cabmen, and by this means supported himself for upwards of a year. The money the man earned was insufficient to purchase the nourishment required to support life, and gradually the man became weakened by inanition, dying from failure of the heart's action, on a doorstep in Regent Street, in the daylight and in the presence of a multitude of passengers. A narration of these painful facts suggests carelessness and even cruelty on the part of the witnesses of this scene—yet no one is to blame. There are at the present time many individuals in London, both men and women, gradually undergoing a process of death from starvation. The men have been hard working mechanics in their time, and so far as age is concerned might be so now, but they are suffering from chronic rheumatism or other chronic diseases. Their disease does not completely prevent them from working. On warm days they get to light work, message carrying, holding horses, &c., and by this means earn a few pence or even a few shillings. The women are mostly the wives of men who have deserted them, some, of men who are undergoing a term of imprisonment for various crimes ; many of them have children. By ironing, charring, and other badly paid labour they earn a few shillings a week, and by this means obtain for themselves and their children not one half the amount of nourishment required to maintain health. Without fuel no fire can burn, and though a flickering flame may be visible for a time it must ultimately become extinguished. And thus it is with these poor creatures ; they grow thinner and paler, they do not suffer pangs of hunger, for they are inured to the condition of an empty stomach, but by degrees disease if any exist, gains ground upon them, or the debility of nervous exhaustion from insufficient nourishment, renders the them less and less able to perform the little labour that offers itself to them, and in the midst of their journey to the work they fall and faint. From that faint, recovery is impossible ; no vital force is there even by the aid of strong stimulants to again promote a muscular contraction, and directed by medical evidence a jury decide that death was caused by failure of the heart's action.

Thousands of such deaths occur annually, but if the individual has been seen by the parish surgeon no inquest is necessary and the case is never made public.

Now can such deaths be prevented ? The out-patient physicians and surgeons of our metropolitan hospital, the parish and infirmary surgeons and others see numberless cases which they know will almost surely succumb ultimately to "a failure of the heart's action," yet they are powerless to prevent it. They recognise the inutility of prescribing medicines but have not the means of giving the relief required.

The patients cannot claim and they very rarely get relief from the parish. They often will not ask it, for they see that many of their friends are in better circumstances than themselves, and the idea never passes through their mind that there is any possible way of improving their condition. If there were a special fund at every hospital for supplying food to out-patients at the discretion of the physician or surgeon, doubtless much good would result, but the whole matter requires to be more fully examined into by a committee.

The difficulty that surrounds the question of the proper administration of charity is enormous, but it is not this question we desire to open.

A *widow* a *deserted wife* or a *sick man* cannot support a family, and if nourishment is not forthcoming they must surely die. To discriminate between such cases and imposters would not be difficult, and to obtain an adequate

relief for this deserving section of paupers would be an easy and a pleasant undertaking for the philanthropists, and for the benevolent members of the several boards of guardians.

BIRMINGHAM SANITARY WORK.

THE Officer of Health of Birmingham, Dr. Alfred Hill, by his untiring energy and zeal, has at length succeeded in thoroughly arousing the Corporation into action, and the sanitary improvement of certain deplorable parts of the town is about to commence. The scheme brought forward is on a scale of magnitude never before attempted by any provincial town. It involves the expenditure of about two millions of money upon ninety-three acres of ground now occupied by the worst class of poverty-stricken dwellings. The Government is asked to sanction the outlay, and an inspector has been holding a court of inquiry on behalf of the Local Government Board. In this condemned part of the town of Birmingham the death-rate ranges from 28 to 97 per 1,000, whilst the average of other parts has been reduced to 22. There are on an average not more than four-and-a-half persons to a house and 200 to an acre, which is far less than in many parts of London, Liverpool, and Manchester, and clearly shows that a high death-rate is due quite as much, if not more, to the character and surroundings of the dwellings of the poor as to overcrowding. The determination come to by the Town Council to sweep away at once and for all the whole of the condemned property, streets, and courts, and rebuild and rearrange it on the most approved principles, is, in every way commendable and judicious. Although, as we have said, there is really no great amount of overcrowding, the wretchedly poverty-stricken condition of the property can scarcely be matched in the worst parts of London. The houses are so built that they stand in close proximity to the backs of other houses, or within a few feet of dead-walls, built without windows and insufficient room space, built over and close to privies, middens, and which leak and percolate into the water supply; in short, built under conditions in which light, air, ventilation, common decency, or any pretence to sanitary conditions are absolutely impossible.

Of 3,851 houses included in the area, no fewer than 2,258 are built back to back, and within a few feet of dead walls in front. The cubical contents of the living rooms of the houses in many of the streets contain only 900 cubic feet, or, in other words, they are about ten feet square and nine feet high. With regard to the provision of proper conveniences, to which reference was made in the Artizans' Dwelling Act, there are in the district 1,760 privies—that is to say, one privy to ten of the population, or two privies to five houses. In very many parts of the district they are much worse than is represented by this average. Of those privies there are, under rooms and workshops, at the present time 332; while 152 ashpits, containing refuse of all descriptions, and no end of abominations. The result upon the health of the district in this state of things is only what might be expected, and the death-rate proportionally high—higher indeed than in the worst parts of Whitechapel, where the death-rate reaches its highest point in London, for we learn from Mr. Liddle's report that in certain parts of his district—Aldgate, for instance, the death-rate varies from 38 to 59 per 1,000; and from Dr. Rogers, the Officer of Health for Limehouse, that the death-rate is 48 per 1,000, and here we have examples of a high death-rate due to, and associated with, overcrowding and a neglect of all sanitary precautions; and we find from the reports referred to that most of the houses in these districts are totally unfit for human habitation. The proposed scheme, then, for the improvement of the town of Birmingham is for many reasons of more than local importance, because if carried successfully into effect and without any excessive or immoderate outlay, the example must become contagious and extend to many other large towns, to the great advantage of the artisan classes throughout the United Kingdom. Without some such improvement for the dwellings of the labouring classes, it is in vain to look for their social improvement. As matters now stand, educational and philanthropic efforts are too often found practically useless, and daily experience shows that sanitary reform must go hand in hand with all other efforts for the improvement of the condition of the people.

INEBRIATE ASYLUMS.

WE have, on the occasion of Dr. Dalrymple's agitation of the question in Parliament, entered with warmth into his views in favour of legislative restraint of drunkards. We therefore think it right to give publication to an adverse expression of opinion by a very high authority. In a speech at Rugby recently, Dr. Bucknill said:—He believed drunkenness to be a fruitful cause of disease, but not in itself a disease; and he looked upon inebriate asylums as an unfortunate attempt to coddle drunkenness, and to patch up a wide and social mischief. Last year he was in America, and he visited many of the American inebriate asylums, and came to the conclusion that the gentlemen confined in them were generally rather proud of their position, and felt themselves interesting subjects of inquiry. As far as he could observe, they were under a very lazy and shameful pretence of curing a disease which did not exist by remedies which were not applied. The patients had only to walk outside the walls of the institution to the nearest liquor shop, and get as much liquor as they chose to buy, and they could take liquor into the asylum with them. A friend told him that he went into the inebriate asylum on Ward Island, for New York, and visited the rooms of four of these unfortunate inebriates, every one of whom was enabled to offer him a choice of spirits. He very earnestly hoped that the Rugby Association, and the great one to which it was allied, would set their faces against the view of drunkennees as a disease. Habitual drunkenness is not a disease, though it causes all manner of diseases; but in itself it is a vice, and ought to be treated as a vice. The habitual drunkard is a man who likes to drink whenever he can, and who can drink whenever he likes. Dr. Lees, confirming Dr. Bucknill's view, said he had made himself unpopular in this country and in the United States, by denouncing the dipsomaniac asylums spoken of by Dr. Bucknill as humbugs. He had the confession of a man at the head of one of them, that, after the lapse of fiv

years, 95 per cent. of the patients go back to their former vicious habits.

With the greatest respect for Dr. Bucknill's views, we do not see that his statement tells at all against the establishment of carefully inspected and well-managed inebriate asylums. The account which he and Dr. Lees give may possibly be quite true, and we suspect that, *mutato nomine*, the same facts might be stated with reference to some of the inebriate asylums at home, which are rather *cloacæ* for the disposal of irreclaimable social nuisances than establishments for the cure of dipsomania; but the failure to cure habitual drunkenness in an asylum from which the patient "had only to walk outside the walls to the nearest liquor shop and get as much liquor as they chose to buy, which they could take into the asylum with them," proves nothing.

Whether Dr. Bucknill calls dipsomania a vice or a disease is not very material. If a vice, it is one which, admittedly, is not capable of cure by any moral influences or even by the most powerful exercise of will in the patient; and although it may not be a disease, it produces diseased conditions which feed themselves, and are capable of no treatment but abstinence. Why shall we continue to refuse to exercise the only means capable of combatting this vice or disease? Until Dr. Bucknill can prove that total abstinence fails, and that there is no other remedy, he cannot establish his theorem that drunkards must be left to kill themselves, ruin their families, and occupy our jails, because their condition is a vice and not a disease.

As for the statement of Dr. Lees' informant, we simply don't believe it, if spoken of a well-managed inebriate asylum, nor do we at all sympathise with the policy of the teetotallers whom Dr. Lees represents, and who discourage the proposal to establish inebriate asylums simply because they will have nothing but absolute prohibition of liquor drinking. Like the contagious disease fanatics, they resist all palliatives simply because they cannot have a perfect remedy for the disease of drunkenness, and persons who proceed on such a principle are worthy of no confidence when a cure for a wide-spread and deeply-rooted rational vice has to be thought out.

We publish to-day an abstract of a sensible, practical, and exhaustive address on the subject by Dr. Carpenter. *Rem acu tetigit.* Only two questions—as it seems to us—admit of debate; first, whether, supposing restraint possible, it would cure a sufficient number of drunkards to make it worth while providing for it? and, *next*, whether the reform of drunkards is an object which would repay the community for the expense and social dangers of treating them as lunatics?

Notes on Current Topics.

The Holborn Rookery and Fever Den.

DURING the past week an inquiry has been held before a Commissioner appointed under the Artizans and Labourers' Dwellings Improvement Act, on the condemned area of the Gray's Inn Road rookery of the Holborn district. Dr. Septimus Gibbon, the Medical Officer of Health of the Holborn Union, soon after the passing of the Act, made an official representation to the Metropolitan Board of Works that a vast number of the houses in this part of the parish were unfit for human habitation, that diseases such as low fever and the preventible ailments of children—infants especially—indicating a low state of health among the population, were always prevalent, and that these diseases might reasonably be attributed to the narrowness and closeness of the courts, to want of light and air, ventilation, and proper and decent conveniences, that the evils complained of and the sanitary defects of the area could not be effectually remedied otherwise than by improving them off the face of the earth—that is, by rearrangement, reconstruction, and more breathing space. The area is one of the most densely populated in the metropolis, containing upwards of 600 persons to each acre of ground. There are 239 dilapidated tenements, occupied by 3,661 human beings, the majority of whom were labourers, costermongers, flower-sellers, fruit-sellers, beggars, and women of the worst character. Some were employed in a large factory near, Eley's factory, others were bristle-sorters, brushmakers, and a few printers, and the death-rate among infants is consequently very high—50 per cent. of the children born die under five years of age. Adding the workhouse deaths to those of this district, they amount to 31 per 1,000, while the mortality of the whole of the Holborn district 22·30, and as against that of the whole of the metropolis, 20 per 1,000. A great part of the population is Irish, and among whom fever, bronchitis, and pulmonary affections were very prevalent, and largely due to bad air, want of ventilation, overcrowding, and a disregard of all sanitary conditions—in short, so bad are the houses that some of them are threatening to fall down, and one actually came to the ground a few days since, and, as the Rev. W. Lockhart said of the district, "anything would be better than to leave things as they are." The Rev. E. Richardson, a Roman Catholic priest, said before he came there, in January of last year, "he did not know there were such habitations for human beings in England. In one room, so small that he could touch the walls when his hands were extended, a young woman and a girl sleep, in the same bed; they eat, drink, sleep, and live in the same room." In short, the details he gave of the place were perfectly revolting. We trust, therefore, the scheme for the improvement of this plague spot of the metropolis will be forthwith carried out in no niggardly spirit.

Diseased Animals.

A RETURN has been issued of diseased animals seized or detained at the various ports in Ireland. In 1875 the shipments were:—Cattle, 595,530; sheep, 918,082; and swine, 463,618. The number of animals seized or detained was:—Cattle, 4 for pleuro-pneumonia, for foot and mouth disease of cattle 74; sheep, 54; and swine, 147. There were 100 sheep affected with scab.

Death by Lightning.

YESTERDAY afternoon, at Battisford, near Stowmarket, a man named Knock was struck by lightning and killed instantly; he was running towards a barn at the time for shelter. His forehead was found to be blackened and his hair singed.

Kirkcaldy.

An alarming outbreak of typhus fever has occurred in the mining village of Kingseat, in the west of Fife. For a fortnight fever has been lingering among the inhabitants. but some days ago it increased rapidly, and on Friday last the number of persons attacked was about fifty, the majority of the victims being adults. The epidemic is assigned to impure water supply, samples of which are now being examined.

The South Kensington Exhibition of Scientific Inventions.

The Exhibition of Scientific Inventions, to be thrown open in a few days, extends to the south side of the buildings (known as the Exhibition buildings) around the Horticultural Gardens. It was originally intended to stop at the galleries on the western side, but further space has now been devoted to educational appliances, and in what was the centre of the refreshment rooms, will be shown objects relating to applied mechanics, consisting principally of the collection from the South Kensington Museum, supplemented by articles sent by private collectors. Amongst other curiosities the old "Rocket" has been brought over from the South Kensington Museum; and near it will be Papin's original steam-cylinder, sent from the museum at Cassel. There is also a large collection of Watt's models, brought from different parts of the country. In the next room are the models of Brunel's block machinery, and Symington's first engine and a set of excellent diagrams for teaching applied mechanics, an exhibition of lighthouse apparatus, which will include models sent by the French Government, Trinity House, and the Commissioners of Northern Lighthouses, so that the history of science in relation to lighthouses will be well represented. Passing through the room devoted to Mr. Frank Buckland's piscultural collection, the first room on the east side contains a fine show of magnetic and electrical appliances. One of the curiosities of the room which has been sent among the Post-office collection is the old five-needle telegraph instrument, which has an historical interest in that it was used to stop a murderer who had taken the train at Slough, and was stopped at Paddington when he alighted, this being the first time the electric telegraph had been used to further the ends of justice. The collection of geometrical and mathematical instruments is exceedingly good, and includes Sir W. Thomson's tide-calculating machine. The late Mr. Babbage's calculating machine will also be shown, and Gravasande's apparatus for demonstrating the action of centrifrugal force has been sent from Leyden. During the fortnight commencing the 16th of May, a series of scientific conferences will be held at South Kensington, and several *conversaziones* will probably take place in the building in the course of the season.

Professional Amenities at the Antipodes.

We take the following from the *Melbourne Age* of December 28th: "The result of the recent lithotomy operation by Mr. Beaney has been the engrossing subject amongst the medical men at the hospital lately. The other day Dr. Duncan passed some jocular remark upon the subject to Dr. Webb, who assisted at the operation. Dr. Webb felt annoyed and called Dr. Duncan a liar; that gentleman then slapped him on the face. Dr. Webb, feeling himself aggrieved, has appealed to the committee, but it is probable that the affair will be settled by mutual agreement."

Extraction of a Living Insect from the Ear.

The *Archives Médicales Belges* relate the following case: A little girl three years old put an insect, "*bête à bon Dieu*," into her ear. Sharp cries, agitation, convulsive symptoms ensued; injections of water were made without result. The physician then conceived the idea of asphyxiating the insect by means of chloroform; he dropped four drops of chloroform upon a small piece of cotton which he introduced into the ear. Immediately the child ceased crying and complained no further of any disagreeable sensation; the insect had become asphyxiated; an injection of warm water brought it away dead, and no further trouble ensued.

Dog's Milk for Children.

Dr. P. Luzun (*Bordeaux Médical*, No. 43, and *Gazette Hebdom.*, November 5, 1875) relates the particulars of three cases in which he employed dog's milk. In the first, a girl between six and seven years old, affected with rickets, who was unable to walk. Within twenty-five days she became vigorous and able to walk. He states that dog's milk contains as much again of butter as human milk or that of the cow, and seven or eight times more than that of the donkey. It is also of all milks which are employed, save that of the sow, the richest in casein.

The Value of a Man.

No animal works harder than man, and as a working or domestic animal man may be valued. Dr. Farr has made some curious and interesting calculations as to the value of the agricultural classes. The calculations are not made to correspond to the working years of man, but allowance is made for the infant and child, who though not able to work, are valued prospectively; and so again in old age, when the labour period is passed; and as an animal he consumes more than he produces, his value is considered a minus quantity. The calculations are based upon the Norfolk agricultural classes, in which county the infant labour is worth at the time of birth, £5. When he has survived the first dangers of infancy, and has advanced five years nearer the time at which he will become a productive agent, his price rises to no less than £56, and this again in five years more is something more than doubled. At the age of twenty-five years he has attained his *maximum* value, £246, and he declines afterwards steadily but slowly, down to £138 at fifty-five years of age, and £1 at the age of seventy. After this age he produces little or nothing, but still he consumes, and when he is eighty years old he is valued at minus £41.

Minimum Doses on Dispensing Bottles.

An Australian pharmaceutist indicates on the labels of jars and bottles the maximum pharmacopœial doses, which serve to warn the dispenser, should excessive doses be prescribed.

Nature's Scavengers.

A WRITER in the *Quarterly Journal of Science*, in an interesting article on "Nature's Scavengers," refers among a great many others to our old friend, the sexton beetle. He does not, of course, deny that this is a most efficient sexton, or that its work in that capacity is immensely useful in preserving the air from taint. On the contrary, he is emphatic in its praises, and gives one or two very remarkable facts about it. A single sexten, he says, has been known to bury a mole forty times its own weight, while four of them have been seen burying a crow, which would certainly exceed their united weights in a still higher ratio. Wherever this useful little member of society finds a small dead animal, or a part of one, it deposits its eggs in the decomposing flesh, and then digs away the earth below it and covers it over—a practice, say the old books, beneficial to itself and to the world at large. But, says this writer, this is only one of an extensive family who do not bury putrifying matter in which they deposit their eggs, and if the well-being of the insect and the benefit of the world at large is Nature's intention, why has it been denied to the greater number of Silphidæ? He adduces many facts which, "if fairly weighed, seem to show that the practice of burying filth is not a primordial instinct, but has been acquired in the course of successive generations, and has taken various developments in various groups."

Granular Effervescing Sulphate of Quinetum, and Nitrate of Iron and Quinetum.

MESSRS. YOUNG and POSTANS have introduced two preparations as above named. A teaspoonful of the granules contains two grains of sulphate of quinetum, and five of the citrate of iron and quinetum respectively. As bitter tonics, or as a pleasant means of administering a mild iron and bitter tonic, the preparation will be found extremely useful. A teaspoonful of the sulphate of quinetum dissolved in half a wineglassful of water has a strongly bitter flavour, and so far as one can judge by the immediate effect of a dose, is as invigorating as a corresponding dose of quinine, but as a treatment of disease we cannot expect that invaluable *drug* to be replaced by the questionable salts of quinetum.

Prolonged Baths and their Action.

IN a paper by Dr. Kisch, the value of prolonged baths, which seem to have fallen into disuse, is considered. By *prolonged* baths, the author means those "in which the patients remain for many hours or the whole day." He suggests that a trial should be given them at the various bathing establishments, and then discusses the uses of prolonged baths, both general and local. According to his views, prolonged baths—the temperature of the water being from 37° to 38° C. (98·6° to 100·°4 F.) are a very powerful means of calming excited and irritated nerves, of acting upon and promoting the secretions of the body, and finally of accelerating the healing of open wounds and ulcers. He has found them a powerful anæsthetic in hyperæsthesia and neuralgia; also in cases where the cutis has been removed. He has also found them of great service in promoting absorption and the casting off of the epidermis; they are a powerful agent in accelerating granulation and cicatrization; and finally, in acting upon *nutrition* generally, and causing the removal from the body of effete matter.

Somnambulism.

A SOMNAMBULIST residing at Bury, has recently died from a fractured spine, the result of sleep walking. On the Thursday morning his wife saw him leaving his bedroom, and immediately followed him, but before she could reach him, he stumbled on the top stairs, and fell to the bottom. This man had been a sleep walker for eighteen years. On one occasion he attempted to get through a window, and on another he endeavoured to push a child through a bedroom window into the street, but was fortunately both times prevented from effecting his purpose.

A Food Chart.

MOST of our readers are acquainted with charts of poisons and some other subjects that have been used for several generations, as surgery furniture, just as maps so often adorn the walls of offices. Dr. Locke Johnson, whose name our readers will remember as the author of some interesting articles in our past volumes, has conceived and carried out the idea of grouping the multitudinous facts about foods of all kinds into a table or chart, which may be hung up on the wall, or folded and kept at hand in a cover. The former plan is certainly the more convenient, as it can thus be referred to at any moment, and we can strongly recommend it as a useful adjunct to the library, surgery, dispensary, or reading room, although its rather unwieldy size, three and a-half feet by two and a-half or thereabouts, will be an objection to many. The labour involved in such an undertaking is, of course, great, and we congratulate the author on the completion of his work. In it the composition, alimentary value, rates of digestibility, adulterations, tests, &c., of the foods and beverages in common use can be seen at a glance; it cannot therefore fail to be of great value for reference, while the student will find it gives him, as it were, an abstract of the facts of chemistry and physiology which most concern him. With Dr. Letheby's book "On Food" and Dr. Locke Johnson's "Food Chart," the practitioner's library would be complete in this direction.

New Mode of Division of the Infra-orbital Nerve for Obstinate Neuralgia.

WE learn from *Lyon Médical* that, in a case of obstinate neuralgia, Dr. Letievant operated for its relief by cutting down on the anterior edge of the floor of the orbit, breaking open the superior wall of the infra-orbital canal, raising the nerve, separating it from the artery and excising a piece nearly four lines in length.

HER Majesty has been pleased to appoint to the most distinguished Order of St. Michael and St. George, Valerius Skipton Gouldsbury, M.D. Surgeon to Her Majesty's Forces, and now serving in the Gold Coast colony.

The Medical Society of London.

THE President and Council of the Medical Society of London gave a *conversazione* to the Fellows of the Society and their friends on Monday evening the 1st May. Before the rooms were thrown open, Professor Erasmus Wilson, F.R.S., delivered a very instructive oration on "The Progress of Cutaneous Medicine during the Present Century," and which elicited the hearty applause of his audience. Numerous objects of interest in art and medicine adorned the rooms. The President, Wm. Adams, Esq., exhibited an arrowhead, with a portion of the leg bone of the celebrated Captain Cook attached to it. Professor Tennant, some recently discovered fossil elephant bones found near London. Dr. Leared, old Armenian bronzes, and articles brought from Morocca. Mr. Napier, antique jewellery &c. Dr. Gordon, autographs of celebrated people and selection of coins and ivories. Dr. Jagielski, an original stethoscope by Laennec, &c. Mr. Jabez Hogg, a series of very beautiful specimens, pathological and physiological, prepared for him by Messrs. Cole & Son, of Everton, Liverpool; and Mr. John Browning, micro-spectroscopes and microscopes showing the absorption spectra of various tinctures and metallic substances, &c. Mr. Clover and Messrs. Barth apparatus recently improved for the administration of nitrous oxide and ether. Messrs. Tisley and Spiller, a new form of medical battery. Messrs. Barraud, photographs of eminent medical men, art manufacturers, &c. Altogether the objects exhibited were of varied and instructive interest.

Ziemssen's Cyclopædia.

WE have from time to time noticed the quarterly volumes of this comprehensive work, as they have appeared. There are now five out of the fifteen volumes out, volumes 1, 2, 3, 4, and 10. The one which has made its appearance this week is volume 4, a most important and valuable Treatise on the Diseases of the Respiratory Organs (croup, diseases of the trachea and bronchi, and diseases of the pleura), by Prof. Von Ziemssen, of Munich; Dr. Fraenkel, of Berlin; Prof. Steiner, of Prague; Dr. Riegel of, Cologne; and Dr. Fraentzel of Berlin. Translated by I. Burney Yeo, M.D., of London; A. Brayton Ball, M.D., and George M. Lifferts, M.D., of New J. Solis Cohen, York; M.D., of Philadelphia; and Edward W. Shauffler, M.D., of Kansas City, Mo. The publishers for Great Britain are Messrs. Sampson Low and Co. of London.

Condy's Ozonised Sea Salt.

A CRYSTALLISED salt bearing the above name, and intended to be employed as an agent in the preparation of an artificial or medicinal salt-water bath, has been forwarded to us for examination. So far as we have been able to test its qualities, we may say that it appears to answer its purpose, and will be found a useful addition to the morning bath. As the salt contains a certain proportion of permanganate, and is also alkaline, soap is unnecessary. Its full effects as a detergent are, however, obtained when all the colour vanishes from the bath.

AT the levee held on Friday last by H.R.H. the Duke of Edinburgh, on behalf of Her Majesty, Mr. W. Adams, F.R.C.S., the newly elected President of the Medical Society of London, was presented by Major Cadman.

THE new number of the *Langham Magazine* has an article on the Water Supply of London, which, although it contains nothing actually new, summarises all that is known in an able manner, and presents to those interested in the question the whole subject in a readable form.

THE twentieth anniversary dinner of the Royal Hospital for Incurables has just been held at the London Tavern, under the presidency of Mr. Philip Twells, M.P. At the close of the speeches, the secretary announced the list of subscriptions as amounting to over £1,600.

A CONCERT will take place at the Royal Albert Hall on Saturday next at 8 30 p.m., in aid of the German Hospital at Dalston. The great increase in the number of out-patients forces the authorities of this hospital to enlarge the accommodation and add to their buildings, which will entail an outlay, we are told, of something like £5,000 to £6,000. It is to help to meet this extra expenditure that the above-mentioned concert is to be given. The concert will, by special permission, be given under the patronage of H.I.M. the Empress of Germany, who will arrive in England on a visit to her Majesty the Queen in the course of the present week.

Diagnosis of Diphtheria.

AT a meeting of the Richmond Academy of Medicine, reported in the *Virginia Medical Monthly*, Dr. W. Parker referred to several cases under his care of sore throat in adults attended with whole patches as of false membrane about the tonsils and pharynx not succeeded by ulceration, and in which the patients did not exhibit the debility characteristic of diphtheria, but recovered immediately after the local application of turpentine. A discussion followed, from which it appeared to be the opinion that the cases were of a diphtheritic form. Other cases were cited in which the deposit disappeared in as short a time as twenty-four hours.

It is rather important that practitioners should be able to decide whether a case of sore throat is one of diphtheria or not, and it must be recollected that the appearance of the throat in diphtheria in its earlier stage closely resembles that of acute catarrhal tonsillitis. In the latter disease the secretion becomes thickened and opaque, white or yellow in colour, blocking the mouth of the crypts of the glands, and often spreading over the surface of the gland. This disease, as in the cases described by Dr. Parker, is readily cured by the application of almost any astringent lotion, and is of course not followed by ulceration, or by the characteristic debility of diphtheria. The cases described resemble acute catarrhal tonsillitis rather than diphtheria, and we have known such cases to have been reported of the latter disease in this country as well as in America. No matter how mild the case of diphtheria, the eruption would not disappear in a few hours, nor does the disease ever occur without marked debility.

THE ROYAL COLLEGE OF SURGEONS IN IRELAND.

LAYING OF THE FOUNDATION STONE OF THE NEW BUILDINGS BY THE LORD LIEUTENANT.

On Saturday, April 29th, the foundation stone of the new building was laid in the presence of a large and distinguished assemblage of ladies and gentlemen, at the College, St. Stephen's Green, Dublin. His Grace the Duke of Abercorn, Lord Lieutenant, reached the College at about a quarter to four o'clock, attended by Col. Bernard Chambertain and an aide-de-camp, and accompanied by the Right Hon. the Lord Mayor of Dublin. The vice-regal party were received at the entrance by Edward Hamilton, M.D., President, George H. Kidd, M.D., Vice-President, W. Colles, M.D., Secretary, and the following members of the Council: Messrs. Butcher, Rawdon Macnamara, Porter (Surgeon to the Queen in Ireland), M'Dowell, Ledwich, Walsh, Dr. Mapother, Dr. A. H. Jacob, Dr. P. C. Smyly, Dr. M'Clintock, Dr. Denham, Dr. Barton, Dr. Stokes, Dr. Chaplin, Mr. Tufnell, Mr. W. J. Wheeler, Dr. Cronyn, Dr. Wilson, Dr. J. Stannus Hughes, Secretary of Council, Mr. Brennen, Registrar, Dr. Barker, Curator of the Museum, Dr. W. H. Griffiths, Assistant Librarian. Professors Drs. Mapother, Bevan, Stannus Hughes, Little, Stokes, Wilson, Cameron, Macnamara, Cronyn, Minchin, Wm. Thornley Stoker, and Davy. Examiners: Drs. B. Wills Richardson, Stoker, Barker, O'Grady, M'Donnell, O'Leary, M.P., H. G. Croly, Thomson, H. Croly, Kirkpatrick, Roe, Davys, Malone, and Morton. All the staff of the College wore academical costume. A procession was immediately formed, headed by the mace-bearer carrying the college mace, and proceeded through the building to the piece of vacant land at the rear, where all the necessary preparations had been made for the laying of the stone, and where those who had been invited to witness the ceremony were assembled, the military band in attendance playing the national anthem. It may not be out of place here to observe that the buildings about to be erected are for the purpose of giving a new library, museum, curator's rooms, &c., as the space at present given up to these uses is not at all adequate to the increased amount of books and specimens in the possession of the College. The additions are to be carried out along York Street, in perfect uniformity with the present building, so increasing that cut-stone flank. The new library will be about 68 feet long by 32 feet wide and 18 feet high, with a pathological museum over, having curator's rooms, librarian's rooms, stairs, lift, lavatories, &c. The library, at the extreme end of the museum, will have cases from the face of the walls, and a window between each case, at each side of the building. The library will have a raised dais at the end, communicating with the new foreign library. An ornamental iron gallery will be erected in the museum, which will also be lighted from the roof. The apartments will be heated with hot water. All the proposed alterations of the library, museums, board-room, &c., will be *en suite*, so that one can pass from one room to another without returning the same way. The works, which are being proceeded with, are estimated to cost £5,000. Messrs. Thomas Hall and Sons, of Harcourt Street, are the contractors.

The Lord-Lieutenant having taken the place assigned to him on a raised dias in front of the foundation-stone,

The President of the College taking the mallet in his hand, and prior to presenting it to his Grace, addressing him, said:—

Fifty years have passed away since, with this mallet, your illustrious predecessor, Most Noble the Marquis of Wellesley, laid the foundation of these Museums, which we are this day called on to enlarge. It would be out of my province (even were I adequate to the task) to detail the startling events which have occurred, or to picture the clouds and sunshine which have passed during that epoch over our native land. With one phase of that history we are, however, closely and intimately concerned, and it is that which has brought us here to-day. The remarkable advance which has been made in every department of art, literature, and science within that cycle—wonder-working agencies, as steam and telegraphy—have bridged over the spaces which, for a time, separated the distant families of the human race; and have bound with the golden links of civilisation the nations of the earth into one harmonious unity. In this onward course medical science has not halted; but, carried forward on the surging tide of progress, find the halls, museums, and libraries which were sufficient for the requirements of 1825, totally inadequate to the accommodation demanded in 1876. The written history of our College shows that it has ever been alive to the necessity for improvement—not the fitful craze for novelty; not the restless thirst for change; but the onward march—steady, determined, and enduring. The earliest dawn of our existence may be traced, like many other great institutions in Ireland, to the grand principle of Christian charity. In 1776, in the reign of Geo. III., was passed an act to regulate those noble charities—our county infirmaries, by which it was enacted, that no one should be permitted to undertake the charge of the sick poor in those institutions until their surgical knowledge was tested by an examining board, composed of the Surgeon-General and the surgeons of Steevens' and Mercer's hospital. The initiative of protection to the public led up to the granting of our first Charter in 1784, which was renewed in 1828, and supplemented in 1844. A few years after the College was chartered, Parliament granted the Licentiates the exclusive right of holding the county infirmaries. This privilege we have to the present administered faithfully, and with advantage to the public; and we may point with pride to the infirmary surgeons, whom we have established in every county in Ireland, as men of learning, men of high social character, in whom the public have passed the most implicit confidence. Should Mr. Gibson, in the interest of his constituents, the Dublin University, succeed in inducing Parliament to deprive us of this privilege, I think we may fairly claim compensation of some kind for the loss of what was a source of income as well as prestige. One thing, however, we must demand with no uncertain voice—that if, as we believe, there are monopolies existing to the prejudice of Irish surgeons, they too shall be cut away. One of the most important grounds on which our Charter was granted to us was, to quote its words, "the providing a sufficient number of properly educated surgeons for our army and navy;" a duty which we have endeavoured to discharge to the best of our ability. A certain amount of chivalry and love of adventure has ever been a prominent trait in the Irish character, and therefore our young men gladly accepted military service, and we gave them every encouragement to do so; but a change has come—paramount above every other duty confided to us is the maintaining the honour and dignity of our profession, and the protection of the alumni. Expression of complaint, dissatisfaction, and regret, reached us from our army surgeons, scattered over every region of the habitable globe, and careful investigation showed that they were not without foundation. We care not whether the service is worked on regimental or unification principle. We regard not sentimental grievances. The colour of a feather, or the breadth of a ribbon, may interest the drawing-room surgeon—they have no weight with men of mind. But we do demand that the profession of the surgeon shall not be a badge of disgrace, that he shall hold the same status as his combatent brethren, a status which is conceded to him in the relations of civil life. Their roll of fame is, for the numbers, as full of heroic deeds of valour and self-denial—yet how few the decorations of honour, so dear to the soldier, conferred on them. We believe that some attempt is being made to improve their

condition ; and we would raise the voice of warning that, with the Irish surgeon, no tempting offer of mere money will ever outweigh a degraded position or diminished prestige. We want fixity of tenure, if I may be pardoned the expression. We want the warrants, once signed by her gracious Majesty, shall not be altered to the prejudice of those who accepted service under them. We would ask that members of a learned profession shall be relieved from duties which appertain to the orderly or the purveyor's clerk. We would ask that when the medical officer becomes broken down by over-work, by climate, or disease, that his sick-leave shall be more assimilated to that of his brethren in the service. We would ask that his rank shall carry with it all the appanages which it confers on others. Until these disadvantages are removed, we cannot hope for a contented, efficient, or prosperous department. And lastly, this College is entrusted with the solemn charge of regulating and controlling surgical education in Ireland ; and it has ever been its most anxious care to raise and maintain a high standard of qualification and examination, and was among the first to insist upon evidence of preliminary education, and for years has this College single-handed fought against the principle of down competition, which was so near making shipwreck of our profession in these countries. The proceedings of to-day are intended to advance the Irish School of Surgery ; for I am sure your Grace will be pleased to learn that the museums and library, nobly endowed with presentations by his Grace the Duke of Northumberland ; by John Kirby ; by Colles, Crampton, and with the past year by Dr. Bevan, memorials of the handiwork of Shekleton, Houston, Carte, and Barker, are available not merely for our Fellows and Licentiates, but also for our pupils, to whom we are endeavouring to afford the same opportunities for study and observation which exist so largely in the Continental schools. This question has a practical aspect. It may not be generally known how closely interwoven is the condition of the Dublin Medical School with the welfare and prosperity of our city. From 800 to 1,000 students settle in Dublin for the nine months of the year devoted to medical study, representing a very considerable influx of capital annually expended among our citizens. In conclusion, permit me, on the part of the College, to tender to your Grace our most cordial thanks for your kindness and condescension in honouring us with your presence to-day. Well do we know the self-sacrificing anxiety with which you promote everything calculated to improve the condition of Ireland ; but we also know that the cares of State and function of the high office which you so graciously administer, imperatively demand intervals of quietude and rest, and therefore it is that we will ever entertain the deepest gratitude for permitting us to trespass on your leisure. Your Grace will, I am sure, permit me to thank those ladies and gentlemen who have so kindly honoured us with their presence, and to assure them that this day shall always be regarded as a bright and auspicious one. We must regard this brilliant assemblage, composed of the fair, the learned, and the great, patronised by a distinguished Irish nobleman, the omen of lengthened prosperity to the Royal College of Surgeons in Ireland. (Loud applause.)

His Grace having assisted in the spreading of the mortar with a suitably inscribed silver trowel, the stone was lowered into the proper place, after which the Duke gave it three blows with the mallet, and said :—My Lord Mayor, Mr. President, ladies, and gentlemen—I can assure you it is with extreme pleasure that I have accepted the invitation of the President and Council of the Royal College of Surgeons in Ireland to lay the first stone of the new building to be added to an institution which has sent forth so many eminent men. (Cheers.) There is no part of the world in which the reputation of the surgery of Dublin has not made itself heard, and I feel that in laying the first stone of the new building we are only inaugurating a larger sphere for those great and useful works for which the College of Surgeons in Dublin has made itself so remarkable—(hear, hear, and cheers)—and that we are laying the foundation for an even wider and more extended reputation than it has alraedy so universally enjoyed. (Applause.) I now declare this stone to be duly laid. (Applause.)

The proceedings then terminated, and the company dispersed.

Correspondence.

MEDICAL ADVERTISING.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—The salutary effect of your articles "On Advertising Medical Works in the Daily Press" must be evident to most of your readers. The long list of gentlemen who were in the habit of thus leaving their cards with the public is now become a very short one, and "the dirty corner" is almost deserted ! There is another way, however, of "getting your name up," perhaps, a more objectionable form of advertising. I allude to the manner in which some of the special hospitals are conducted. These establishments have hitherto not received that attention from the medical press that they deserve. It is, therefore, I think, Sir, high time that the peculiarities of the management of these *unendowed* charities should be brought before the profession and the public. It seems, at first sight, strange that these so-called institutions "for the relief of the necessitous poor" should have sprung up so rapidly of late years, and should receive so much support from the public. But this is not so when we come to remember the cause and origin of their existence. An enterprising medical man takes a house (generally a very small one at first) and calls it, perhaps, The Uvula Hospital, or The Central Cerumen Hospital.

We shall soon hear of institutions for the whites of the eyes, or the excision of toenails, and of the Royal Corn and Bunion Charity !

The rooms, if possible, are opened by Royalty—may be by a great singer, or, at anyrate, by a public man. Subscriptions come in slowly at first, but through regularly advertising the number of patients suffering from these several distressing, but easily-curable, complaints in the daily papers Miss Soft is induced to send an annual subscription of a guinea, and Verdant Green, Esq., a Vice-President, a donation of ten guineas, which is very gratefully and very publicly acknowledged. With help of thit kind circulars are printed in extraordinary numbers, and are sent all over the kingdom, headed, of course, in large letters, with the names of the promoters—I beg pardon, the medical officers. More money comes in, more circulars are poured out, and the chief benefit, I am afraid, Sir, finds its way into the pockets of the hospital staff, consisting, as a rule, of the senior officer and a harmless assistant ! By this means the surgeon soon becomes a successful man, takes a large house *for himself*, drives his carriage, and may even start a medical paper, wherein he could run down his professional brethren, and puff himself to advantage. Surely all this is advertising with a vengeance. If the benevolent would be guided in some measure by the awards of the Committee of the Hospital Sunday Fund, these institutions would shortly cease to exist.

I enclose my card, Sir, not for publication, and remain,

Your obedient servant,

AN UNENDOWED SURGEON.

THE ACTION OF STIMULANTS—A QUERY.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Is it not a contradiction in terms when we say that stimulants lessen waste ? I fancy they only lessen elimination, allowing the products of waste to accumulate in the system instead of being excreted. Elimination *may be* a reliable measure of waste in health; it *must be* a fallacious criterion in disease. Are there truly any "*substances d'épargne ?*" When I read of the increased exhibition of power produced by taking coca, valerian, or to come down to more familiar stimulants, alcohol or tea, I think it an unscientific explanation to say these lessen waste. The greater the blaze the quicker must the fuel consume. Either, then, reactive exhaustion *must follow* after a longer or shorter interval, or possibly the waste of the tissues is utilised, as smoke is prevented by a thorough

draught; but that would imply increased oxidation, and I do not think tea or alcohol favours oxidation, but the reverse. It seems to me an interesting subject for discussion by those capable of throwing light on it.

I am, Sir, yours faithfully,
F. M. LUTHER, M.D.

Medical News.

Royal College of Physicians of London.—On Thursday last, April 27, the following gentlemen were admitted Members of the College:—

Bennett, Alexander Hughes, M.D. Edin., 18 St. George's Terrace, S.W.
Oliver, George, M.D. Lond., Harrogate.
Park William, M.D. St. And., 20 Endsleigh St., W.C.
Sangster, Alfred, M.B. Camb., Guy's Hospital, S.E.
Skerritt, Edward Markham, M.D. Lond., Clifton.
Smith, Richard Thomas, M.D. Lond., 21 Haverstock Hill, N.W.
Sturge, William Allen, M.D. Lond., National Hospital, Queen Square, W.C.

Admitted Fellow:—

Thomas Edmonston Charles, M.D. Edin., Calcutta.

On the same date the following were admitted Licentiates:—

Bott, Henry, St Bartholomew's Hospital. E.C.
Buckell, Ernest Hook, 6 Harrington Street, W.C.
Burton, Herbert Campbell, Lee Park Lodge, S.E.
Don, Arthur Gorbutt, 56 Porten Road, W.
Fowler, James Kingston, King's College Hospital, W.C.
Henley, Edward, Belgrave Hosp., S.W.
Horner, Arthur, St. Bartholomew's Hospital, EC.
Hutton, Edwin Rutherford, 87 Lever Street, E.C.
Llewellyn, Rees Ralph, 152 Whitechapel Road, E.
Makins, George Henry, Bethlem Hospital, S.E.
Newman, John Jepson, Guy's Hospital, S.E.
Pearse, Joshua Sydney, University Hospital, W.C.
Pratt, William Thomas Cassel, Newport, Mons.
Rogers, Thomas King, 186 Southgate Road, N.
Shadwell, St. Clair Brockway, Walthamstow.
Shann, Frederick, 42 Halsey Street, S.W.
Sloman, Herbert, Farnham.
Smyth, Spencer Thomas, 6 Tyson Road, S.E.
Swanwick, Eustace Maclean, Greenheys, Manchester.
Walker, Horace, 16 Tavistock St., Bedford Square, W.C.
Watson, Percival Humble, Sunderland.
Williams, Philip Henry, Royal Infirmary, Windsor.
Winckworth, Charles Edward, South End Road, N.W.
Winship, William Lionel, Newcastle-on-Tyne.

The following Candidates having passed in Medicine and Midwifery, will receive the College Licence on obtaining a Qualification in Surgery recognised by this College:—

Batchelor, Henry Thomas, 17 Bancroft Road, E.
Buckell, Leonard Martin, 14 Holford Square, W.C.
Collier, Herbert, Bohemia House, Turnham Green, W.
Makuna, Manikji Dosabhai, 85 Ladbroke Road, W.

University of St. Andrews.—The following gentlemen, having passed the required examination, obtained the Degree of Doctor of Medicine on April 21st.:—

Brady, George Stewardson, M.R.C.S.E., L.S.A., Sunderland.
Davis, Andrew, M.R.C.S.E., L.S.A., Swansea.
Dixon, Edward Livesey, L.R.C.P. Lond., M.R.C.S.E., Preston.
Dobie, William, L.R.C.P.Ed., L.R.C.S.Ed., Keighley.
Granville, Joseph M., L.R.C.P. Lond., M.R.C.S.E., London.
Millard, William J. Kelson, M.R.C.S., L.M., L.S.A., Brighton.
Miller, George, L.R.C.S.Ed., Edinburgh.
Pearse, Frederick E., M.R.C.P.Ed., M.R.C.S.L., Stow-on-the-Wold.
Penhall, John T., F.R.C.S., L.S.A., St. Leonard's.
Roberts, Bransby, L.K.Q.C.P.I., M.R.C.S.E., L.S.A., Eastbourne.

At the same time James Key, M.A. St. Andrews, received the Degrees of M.B. and C.M.

Royal College of Physicians of London.—The following is a copy of circular sent to the Dean of the Medical Schools on Saturday last:—"Dear Sir, I beg leave to request your attention to the subjoined regulation adopted at the meeting of the College, held on the 10th instant, and which regulation will come into force on October 1st next.—I am, dear Sir, yours faithfully, HENRY A. PITMAN, Registrar. 'That every candidate for the College licence be required to produce a certificate of having acquired proficiency in vaccination, signed by a teacher of vaccination appointed or recognised by the Local Government Board.'"

University of London.—The following Examiners for 1876-1877 were elected at the meeting of the Senate held on Thursday last:—*Practice of Medicine.*—Professor Wilson Fox, M.D., B.A., F.R.S., and Charles Murchison, M.D., LL.D., F.R.S. *Surgery.*—John Cooper Forster, M.B., and W. S. Savory, Esq., M.B., F.R.S. *Anatomy.*—George W. Callender, F.R.S., and Professor John Curnow, M.D. *Physiology, Comparative Anatomy, and Zoology.*—George J. Allman, M.D., LL.D., F.R.S., and Professor William Rutherford, M.D., F.R.S.E. *Obstetric Medicine.*—J. Hall Davis, M.D., and Professor W. S. Playfair, M.D. *Materia Medica and Pharmaceutical Chemistry.*—T. Lauder Brunton, M.D., D.Sc., C.M., F.R.S., and Professor Sydney Ringer, M.D. *Forensic Medicine.*—Professor Arthur Gamgee, M.D., F.R.S., and Professor Henry Maudesley, M.D. *Chemistry.*—Professor Roscoe, Ph.D., B.A., F.R.S., and W. J. Russell, Esq., Ph.D., F.R.S. *Botany and Vegetable Physiology.*—Rev. M. J. Berkeley, M.A., and Maxwell T. Masters, M.D., F.R.S. *Geology and Palæontology.*—Professor Edward Hull, M.A., F.R.S., and Professor T. Rupert Jones, F.R.S.

Vital Statistics.—From the Registrar-General's return we learn that during last week 6,271 births and 4,121 deaths were registered in London, and twenty-two other large towns of the United Kingdom. The mortality from all causes was at the average rate of 27 deaths annually in every 1000 persons living. The annual death-rate was 22 per 1000 in Edinburgh, 24 in London, 30 in Glasgow, and 34 in Dublin. The annual rates of mortality during the same period in the other large towns were—Norwich 19, Hull 19, Leicester 25, Portsmouth 26, Newcastle-upon-Tyne 23, Birmingham 26, Brighton 26, Leeds 28, Wolverhampton 23, Bradford 26, Sheffield 30, Plymouth 30, Bristol 22, Oldham 37, Manchester 34, Salford 35, Nottingham 23, Sunderland 19, and Liverpool 36. The annual death-rate from the seven principal zymotic diseases averaged 3·9 per 1000 in these towns, and ranged from 0·0 and 0·8 in Norwich and Newcastle-upon-Tyne, to 7·1 and 7·9 in Oldham and Portsmouth. Scarlet fever, whooping-cough, and measles, were somewhat fatally prevalent in Portsmouth; and in Oldham 5 deaths were referred to fever and 3 to scarlet fever. Ten more fatal cases of small-pox were registered within the city and borough of Manchester and Salford, not one fatal case occurred in London.

NOTICES TO CORRESPONDENTS.

☞ CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

READING CASES.—Cloth board cases, gilt-lettered, containing 26 strings for holding each volume of the MEDICAL PRESS AND CIRCULAR, can now be had at either office of this Journal, price 2s. 6d. The postal regulations not allowing the Journal to be stitched, these cases will be found very useful to keep each weekly number intact, clean, and flat, after it has passed through the post.

LECTURES AT THE BROMPTON CONSUMPTION HOSPITAL.—A useful course of lectures to students is announced by members of the staff of this excellent institution, to which we have great pleasure in drawing attention. Two series of clinical demonstrations will be delivered at 3 o'clock, each Monday and Wednesday, during May and June, that "On Variations in Cardiac Rhythm" by E. Symes Thompson, M.D., F.R.C.P., on Mondays, at 3 o'clock, beginning May 8th; the other series "On Clinical Types of Heart Disease," by I. Burney Yeo, M.D., will consist of about ten demonstrations, and will be given every Wednesday, at 3 o'clock, commencing to-day.

CONTAGIOUS DISEASES.—A petition to Parliament to render penal the wilful communication of any disease, whether infectious or contagious, lies for signature at 168 Piccadilly, London. The wilful communication of diseases will be a very difficult matter to define.

CONTRIBUTIONS TO THE ETIOLOGY OF NERVOUS DISEASES.

By Julius Althaus, M.D., M.R.C.P. Lond.,
Physician to the Hospital for Diseases of the Nervous System.

In a paper which I read in January last before the Royal Medical and Chirurgical Society on the prevalence and fatality of nervous diseases, I have endeavoured to fill up a hiatus which has existed up to the present time in our knowledge of the occurrence of the various diseases of the nervous system. For this purpose I have analysed the annual reports of the Registrar-General on the mortality in England and Wales from 1838 to 1871, which form a large storehouse of facts that are of the greatest importance for social pathology. The reports are, on the whole, wonderfully correct, and certain errors and omissions which I have discovered in them are perhaps inseparable from a work of such magnitude. The interpretation of the facts contained in them must to some extent depend upon the degree of confidence one may attach to the way in which the certificates of death have been filled up by medical practitioners; and we shall probably be right in assuming that the entries of more recent date are more correct and reliable than those which were made when registration was first commenced. This explains to a great extent why the first period of years which is included in my investigations differs in several striking respects from the subsequent ones, which resemble one another more closely.

Amongst many proofs for this I will only mention that the entries of old age as a cause of death have gradually diminished from 10.67 per cent. of the entire mortality, which it was in 1838, to 5.46 per cent. in 1870. Now it would be evidently wrong to assume that thirty-five years ago twice as many people should have died simply of old age without any disease than is the case at present; for this would show such a deterioration in the public health as is quite incompatible with a large array of other facts at our disposal. To my mind these numbers simply prove that thirty-five years ago medical men were in the habit of putting down old age more frequently and loosely as a cause of death than they are in the habit of doing now, when the search for disease is keener and more successful. Fortunately the groups of nervous diseases which appear in the Registrar-General's Reports have such striking and characteristic features that, on the whole, the errors under this head cannot, with the exception of the first few years, amount to any very considerable quantity.

I now proceed to give a somewhat fuller abstract of the paper to which I have above alluded than has as yet appeared in the other medical journals.

The following nomenclature has been adopted by the Registrar-General for the several diseases of the nervous system: 1. Cephalitis (meaning encephalitis, myelitis, and cerebral and spinal meningitis); 2. Hydrocephalus (meningitis tuberculosa) was only retained in this class until 1842, when it was transferred to that of tubercular diseases. 3. Convulsions (infantile eclampsia). 4. Apoplexy (cerebral hæmorrhage). 5. Paralysis (white softening of the brain, &c.). 6. Delirium tremens. 7. Tetanus (was expunged without explanation in 1858). 8. Chorea. 9. Epilepsy. 10. Insanity. 11. Disease (a kind of lumber-room in which everything has been thrown which cannot be registered under the foregoing headings, and includes the rarer forms of cerebral and spinal disease, and also diseases of the eyes and ears).

The first question which I proposed for investigation was whether the proportion in which nervous diseases occur was a steady one, and subject to certain definite laws, to which there are no or only apparent exceptions, or whether it varies perceptibly from time to time. For this I calculated the number of inhabitants, the entire mortality, and the actual mortality from nervous diseases for a period of thirty years, and came to the conclusion that the death-rate for nervous diseases had varied between twenty-six and twenty-eight for ten thousand people during six lustra, and that the mean percentage for thirty years was 12.26 of the entire mortality, the greatest discrepancy from this

mean being .28 on one and .42 on the other side—that is, less than one-half per cent. The proportion in which nervous diseases prove destructive of human life appears, therefore, to be a very definite one, and subject to a certain fixed law from which there are no or only apparent deviations. In a nation which peoples almost all the inhabitable regions of the globe, and which is, as it were, constantly on the move both outward and homeward, the habitual operation of such a law must always to some slight extent be interfered with. Men suffering from nervous diseases come home from the colonies either for medical advice or from a wish to die in their native land; or they leave this country in search of health abroad, where they find a grave. Zymotic diseases, which occur not at a steady rate, but in waves, carry off persons who might but for their intercession have died of nervous diseases, and thus may swell or reduce the entire mortality of the period. Anyhow, the common assertion that nervous diseases have considerably increased during the last decennia has been shown to be incorrect.

My second question was, *What rank nervous diseases occupied amongst the more destructive distempers to which mankind is liable?* The answer is, that zymotic diseases rank first amongst the fatal maladies, with 22.90 per cent. of the entire mortality, that tubercular diseases follow with 15.94, respiratory diseases come after with 13.00, and diseases of the nervous system occupy the fourth rank with 12.26. It was incidentally discovered that while tubercular diseases had steadily diminished, respiratory diseases had as much increased of late years. The first of these two facts I am inclined to explain by the increased wealth and prosperity of the nation, and also to some extent by improved methods of treatment; while the increase of respiratory diseases is accounted for by the great rise of the manufacturing industry in the country. Amongst these diseases bronchitis is by far the most important, and we know the important influence played in its production by the inhalation of mechanical irritants contained in the atmosphere. While new manufacturing establishments have been springing up everywhere, only little has been done to remedy the evils of smoky towns, badly ventilated mines, and dusty workshops.

My third question was, Whether the several diseases of the nervous system bear a certain definite proportion to the sum total of these maladies, or are subject to considerable fluctuations; and whether in particular paralysis and insanity, as has been commonly asserted, have perceptibly increased within the last decennia? I have shown that an *increase* has taken place, more particularly during the last ten years, for *cephalitis*, *apoplexy*, and *paralysis*; and this rise amounts for cephalitis to two, for apoplexy to four, and for paralysis to six per cent., as between the first and last period of five years tabulated. *Delirium tremens*, on the other hand, appears to be on the decline; for, although the minimum was registered in the first lustrum, the maximum occurred in the second, and was never again reached in any of the subsequent periods; while the last lustrum shows a particularly decided fall. *Chorea* has increased in fatality of late years; and the ratio of increase will be understood by saying that the number of deaths from chorea was in the last period of five years more that double that of the first, while the deaths from all nervous diseases were only in the proportion of three to two in the same periods. *Tetanus* has slightly increased, while *epilepsy* has somewhat diminished, and *insanity* has decidedly increased during the last ten years, inasmuch as each year taken singly shows a rise over its predecessor. The maximum of 1·54 was attained in the last year, while at a previous period the percentage had been as low as ·75. *Convulsions*, or *infantile eclampsia*, form by far the most important cause of death amongst the several diseases of the nervous system. In the first lustrum a maximum of over sixty per cent. was attained, since when a regular and decided fall has taken place, until it reached 42 per cent. in the last period. This large diminution in the mortality from convulsions has allowed a rise to take place for other diseases of the nervous system, and more particularly for apoplexy and paralysis, without causing a corresponding rise in the mortality from nervous diseases altogether.

The fourth question was, Whether nervous diseases are more frequent in large towns than in the country, and whether any influence of race or climate can be recognised? The commonly received notion that these diseases are more prevalent and fatal in the great centres of social, professional, and commercial life I have shown to be fallacious, for the mortality of London is the lowest of all divisions in this respect; that of the south-western counties is higher, and that for Wales is very much higher, viz., about five per cent. above that of London. That the nervous system should be more liable to break down in the fine and wholesome atmosphere of agricultural districts than in the close and foul air of the courts and alleys which abound in great cities seems to show that excess of manual labour is more exhaustive than excess of mental labour, and that the more nourishing and substantial food enjoyed by even the poorest classes in London as compared with their brethren in the country, more than compensates them in this respect for the advantages which the country affords as far as air and climate and the delights of rural pursuits are concerned.

Wales exceeds all English counties so strikingly in this respect that neither density of population, nor climate, nor difference of occupation, will account for the same, and we must therefore attribute it to the fundamental difference of race. The nervous system of the Anglo-Saxon race appears to possess greater powers of resistance to unfavourable influences than that of the Celtic race, and to be better able to bear rude shocks as well as the ordinary wear and tear of life with impunity.

The next point I have endeavoured to elucidate by my investigations is the influence of *sex* on the fatality of nervous diseases. The rate for both males and females has been remarkably uniform, and amounts for the former to 12·94, and the latter to 11·62, so that males are more liable than females to die of nervous diseases, to the extent of nearly 1¼ per cent. of the entire mortality from all causes. With regard to the several diseases of the nervous system, it is shown that *cephalitis* is more fatal to males than to females; that, contrary to what has been stated by almost all previous observers, females die somewhat more largely from *apoplexy* and *paralysis* than males; that the proportion for *epilepsy* is nearly identical; that *chorea* is more fatal to females than to males; that *delirium tremens* kills at the rate of eight men to one woman; that *tetanus* is rather more frequent in the male sex; and that women are more liable to *insanity* than men. *Convulsions* are greatly more fatal to boys than to girls; and the entire mortality for males amounts to 54 per cent., against 46 for females.

Age has a wonderful influence on the fatality of nervous dieases, and one that is far greater than that of sex. An immense maximum is attained in the first year of life, and the number of deaths from nervous diseases during the first five years of age is greater than that of all the succeeding ages taken together, viz., 25,000 out of a total of 48,000. From five to thirty years of age there is a lull; at thirty-five a rise is perceptible, which becomes large at sixty, and reaches its maximum at seventy; but this second maximum amounts only to one-tenth of the first maximum attained in the first period. The first maximum is owing to the fatality of convulsions, and the second to that of apoplexy and paralysis. For the influence of age on the other diseases of the nervous system the reader must be referred to the original paper, as it would be difficult to understand it without the aid of the original diagrams. This holds also good for the relations of the two sexes with regard to the influence of age.

The last point considered is the proportion of deaths from *delirium tremens in the different counties of England and Wales*. I have found that London heads the list by a long way; that when London is put at 100, the proportion in the counties is between 60 and 40, and in Wales only 27. As the number of deaths from delirium tremens is known to correspond very closely to the

amount of strong alcoholic drinks consumed by the population, it appears very significant that London, where nervous diseases are at a low ebb, should consume so much more alcohol than Wales, where these maladies are singularly fatal. The question therefore naturally presents itself, whether a large proportion of strong alcoholic drink is really always prejudicial for the nervous system, as has perhaps been too sweepingly asserted by many well-intentioned men of late years; whether whisky is really the "devil in disguise;" and whether alcohol does not in many instances act as a preservative against the invasion of nervous diseases? There are, however, as yet, no sufficient data at our disposal to enable us to decide this point.

After drawing attention to the difference between mortality from these diseases and their prevalence during life, and estimating the latter partly from published official documents, and partly from clinical experience, I have asked whether medical science which hitherto seems to have been almost powerless to favourably influence the mortality to any great extent, will have more chance of doing so in future, when our methods of treatment shall have improved, and become the common good of all grades of the profession? We may reasonably expect a further considerable diminution of convulsive diseases in the natural order of things; and when it becomes more largely known to the body of the profession with what safety large doses of the bromides of potassium and sodium may be administered to infants, a further great reduction of the mortality from eclampsia may be expected. The fatality of epilepsy has likewise diminished during the last decade, most probably under the influence of better treatment; and there is good reason to believe that it will be further reduced in course of time. Even for tetanus, recent researches on the action of hydrate of chloral in that disease seem to hold out a prospect of its becoming eventually more amenable to treatment, while chorea is known to kill but rarely. Paralysis, apoplexy, insanity, and cephalitis on the other hand, will no doubt always carry off large numbers of victims as long as the present conditions of our existence, with its passions and sorrows, its troubles and disappointments, continue.

THERAPEUTICS: INCLUDING THE PHYSIOLOGICAL ACTION OF MEDICINES.

By W. Handsel Griffiths, Ph.D., L.R.C.P.E.,

Licentiate of the Royal College of Surgeons of Edinburgh; Lecturer on Chemistry in the Ledwich School of Medicine, Dublin; Editor for the *Edinburgh Medical Journal* of the "Monthly Reports on the Progress of Therapeutics"; Corresponding Member of the Therapeutical Society of Paris; Hon. Member of the Ontario and Chicago Colleges of Pharmacy, &c.; Librarian to the Royal College of Surgeons in Ireland.

(*Continued from page* 112.)

ACIDUM CARBOLICUM.

In 1860 Lemaire drew attention to carbolic acid as a remedy, and Mr. Calvert also early investigated the applications of this substance. It has lately been brought prominently forward as an antiseptic by Lister (*a*), Pasteur, Sansom, and others. These writers contend that putrefactive changes are due to septic infusoria in the atmosphere, and that carbolic acid acts by destroying the life of these organisms. The recent experiments of Dr. J. Dougall with carbolised lymph would tend to prove that carbolic acid is not antizomotic. The local and topical effects of carbolic acid are more energetic than those of creasote. The former acts as a powerful stimulant and caustic to the skin, and when incautiously applied has not unfrequently caused gangrene. It may be laid down as a rule that the strength of topical applications of carbolic acid to wounds should not exceed one part of the acid to eight of water or to six of oil.

Carbolic acid is a potent antiseptic, and is extensively used to correct the fœtor of gangrenous and offensive sores. In the treatment of wounds it acts beneficially by avnrting the tendency to the formation of pus, preventing inflammation, moderating pain, and arresting hæmorrhage. Mr. J. Wood advocates the employment of sulpho-carbolate of zinc as an application to wounds, suppurating abscesses, after-operations, and in gonorrhœa and venereal sores (*a*).

Carbolic acid represses exuberant granulations, and acts as a stimulant to weak, indolent, and unhealthy ulcers. As a topical application it has been recommended in the treatment of necrosis, caries, carbuncles, diphtheritic surfaces, lupus, and cancerous sores. It certainly relieves the pain of cancer, and cases are recorded in which it appeared to have modified the disease. As a gargle in diphtheria, carbolic acid has been extolled, and in other affections of the throat and pharynx, as in ulcerations and enlargement of the follicles, pulverised solutions of it have ordinarily proved beneficial.

As to the anæsthetic effects of carbolic acid when locally applied, Dr. A. H. Smith (*b*) confirms the statements of Drs. Bill and Squibb; it renders the integument entirely insensible, but does not interfere with the capillary circulation. Prof. Erasmus Wilson uses it as an anæsthetic to diminish the pain produced by caustics in lupus, &c. Carbolic acid is sometimes used for the cure of soft hæmorrhoids, which it effects by corrugating the integument.

Carbolic acid aborts the pustules of cow-pox and small-pox, and a solution of it in oil (1 to 8) is greatly recommended by Dr. Scott, of Dumfries, as an application to prevent the pitting after the latter disease, and also in cases of gunpowder burning (*c*).

In malignant pustule Dr. Estradère successfully uses carbolic acid, both externally and internally. In arthritis of the knee, subacute adenitis, &c., Huter advocates parenchymatous injections of it.

The internal administration of carbolic acid should be regulated by its effect on digestion; it should always be given freely diluted. Irritability of the stomach and a red tongue contraindicate its employment.

Dr. Fuller and others have found carbolic acid to be of great service in cases of fermentative dyspepsia, even when charcoal has failed to afford relief (*d*). It will be found that ten or fifteen grains of sulpho-carbolate of soda taken before food will prevent flatulence occurring after meals.

In torpor of the bowels with offensive breath and in sarcina ventriculi, Kempster advocates its employment (*e*).

Anal injections of carbolic acid are of value in mucous diarrhœa of the large bowel, and Rothe recommends the internal administration of it in the treatment of diarrhœa and cholera (*f*).

Salkowski employs carbolic acid in the treatment of some cases of vomiting (*g*). A case of tænia is recorded in which the administration of two grains of the acid every hour caused the expulsion of the head and body of the worm on the second day. Lemaire gives clysters of carbolic acid for the cure of ascarides.

In hæmorrhagic ulcer of the stomach the administration of grain-doses freely diluted has proved efficacious in checking the bleeding. When given internally, carbolic acid can be detected in the blood; it is stated, however, that it undergoes partial oxidation into oxalic acid.

Carbolic acid powerfully depresses the circulation.

(*a*) For details as to the antiseptic method adopted by Professor Lister the reader is referred to his monographs and papers on the subject, or to an able summary in Professor Sydney Ringer's "Handbook of Therapeutics," 4th Edition, 1874.

(*g*) *British Medical Journal*, May 25, 1872.

Carbolic acid has been employed in the treatment of various affections of the respiratory organs. Dr. Carlos, of Bahia, acting on the supposition that the epidemics of whooping-cough in the West Indies were due to the spores of some fungus was led to give carbolic acid in such cases with marvellously successful results. In a recent communication (*a*) Dr. Robert Lee reverts to the value of inhalations of carbolic acid in whooping-cough, and in the journal containing this publication Dr. George P. Rugg writes claiming priority over both Dr. Lee and Dr. Burchardt, of Berlin, insuggesting the use of vapour of carbolic acid in whooping-cough. The latter writer prescribes the steam from a solution of one and a-half or two parts of the acid in 100 parts of water for inhalation thrice daily.

Dr. C. G. Rothe, of Attenburg, recommends inhalations of carbolic acid in phthisis, and he gives the following formula :—Crystals of carbolic acid and spirit of wine, two parts each ; tincture of iodine, one part ; distilled water, ten parts. Of this mixture from 25 to 30 drops are to be added to a tablespoonful of water for an inhalation.

Dr. Angelo Cianciosi (*b*) relates a case of suppurative pneumonia following a stab in which he injected into the pleura a solution of 50 centigrammes of the acid in 200 of infusion of cinchona with marked benefit.

In catarrh with offensive discharge, ozæna, nasal polypi, &c., Kempster gives inhalations of a solution of one grain of the acid in an ounce of water (*c*).

In gangrene of the lung the administration of carbolic acid has been found useful in Salkouski (*d*), Gärtner, Leyden, and others (*e*). Carbolic acid has the power of reducing animal heat, and it has hence been suggested that its employment would be beneficial in febrile conditions attended with excessive calorification.

M. Déclat recommends carbolic acid for the treatment of intermittent fever ; he injects subcutaneously 75 drops of a one per cent. watery solution four times the first day, three times the second day, and twice on the third day (*f*). M. Treulich states that in cases of intermittent fever in which quinine has failed, carbolic acid will often effect a cure. He gives as an average dose four grains in infusion of gentian, and he records eight cases in which there were large tumours of the spleen which were cured under this treatment (*g*).

After the administration of carbolic acid the urine becomes dark and smoky looking, presenting an appearance very similar to that in bad scarlatinal nephritis ; sometimes a deposit is formed not unlike altered blood, but it certainly is not disintegrated corpuscles. The dark matter is entirely derived from the drug, and is a form of indigo blue. The depth of colouration is no indication of the amount of acid present. It is said that the urine is coloured dark more frequently from the external than from the internal use of carbolic acid, a fact Ferrier attempts to explain by suggesting that the acid becomes oxidised in the former case before its absorption. On the addition of sulphuric acid to the urine the odour of tar is developed, and chloride of iron yields a beautiful blue colour. The urine in health contains a trace of carbolic acid. Carbolic acid sometimes causes the transitory presence of albumen in the urine (Waldenström). Neumann has shown that hyperæmia of the kidneys with separation of renal epithelium constantly occurs in dogs poisoned by carbolic acid (*h*).

According to Fuller, although carbolic acid causes the disappearance of lithic deposits, it does not act beneficially in gout or rheumatism (*i*). A case of diabetes successfully treated with carbolic acid is quoted in the *Philadelphia Medical Times* for Jan. 30th, 1875. Fifteen and a-half grains of the crystals were dissolved in an ounce each of peppermint water and distilled water, and of this a sixth part was administered night and morning. Drs. Ebstein and Müller also recommend carbolic acid in glycosuria ; they suggest that abnormal fermentation may in many cases cause or permit the occurrence of glycosuria (*a*). It may be here mentioned that although carbolic acid will prevent the fermentation of sugar, it is said not to have the property of preventing the conversion of starch into sugar or the decomposition of amygdaline.

Injections of carbolic acid have been suggested for the treatment of catarrh of the bladder. Berndgen uses in chronic eczema a solution of five parts of the acid in ten of diluted spirit and 120 of water ; this solution he applies every morning with a camel's hair brush. In acute eczema carbolic acid is injurious (*b*).

The foregoing solution has been found very useful as an application in psoriasis. Neumann gave carbolic acid internally in psoriasis, and found that it reduced the hyperæmia, but did not affect the thickening of the cutaneous tissue, consequently it proved more successful in the treatment of the acute than of the chronic cases. Zimmerhaus gives in psoriasis pills each containing three-fourths of a grain of carbolic acid ; he begins the treatment with the administration of six of these pills daily, and gradually increases the dose to twenty of the pills in the twenty-four hours ; by this treatment he usually effects a cure in from four to seven weeks (*c*). Dr. M'Nab recommends for the treatment of psoriasis an ointment consisting of one part of the acid in four of lard ; he applies this every night, and covers the part with gutta-percha (*d*).

By Hertel, of Copenhagen, Guntz, of Dresden (*e*), and by Salkouski, it has been found very beneficial in the treatment of prurigo.

Hertel finds that carbolic acid acts specially on two symptoms accompanying cutaneous affections, namely, itching and hyperæmia. The action of the acid in tinea and some other skin diseases is attributed by some dermatologists to its power of coagulating albumen, stimulating the skin, and excluding the atmosphere.

Dr. Edgar Browne recommends carbolic acid as an application for sweating feet (*f*). In skin affections of cryptogamic origin the acid has undoubtedly proved serviceable. In alopecia areata Dr. Watson uses carbolic acid successfully ; he employs a lotion night and morning consisting of one drachm of the acid to three ounces of glycerine ; in a case so treated the scalp was covered with abundance of hair in seven months. Dr. Prior, of Bedford, states that carbolic acid will cure porrigo favosa, and that for achorion Schönleinii it is the safest and surest parasiticide (*g*). According to Kempster, it effectually destroys acarus scabiei and pedicularis capitis (*h*).

Dr. J. C. Nott, of New York, records a case of a carbuncle aborted by carbolic acid ; an incision was made into the carbuncle, and cotton-wool soaked in the acid was inserted into the wound every day for a week. Other successful cases are also recorded.

In erysipelas, Dr. Murell advocates the topical use of carbolic acid, and he has obtained successful results in the phlegmonous form of erysipelas by hypodermic injections of the acid as proposed by Aufrecht (*i*). Dr. Hirschberg relates a case of traumatic erysipelas successfully treated by hypodermic injections of a two per cent. solution of carbolic acid (*j*). A lotion of one part of the acid to 100 of water is recommended in pruritus ani. It is also useful in pruritus pudendi.

Sponging the body with a weak solution of carbolic acid is said to drive away mosquitoes. With reference to its action on the nervous system, carbolic acid in excessive doses produces spasms, the severity of which is only equalled by those produced by picrotoxine or codeine, and which terminate in paralysis and death. According to Labbee, the convulsions produced by carbolicacid are rather epileptiform than tetanic, its special influence being apparently exerted upon the cerebellum and medulla oblongata.

In gonorrhœa an injection of twenty grains of sulphocarbolate of zinc in eight ounces of water, to be used two or three times daily, has proved satisfactory.

Dr. Lloyd Roberts, of Manchester, early drew attention to the efficacy of carbolic acid in the treatment of ulcers of the os and cervix uteri, and in chronic uterine catarrh. An outline of his mode of procedure is given in Prof. Ringer's "Handbook of Therapeutics." It may be here mentioned that the fluidity of the acid may be maintained by the addition of a few grains of camphor, as suggested by Mr. Weir, of Dublin. Dr. Greenhalgh recommends as a vaginal pessary ten grains of carbolate of lime made up with stearine to correct the fœtor of ulcerating cancer of the womb. For internal use Dr. Sansom recommemds the substitution of the sulphocarbolates for carbolic acid. These salts are devoid of caustic and irritant action, and are soluble in water; they may be given in doses of from 20 to 40 grains. The soda salt is the most efficient, then that of magnesia, then that of potash, and lastly that of ammonia. These salts are decomposed in the system into carbolic acid, which is given off in the breath, and sulphate of soda which appears in the urine. Dr. Sansom collected and preserved the urine of animals to which sulphocarbolate had been given. He found that after six months the urine had not decomposed; it is not unlikely, therefore, that the administration of these salts may be useful to keep the urine sweet in cystitis, enlarged prostate, paralysed bladder, &c. Dr. Brackenridge (*a*) speaks highly of the value of sulphocarbolate of soda in the treatment of scarlet fever. He agrees with Dr. Sansom that this salt acts internally in infectious diseases by disinfecting the disease germs within the body. Acting on this theory, he recommends the administration of sulphocarbolate of soda to persons exposed to the poison of scarlet fever, diphtheria, measles, &c., and he relates several striking cases illustrative of the value of this suggestion. He gives the salt in doses of from 5 to 30 grains three or four times daily, and even more frequently when it is well borne. Carbolate of quinine has been recommended as a medicinal agent by Prof. Bernatzik, and Brawn gives it in puerperal cases; by Duchek it has been administered in typhus and pyæmia. (*b*)

Bufalini suggests camphorated phenol as a substitute for carbolic acid, whether internally or externally, on the ground that it is less dangerous, and that its employment is not attended with the disadvantages of the acid. Many cases have been recorded of poisoning by carbolic acid, arising both from its internal use and from the external application of it to a raw surface. It gives rise to giddiness, nausea, a feeble pulse, delirium, coma, or collapse, and sometimes in severe spasms ending in paralysis and death. The post-mortem examination reveals a liquid state of the blood, and a pale and shrunken condition of the lungs. There is intense venous congestion of the brain and its membranes; and in Neumann's experiments on the lower animals he found that carbolic acid caused congestion of of the brain-substance, and fatty or granular degeneration of the liver in the lower animals.

Olive oil is stated to be the best antidote, but the combination formed by oils with carbolic acid tends rather to facilitate the absorption of the latter. The administration of albumen, which forms with the acid an inert coagulum, is unquestionably a better measure. Husemann considers that saccharate of lime acts more efficaciously, an opinion with which I am inclined to coincide.

Most authorities state that the treatment of a case of poisoning by carbolic acid should consist—first, of the immediate administration of emetics; but as the alimentary tract is rendered insensible by the local action of the poison, emetics are entirely inoperative and utterly useless. Without doubt, however, the stomach-pump should be used without delay, and plenty of milk and the reputed antidotes should be administered.

Carbolic acid is largely used to prevent stenches. When offensive gases are once formed they are not destroyed by carbolic acid as they are by chlorine or by permanganate of potash; carbolic acid can only prevent their generation.

The fact of venous congestion of the brain having been observed as a consequence of carbolic acid poisoning has led to the adoption by Dr. Moslen, of Griefswald, of venesection of the external jugular with a successful result.

DESCRIPTION OF A CASE OF COMPLICATED HARE-LIP.

By Frank Thorpe Porter, L.R.C.S.I.,
Demonstrator, Ledwich School, &c.

To those who take an interest in the subject of "Hare-Lip" the following case may be not undeserving of notice:—At an early hour this morning I was called to attend an artisan's wife, whom I delivered of a strong male infant. On examining the face of the little stranger, I noticed an extensive cleft in the upper lip. The cleft was single, an inch wide, and was inclined more to the left than to the right. There was a double cleft on left side of maxillary bone, extending through the alveolar processes, hard and soft palate. This cleft was divided by a thin lamina of bone in the vertical direction. The portion of bone embraced by the cleft on the lip was devoid of alveolar processes; the portion of bone which was cleft was not embraced by the cleft in the lip, but was more external to mesial line. Right anterior naris was imperforate posteriorly, the left was imperforate inferiorly, but opened into the right internally. The infant is in strong health, but is too young for operation. Both parents are healthy.

CASE OF PLACENTA PRÆVIA WITH RARE COMPLICATIONS.

By Hugh A. Davis, M.D.,
Medical Officer to Newport Dispensary and Union Workhouse, Co. Mayo.

The following case will not be devoid of interest.

On April 18th I received a visiting ticket to go to see a poor woman in my district who was very ill in labour. I immediately went to the patient's home, a little outside the town of Newport.

She is the mother of ten children, five alive and five dead, this being her tenth confinement. All her other confinements were natural. When I got there I discovered she had lost a considerable quantity of blood *per vaginam*. The midwife told me that about a quarter of an hour before I was sent for she (the patient) experienced a severe pain, followed immediately by a profuse discharge of blood; the bleeding ceased slightly for 15 minutes, when another pain came on, and a considerable quantity of blood and clots came away; she then sent for me. After asking the midwife a few questions, I made a digital examination to ascertain the state of the os uteri and presentation. The os was soft and moderately dilated. I found a complete placental presentation; no part of the child could be felt above. The hæmorrhage having nearly ceased, and as no pains were on, I thought it advisable to wait a little. So

thinking that labour-pains might set in naturally, I then plugged the vagina thoroughly with cotton wool, and gave some brandy, with one drachm of ætherial tincture of ergot. The patient rallied a good deal. I waited patiently by the bedside, when in about half-an-hour she told me she felt a pain, the severest she ever felt, accompanied with a severe bearing-down, and cried out that something had passed. I then made another examination, and found the plug completely expelled, and the right foot and right hand down in the cavity of the pelvis. I examined the limbs, and to my surprise found the funis twisted around the ankle, and lodged between the great toe and next, the funis being very thin, and no pulsation could be felt in it. I loosened the funis, and proceeded to turn. I had some difficulty in returning the hand, but found the other foot readily, which I brought down, and so extracted the child, making traction with pains which were well marked now. The child was dead. Having waited ten minutes for the expulsion of the placenta, and no sign of it coming, I introduced my finger and tried to bring it down by hooking it, it being caught by the os. As it would not come, I passed my hand through the os, and found a great part of it firmly adherent to the right side of the os tincæ, which I removed carefully, and just then, another pain coming on, both my hand and the placenta were forcibly expelled, the uterus contracting forcibly and permanently. I applied a pad and binder, and left her after the lapse of an hour. She is rapidly convalescing, and has not had a single bad symptom.

All efforts at resuscitating the child were of no use.

The following points are worthy of notice in the above peculiar case :—

I. The rare position of the funis, and no doubt consequent death of infant.

II. That no hæmorrhage occurred during the latter months of gestation till the morning of the 18th ult., on which she was delivered.

III. The adherent state of the placenta after extraction of infant.

Clinical Records.

A CASE OF AMPUTATION OF THE FEMALE BREAST.

By Wm. Henry Middleton,
Surgeon, Westmeath Infirmary.

Miss S——, aged 45 years, residing some miles from Mullingar, called on my father, William Middleton, sen., M.D., for his opinion on a "sore breast" from which she suffered. On his seeing it he pronounced it cancer, and said he would rather not give an opinion as to what ought to be done till she would have my opinion in conjunction with his. She accordingly acceded to this, and presented herself on the 8th September, 1874. She presented the following appearance :—A tall, delicate-looking female, with a sallow complexion, anxious countenance, and a quiet and resigned disposition. She stated that four years ago the disease first commenced as a sore nipple. It went on increasing, but not to such an extent as to alarm her, and consequently she said nothing to her friends. Laterally it had given her great uneasiness from lancinating pains, and at times hæmorrhage. She then openly confessed her state. On the breast being uncovered for examination, it presented the following appearance : A large open sore on the right breast, the nipple entirely destroyed, a deep chasm being in its place ; the edges of the sore were rugged, with the skin inverted ; the whole gland was atrophied, hard, and nodulated ; from the breast up under the arm extended a thick, cord-like process ; the lymphatics in the axilla did not seem to be in any way enlarged, at least they could not be felt. On giving our final decision, we stated what was for and against operation, and left it entirely to her own choice, at the same time telling her that it was our opinion that before very long the disease would again appear, probably within a year ; that the only benefit she might derive from operation would be a short freedom from pain and bleeding.

Under the above circumstances she chose the operation, which was accordingly performed on the 11th September, 1874. She was put under chloroform by my father, and I removed the gland in the usual way, having to take with me more of the skin than I would have done had ulceration not extended so far. I tore out the breast, which came away easily from all points, except where the cord-like process extended into the axilla, and which required great trouble and care to remove. The ulceration in the centre had extended through the pectoral to the rib, a portion of which I sliced off. She took the chloroform badly. After the breast was removed, judging from the previous history of the case, with the hæmorrhage she had suffered from, I expected to have a good many vessels to secure, but to my great surprise, notwithstanding the extent of surface laid bare, not a vessel had to be tied or otherwise secured. Lest hæmorrhage might occur with reaction, the surface was allowed to remain as it was with a towel thrown over it for six hours, and our patient carefully watched, at the end of which time the edges were brought together with silver wire sutures, and the wound dressed with pledgets of lint soaked in carbolic oil. The wound was dressed in the same way every second morning. She went home on the 13th of October, 1874, the entire being nearly healed. I afterwards heard frequently from her, when she told me that all was healed, that she was free from pain and all inconvenience, and had greatly improved in general health. Some months afterwards she presented herself again, when she appeared a totally different person to what she first was. She had grown fat and healthy-looking, had lost all the cancerous look which was so well marked in the first instance. One year and six months has now elapsed, and a short time ago I heard from her that our opinion was coming true, that the disease had again began to show itself in the edges of the cicatrices. In the above case there are a few remarks of practical interest—1st. The length of time the disease remained without becoming alarming to the patient ; 2nd. The length of time the disease was present in the system, to be afterwards followed by such favourable results from operation ; 3rd. Although the previous history of the case presented considerable hæmorrhage, and on one occasion dangerous hæmorrhage, and such a depth and extent of surface having to be removed, that not one vessel had in any way to be secured ; 4th. She was, as is usually the case, an "old maid ;" 5th. That the disease, although to every appearance thoroughly removed, reappeared in the usual time.

ROYAL WARRANT.—ARMY MEDICAL DEPARTMENT.

Victoria R.

Whereas we deem it expedient to alter the terms and conditions of service in the Medical Department of our Army ;

1. The ranks and rates of pay of the officers of the Army Medical Department shall be as follows :—

	Daily. £ s. d.	Charge Pay.
Surgeon-General	2 0 0	The Principal Medical
After 25 years' service	2 5 0	Officer of an Army in
,, 30 ,, ...	2 7 0	the Field consisting of
,, 35 ,, ...	2 10 0	10,000 men and upwards, £1 daily; of 5000
Deputy Surgeon-General	1 10 0	men and upwards, 15s.
After 25 years' service	1 12 0	daily; of less than 5000,
,, 30 ,, ...	1 15 0	10s. daily.
,, 35 ,, ...	1 17 0	Or the Principal Medi-
Surgeon-Major, on appointment ..	1 0 0	cal Officer of a Colony
After 5 years' service as such	1 5 0	where the number of
Surgeon, on appointment ..	£250 a year.	commissioned officers
	Daily.	and enlisted men is 1500
After 10 years' service	0 17 6	and upwards, 5s. daily.

2. The pay of officers shall be issued monthly in arrear.

3. The relative rank of the officers of the Army Medical Department shall be as follows :—(*a*) A Surgeon-General shall rank as Major-General, according to the date of his com-

mission. (*b*) A Deputy Surgeon-General shall rank as Colonel, according to the date of his commision. (*c*) A Surgeon-Major shall rank as Major, according to the date of his commission; after twenty years' full-pay service as Surgeon and Surgeon-Major, he shall rank as Lieutenant-Colonel, but junior to the latter rank. (*d*) A Surgeon shall rank as Lieutenant, according to the date of his commission; and, after six years' full-pay service as Captain, according to the date of the completion of such service.

4. The relative rank of these officers shall regulate choice of quarters, rates of lodging-money, servants, fuel, and light, or allowances in their stead, detention and prize-money, as well as allowances granted on account of wounds or injuries received in action, and pensions and allowances to widows and families.

5. Forage shall be granted to officers of the Army Medical Department for such number of horses as are necessarily kept by them for duty.

6. Admission to the Army Medical Department shall be by public competition.

7. Every candidate for appointment to the Army Medical Department shall possess two diplomas or licences, one to practise medicine and the other surgery in Great Britain or Ireland, and be registered under the Medical Act in force at the time of his appointment.

8. A successful candidate, who, having passed through a course of instruction at the Army Medical School at Netley, in military medicine, surgery, hygiene, and pathology, shall have proved, after examination, that he possesses a competent knowledge of those subjects, shall receive a commission as surgeon for a limited period of ten years' service on full pay. From the date of joining at Netley and up to that of passing his final examination, a candidate shall receive 5*s.* a day.

9. On the completion of ten years' commissioned service, unless the surgeon be specially selected for further employment in the Medical Department of our army, or, if he be unwilling to continue to serve therein, his services shall be dispensed with, and he shall be entitled to receive in lieu of all pension or retirement, pension for wounds excepted, the sum of one thousand pounds.

10. A surgeon of less than ten years' service, disqualified for duty by ill-health, certified by a board of medical officers to have been contracted in and by the service, may, at the discretion of our Secretary of State for War, be granted half-pay at a rate not exceeding 8*s.* a day if he have served five years or more, or 6*s.* a day if he have served less than five years, for a period not exceeding six months at one time.

11. At the expiration of that period of six months, if the surgeon be able to resume his duties, he shall be entitled to complete his term of ten years' service. If he be unable to resume duty, as certified by a board of medical officers, he shall be allowed, if he have not served five years, a further period of six months, without half-pay; at the expiration of which period, if still unable to resume duty, his services shall be dispensed with.

12. If the surgeon have served five years on full-pay, and be unable to resume duty as certified by a board of medical officers, his services shall be dispensed with, and he shall be entitled to receive, in lieu of all further pension or pay, pensions for wounds excepted, a gratuity at one of the following rates, viz.:—

If he shall have completed	9	years'	full-pay	service ...	£800
,, ,,	8	,,	,,	...	700
,, ,,	7	,,	,,	...	600
,, ,,	6	,,	,,	...	500
,, ,,	5	,,	,,	...	400

13. If a surgeon be unable to complete his ten years' service from any cause other than wounds or ill-health, certified by a board of medical officers to have been caused in and by the service, or reduction of establishment, he shall be allowed not more than six months' leave without pay, after which, if unable to resume duty, his services shall be at once dispensed with, and he shall have no further claim on the department.

14. If the services of an officer be temporarily dispensed with in consequence of a reduction of establishment, he shall be granted the rates of half-pay fixed by Article 10 until there be an opportunity of re-employing him, or, if he have served five years, he may retire from the service with a gratuity according to the rates specified in Article 12.

15. Every year it shall be competent for our Commander-in-Chief, on the recommendation of the Director-General of the Army Medical Department, to select, with the approval of our Secretary of State, a number of surgeons not exceeding six, who shall be retained in the service, and shall be promoted after twelve years' service on full-pay to the rank of Surgeon-Major.

16. All promotion from the rank of Surgeon-Major to that of Deputy Surgeon-General, and from the rank of Deputy Surgeon-General to that of Surgeon-General, shall be given for ability and merit upon the selection of our Commander-in-Chief, with the approval of our Secretary of State; and the grounds of such selection shall be stated to us in writing, and recorded in the department. In all such cases the amount of foreign service shall be expressly stated.

17. A medical officer retiring after full-pay service of twenty-five years and upwards, may, if recommended for the same by the head of his department, receive a step of honorary rank, but without any consequent increase of half-pay.

18. Good-service pensions shall be awarded to the most meritorious officers of the Army Medical Department, under such regulations as shall be from time to time determined by us, with the advice of our Secretary of State.

19. Six of the most meritorious officers of the Army Medical Department shall be named our Honorary Physicians, and six our Honorary Surgeons.

20. Medical officers shall have a right to retire on half-pay after twenty years' service. Medical officers of the rank of Surgeon-Major or Surgeon shall be placed on the retired list at the age of fifty-five, and all Surgeons-General and Deputy Surgeons-General at the age of sixty years.

21. Our Secretary of State may, when he shall deem it fit, employ Medical Officers on the half-pay list in special situations at such rates of pay, in addition to half-pay, as he shall from time to time determine; but such officers shall vacate their appointments on attaining the age of sixty-five years.

22. A medical officer who, having voluntarily resigned his commission, has subsequently been permitted to re-enter the department, shall not, except under very special circumstances, to be approved by our Secretary of State, be allowed to reckon his former service.

Service on the West Coast of Africa.

23. Service of medical officers upon the West Coast of Africa shall be voluntary.

24. Each year or portion of a year shall be allowed to reckon double towards retirement or towards the gratuities fixed by Articles 9 and 12, but not towards increased pay, provided that the officer shall serve at least twelve months on the West Coast of Africa.

25. For each year's service on the Coast, a medical officer shall be entitled to a year's leave at home, and for every additional period beyond a year he shall have an equivalent extension of leave.

26. Officers who may volunteer for service on the West Coast of Africa shall receive double pay while actually serving on the Coast.

Non-effective Pay.

27. A medical officer of more than ten years' service placed on half-pay by reduction of establishment, or on the report of a medical board in consequence of wounds or ill health caused in and by the discharge of his duties, or on account of age (under Article 20), shall be entitled to half-pay in accordance with the following scale:—

	Daily.
Surgeon-General, after 30 years' service	£1 17 6
,, ,, 25 ,, ...	1 13 6
,, ,, 20 ,, ...	1 10 0
Deputy Surgeon-General, after 30 years' service ..	1 5 6
,, ,, ,, 25 ,, ..	1 2 6
,, ,, ,, 20 ,, ..	1 1 0
Surgeon-Major, after 25 years' service	1 0 0
,, ,, 20 ,, ...	0 16 6
,, ,, 15 ,, ...	0 13 6
,, ,, 12 ,, ...	0 11 0
Surgeon, after ten years' service	0 10 0

28. The rate of half-pay awarded to officers retiring for their own convenience, after 20 years' service on full-pay, under Article 20, shall not exceed one-half of their full-pay at the time of retirement.

29. Every medical officer who shall retire after a service upon full-pay of twenty-five years shall be granted a rate of half-pay equal to seven-tenths of the daily pay he may have

been in receipt of when thus retiring on half-pay, provided he shall have served three years in his rank, or shall have served abroad for ten years in all ranks, or for five years with an army in the field. An officer of twenty-five years' full-pay service whose service falls within neither of these conditions, shall be entitled to only seven-tenths of the daily pay he was in receipt of prior to his last promotion.

30. A medical officer of twenty years' full-pay service, placed temporarily on half-pay on account of ill-health, may, however, be allowed to retire on permanent half-pay at the rates fixed by Article 27, if after one year on half-pay he shall be reported by a medical board to be permanently unfit for further service.

31. In all matters not specially provided for in our present Warrant, the officers of the Medical Department of our Army shalr be subject to the General Regulations for the Departments of our Army.

It is our further will and pleasure that the rules established by our Warrant of the 1st March, 1873 (as amended by our Warrant of the 23rd October of the same year), Article 19 of our Warrant of the 18th February, 1874, and by Warrant of 29th September, 1874, shall continue to be applicable to all officers now in the Medical Department of our Army; but that Articles 4, 11, 12, 14, 15, 16, and 20 of our said Warrant of the 1st March, 1873, shall be cancelled, and the following Articles shall be substituted in lieu thereof:—

4. (*a*) A Surgeon-General shall rank as Major-General, according to the date of his commission. (*b*) A Deputy Surgeon-General shall rank as Colonel, according to the date of his commission. (*c*) A Surgeon-Major shall rank as Major, according to the date of his commission; after twenty years' full-pay service as Surgeon and Surgeon-Major he shall rank as Lieutenant-Colonel, but junior of the latter rank. (*d*) A Surgeon shall rank as Lieutenant, according to the date of his commission; and after six years' full-pay services as Captain, according to the date of the completion of such service.

12. A Surgeon shall be promoted to the rank of Surgeon-Major on completing twelve years' full-pay service in our Army, if he be recommended by the Director-General of the Army Medical Department.

16. All promotion from the rank of Surgeon-Major to that of Deputy Surgeon-General, and from the rank of Deputy Surgeon-General to that of Surgeon-General shall be given for ability and merit upon the selection of our Commander-in-Chief, with the approval of our Secretary of State; and the grounds of such selection shall be stated to us in writing, and recorded in the Department. In all such cases the amount of foreign service shall be expressly stated.

20. Medical officers shall have a right to retire on half-pay after twenty years' service. Medical officers of the rank of Surgeon-Major or Surgeon shall be placed on the retired list at the age of 55, and all Surgeons-General and Deputy Surgeons-General at the age of 60 years.

We do further direct that when any officer now serving shall, under Article 20 of our Warrant of the 1st March, 1873, as revised by our present Warrant, be compelled to retire at the age of 60, he shall have added to his retired pay, as fixed by our said Warrant, such annual sum as our Secretary of State shall consider to be a just compensation for any net loss he may have incurred from the substitution of 60 for 65 as the age for retirement.

Until our further pleasure shall be made known, nothing contained in our present Warrant shall be held to change the existing system of promotion of the medical officers of our regiments of household troops.

Given at our Court at Windsor, this 28th day of April, 1876, in the 39th year of our regn.

By Her Majesty's command,

GATHORNE HARDY.

LONDON SCHOOL OF MEDICINE FOR WOMEN.

ON the 1st May the Earl of Shaftesbury distributed the prizes at the annual gathering at the Institution in Henrietta Street, Brunswick Square. The room, which is large, was crowded to excess, the visitors collecting in addition around the doors and windows. The statement of the Dean showed that the classes in the various subjects had been well attended since the foundation of the institution in October, 1874, and that every facility was afforded to female students to gain in the school a sound medical education, its only drawback being the necessarily somewhat prolonged curriculum. It had hitherto been found impossible to gain admission for the students in any hospital containing the number of patients requisite to enable them to comply with the regulations of the legally-constituted examining bodies, notwithstanding the strenuous efforts that had been made for the accomplishment of that object. At the present time, however, a complete medical education was open to women, if they could afford to attend the lectures at the London School and clinical studies at the Edinburgh Infirmary.

The question of admission of women to the profession had occupied three days' discussion at the meeting of the General Medical Council in June last, and it was finally decided—"That the Council are not prepared to say that women ought to be excluded from the profession." At the same time suggestions with regard to arrangements for the admission of women to the profession were submitted by the Council for the consideration of the Lord President of the Privy Council, "should it appear to the Government and the Legislature expedient that women should not be debarred from obtaining a legal status as medical practitioners in this country.

Since that time a deputation from the Governing Body of this School had waited upon the Lord President of the Privy Council, the Duke of Richmond, and had learned from his Grace that the Government have the matter under consideration, though his Grace would not declare a distinct line of action.

Whatever might be the termination of the movement to admit women to the medical profession, the Governing Body of the School could congratulate themselves that they had sent women missionaries, who had received a sound medical education at that school, among castes in India and Africa, where no woman was allowed to receive medical advice or assistance from a man; a fact which of itself was a sufficient excuse, if excuse at all were needed, for the medical education of women.

The successful competitors for prizes and certificates of honour were: Misses Shove, Clarke, Ker, Butler, Bartholomew, Waterston, Hammond, and Mrs. Hart.

The Right Hon. James Stansfeld, M.P., spoke at some length on the subject of the removal of the legal disabilities of women to practise medicine. As far as the legislative side of the matter went he thought he could bid the institution be of good cheer, and hope with assurance for a favourable end to their difficulties. But there were other serious stumbling blocks in the way that seemed at present more difficult of removal. Three ladies had proposed to present themselves for examination at the Royal College of Surgeens for licences to practise in midwifery. What had occurred? The examiners had at once tendered their resignations rather than undertake the duties of conducting their examination. So far for the prospects of the general question. He now came to the consideration of the special prospects of the institution. The executive committee had endeavoured to tide over a time of financial difficulties, and it was hoped they would yet be enabled to do so, but if necessary more funds must be sought. It was hoped that they would have been before this been able to announce the provision of sufficient hospital accommodation for the students, but hitherto, as they had all heard, the metropolitan hospitals had met their requests with closed doors. If they did not meet with better success, the institution would have to come to a standstill, for young women could not be expected to come up to study year after year, without any prospect of ever getting their names on the register.

Miss Jex Blake believed that the institution would compare favourably with any medical school in London, and remarked that though admission for the students had not been gained in any of the "qualifying" hospitals, they

were nevertheless not entirely without clinical study. She had full confidence that if funds were wanting the public would supply them if they were able to show a fair chance of success.

The Right Hon. W. Cowper Temple, M.P., and Mrs. Garrett Anderson spoke at some length upon a resolution that in the opinion of this meeting legislative movements should be taken to secure the removal of all existing hindrances to the practice of the medical profession.

In reply to a vote of thanks to the chairman, proposed by Dr. Chambers, and seconded by Lady Stanley of Alderley, the Noble Earl expressed astonishment at the opposition shown by some members of the profession to a step which he was convinced would do nothing but good. He referred to the gentleness and skill of women as nurses, and could see no valid reason why they should be shut out from following a useful and noble career.

PHARMACEUTICAL SOCIETY OF IRELAND.

The monthly meeting of the Council of the above Society was held at the College of Physicians, Kildare Street, on Wednesday, May 3rd, Sir Dominic Corrigan, President, in the chair. Dr. Whittaker proposed, and Dr. Collins seconded, the following resolution: "That steps be taken to bring before the notice of the Chief Secretary for Ireland the advisability of having the Pharmacy Act (Ireland) amended, so as to give power to the Council of the Pharmaceutical Society to register as druggists all at business on their own account in Ireland previous to the passing of the Act, and to confirm them in the rights they then enjoyed; and also to make arrangements for the future as regards the qualification of those who may wish to keep open shop for the sale of poisons and poisonous drugs, without the privilege of compounding the prescriptions of members of the medical profession." After considerable discussion the motion was put to the vote and declared lost. The Registrar was directed to write to the Chief Secretary urging the advisability of exempting pharmaceutical chemists from service on juries, in accordance with a motion to that effect passed unanimously by the Council at a former meeting.

ROYAL MEDICAL BENEVOLENT FUND SOCIETY FOR IRELAND.

A meeting of the Belfast branch of the above excellent and prosperous Society was held on Thursday, the 27th of April. Dr. T. H. Purdon, the President, occupied the chair.

Dr. Browne, J.P., R.N., Hon. Treasurer, submitted the financial statement, and intimated that some of the subscribers had not yet paid their subscriptions for the current year, and that the accounts must soon be closed, so as to forward the proceeds to the parent society in Dublin at an early period.

The committee were then occupied for some time in considering applications for aid from certain widows of deceased medical men, who had been resident in the counties of Antrim and Down. These were carefully considered, and grants recommended in proportion to the exigencies of the several cases. These recommendations were ordered to be transmitted to Dublin for confirmation at the annual meeting of the parent society, to be held in the Royal College of Physicians, Dublin, in June next, at which meeting the President, Dr. T. H. Purdon, and Dr. Arnold, are to represent the Belfast branch as deputies.

The Hon. Secretary then reported that an interesting communication had reached him from a lady who had been formerly a recipient of their benevolence, in which she desired to thank the committee for their past kindness, and to intimate that she would not further require the assistance which in the past they had so kindly afforded. (Applause.)

WEDNESDAY, MAY 10, 1876.

THE NEW MEDICAL WARRANT.

The long-expected Royal Warrant for the future regulation of the Army Medical Department has at last appeared, having been signed by her Majesty on the 28th ultimo. Its provisions remain as sketched by Mr. Hardy upon bringing forward his estimates for the current financial year. All officers entering the department from henceforth must enlist for a short service of ten years, after the expiration of which period *six* will be selected annually for promotion into the higher ranks, the services of the remainder being dispensed with with an *honorarium* of a thousand pounds "in lieu of all pension on retirement, pension for wounds excepted." If a surgeon have served five years on full-pay, and be unable to resume duty, as certified by a board of medical officers, his services will be dispensed with, and he shall be entitled to receive in lieu of all further pension or pay—pension for wounds excepted—a gratuity varying from £400 to £900, according to the time he has served. The pay of the young surgeon will commence at £250 a-year, with the quarters and allowances of his relative rank, and if unable to complete his ten years' service owing to any vice or misconduct upon his part, his services, if unable to resume his duty after six months' leave without half-pay, will be at once dispensed with. With reference to the six officers selected for advancement into the higher rank of surgeon-major, the highest rate of emolument attainable on the completion of seventeen years' service will be £450 per annum, and the usual allowances, except forage, which will be only given when a horse is necessarily kept for duty. The maximum pay of a surgeon-major is £36 10s. per annum less than obtainable under the present Warrant, £1 5s. in lieu of £1 7s. The pay of the higher ranks remains as before, and the stupid regulation still remains, making a surgeon-major of twenty years' service rank with but *junior* of lieutenant-colonels, instead of with lieutenant-colonels, as in *all other departments*. The candidates are to go through a course of

instruction at Netley, receiving 5s. *per diem* whilst there. Retirements of administrative officers are compulsory at sixty years of age, and these appointments are to be by selection as heretofore. After twenty year's service the retirement remains as at present.

With regard to the officers now serving, the administrative officers will rank as majors-general and colonels on appointment. Surgeons will be promoted upon the completion of twelve years' service if recommended by the director-general, and the rates of pay and half-pay will remain as at present. The principle of unification is finally adopted by the cancelling of clause 15 in the Warrant of 1873, viz., "The medical officer attached to a regiment or battalion shall remain with it, as a rule, for five years;" but as clause 5 is not abrogated, a medical officer, when temporarily attached, will have to take his choice of quarters regimentally, and pay subscriptions to the band and mess of a corps with which he will now have nothing in common. This regulation, so obviously unjust, must in time disappear.

If we read the provisions of this Royal Warrant aright, the probationary period passed at Netley upon 5s. a day does not count as service, as it did under clause 10 of the Warrant of 1873. We have thus sketched the principal points of interest in these new regulations. We should add that the examination for promotion is abolished. It has not been stated whether the £250 per annum of the entering surgeons is to be supplemented by the allowances given in that country.

This Warrant does not grant all that we would wish to see conferred upon the officers of the Army Medical Department; but it adopts a principle of professional unification which cannot but hereafter make the military surgeons more united, powerful, and free. Ten years hence the service will have become more consolidated, and to most of the young officers who may select to enter the service, and wish to continue as military surgeons, the six selection clause must become a dead letter, for the profession can resort to the same means to abrogate it which they have adopted whenever they have been obliged to support their comrades in the army. Having shown where this new Warrant might be amended with advantage, we are bound to confess that there are some good points in it, and some solid concessions. Being now a united body, the *rôle* of the department should be to sink personal opinions and antipathies for the common good which can only be advanced by unity of feeling and sentiment, and by supporting the professional head of the corps, to whom the younger officers now in the service owe a great deal more than they are probably aware of.

THE CONJOINT BOARD.

Our readers are no doubt by this time aware that, after long delays and various conflicts of opinion, the delegates of the English examining bodies have come to an unanimous agreement respecting the future constitution of the Conjoint Board. We hear, however, that though the delegates have been unanimous, some of the Examining Bodies have already commenced to throw out objections which may seriously affect the whole scheme. This board, should it ever be constituted, however, will have so much influence in moulding the education of all those who hereafter enter the profession, and there is so much to be said both for and against some parts of the scheme, that we may be excused for again directing attention to the subject.

It will be seen by the following table that the board will consist of the examiners from the College of Physicians, the College of Surgeons, the Society of Apothecaries, and the Universities of Oxford, Cambridge, London, and Durham. It will be seen, moreover, that there are as many as 52 examiners, viz.: 12 from each of the corporations, and 16 from the Universities; while a glance at the table will show the subjects on which the future candidate will be examined, and the respective number of examiners that the examining bodies will be allowed to appoint on those subjects.

	Coll. Phys.	Coll. Surg.	Soc. Apoth.	Univer-sities.
Anatomy and Physiology	4	4	0	2
Chemistry	1	0	3	2
Materia Medica, Med. Botany and Pharmacy	1	0	3	2
Medicine	3	0	3	4
Surgery	0	6	0	4
Midwifery	3	2	3	2

Now the first thing that must strike any one in looking at this scheme is the great number of members composing the board. We have not space to enter upon a statistical examination of the question; but, were we to do so, we are very much mistaken if we did not find that the number was larger than was warranted by the amount of work to be done. A very large majority—we might say nearly all—of those who have hitherto entered the profession have obtained their qualifications to practise either from the College, or from the Hall, or from both; and if twenty-four examiners have been up to the present time equal to the task imposed upon them, we cannot help thinking that many years will elapse before any of these fifty-two members of the Conjoint Board will find their duties very onerous. Nevertheless we admit that it is better to have too many than too few, and perhaps, to vary an old proverb, "in the multitude of *examiners* there is safety."

A far more serious objection may be taken to the omission in the above syllabus of certain subjects that have been always regarded as an important part of medical education. On looking over the table, it will be seen that no mention is made of Forensic Medicine, Therapeutics, or State Medicine. With respect to the two latter, we have no doubt that the framers of the scheme had very good reasons for omitting them. It is to be recollected that the examination of the Conjoint Board must be a minimum one, and that it is advisable not to divide the students' curriculum of study into more subjects than are absolutely necessary. Therapeutics has always been studied in connection with Medicine and with Materia Medica, and as far as the general practitioner is concerned there is no reason why it should not continue to be so. As to State Medicine, no one would question the propriety of making it a separate department of medicine at a time when so much attention is being devoted to public hygiene. But state medicine has only been recently recognised as a special department of

medical science, and in all probability state medicine will, before long, be only practised by those whose knowledge of the subject has been attested by special diploma.

On the other hand, we cannot see why the study of Forensic Medicine should be ignored. It has always and very properly constituted an important part of the examinations of the Society of Apothecaries, and it is to be hoped that it may yet form a part of those of the Conjoint Board. It may not be necessary, in the presence of our public analysts, to demand of the young practitioner a thorough and practical knowledge of toxicology, as, if he had such knowledge, it is very questionable whether his evidence in a court of justice would have much weight. No criminal would be hanged or acquitted on the strength of an analysis made by a local surgeon, and the verdict would be always guided by the evidence of those eminent toxicologists who have made the detection of poisoning a special study. But it is otherwise with a knowledge of the symptoms and treatment of the more common kinds of poisoning, and of those topics in forensic medicine that may be forced upon any practitioner the very first year he enters upon practice. Scarcely has he received his diploma before he may be called upon to recognise and to treat a case of poisoning by arsenic, to examine an infant suspected to have been murdered, or to decide whether certain wounds have been inflicted before or after death, by the deceased himself, or by some other party. It is plain, therefore, that even in a minimum examination a general knowledge of forensic medicine is almost as necessary to the general practitioner as a fair knowledge of midwifery or therapeutics.

We now come to a feature in the conjoint scheme which, although it may have given satisfaction to all who have watched the gradual improvement in the qualifications and status of the general practitioner, has nevertheless in certain influential quarters excited much unfavourable criticism. It has been thought that too much power is given in the above scheme to the Society of Apothecaries in giving it the right to appoint three examiners in chemistry, three in medicine, and three in midwifery. Great exception is taken to the fact that the Society should be able to appoint three medical examiners, whilst the College of Surgeons is without the right of appointing any; and that, altogether, so much influence has been given to a body which cannot claim to represent modern medicine. Considering what the Society of Apothecaries has done for medical education during the last half century, it would have been in better taste had nothing been said in disparagement of its claims to take a fair share in the conduct of the conjoint examinations; and it is to be regretted that any attempt should be made to create a prejudice against the Society in the minds of those very practitioners who have most reason to thank it for the good position they hold in the opinion both of the public and the higher ranks of the profession. It is quite true that chemistry is a subject of very great importance, and that it is "one of the foundation-stones of the science of medicine." But it is somewhat remarkable that this has only just been found out, and that the only licensing body whose share in the Conjoint Examinations on chemistry has been disputed is that which has all along, in its own examinations, consistently acted upon the principle of which we are now in the eleventh hour reminded, and which has all along attached more importance to this branch of science than all the other licensing bodies put together have done. But the fact is, there is very little use in cavilling about the respective share which the Corporations will have in the formation of the new board, inasmuch as they will have, individually speaking, very little influence in the conduct of the examinations. It is evident that if the powers vested in the Committee of Reference be as great as is generally reported, the new board will be a conjoint one only in name and in appearance. Virtually it will be an independent body. Its committee of reference will have the privilege of nominating all the examiners, while the only privilege of the licensing bodies will consist in selecting their examiners from among the nominees of the committee. What, however, is a sacrifice on the part of the corporations, may be a great gain to the public; and we may, in conclusion, remark that both the public and the profession may be congratulated on the progress that has now been made in the establishment of the one-portal system. It is to be hoped that this scheme will receive the sanction of the Medical Council at its forthcoming meeting, and that the example which has been set by the English examining bodies will be followed in other parts of the United Kingdom. With the one or two exceptions we have noted, the scheme is a good one. Of course no one would for a moment suppose that the present arrangements are final. Improvements may be made from time to time, as exigencies arise, or experience may suggest. And, with respect to the objections we made at the commencement of our remarks, the board may yet demand of its candidates some knowledge of forensic medicine. Hygiene may be made an optional subject; and therapeutics may come to occupy more of that place which has hitherto been monopolised by the dry details of materia medica.

Notes on Current Topics.

Westminster Home for Nurses.

Last week a meeting was held in the Jerusalem Chamber, Westminster Abbey, to consider the best means of giving effect to the suggestion of Lord Hatherley, made in a letter in the *Times* of the 21st ult., that the most enduring and appropriate memorial of the late Lady Augusta Stanley would be to place the Westminster Training School and Home for Nurses on a solid and permanent foundation, and associate her name with it. Lord Hatherley took the chair. The noble chairman read a letter from the Dean of Westminster, who referring to the charitable works of the late Lady Augusta, said there was none to which in her later years she devoted more time and trouble than that of establishing the Westminster Home for Nurses.

The Duke of Westminster sent a donation of £500, and the Speaker of the House of Commons, and Mr. W. H. Smith, sent £100 each. Lord Hatherley said that when

a building should be erected the Home would be in a large degree self-supporting, and would at the same time provide nurses for both rich and poor.

It was resolved—

"That it is the desire of this meeting that an enduring memorial should be founded to perpetuate the honoured name of Lady Augusta Stanley; and it is their opinion that such object may be best accomplished by associating that name with a work of beneficence originated by her, and in which to the close of her life she evinced an active and sympathising interest. They therefore suggest that means be immediately taken, in concert with the committee of the Westminster Training School and Home for Nurses, to obtain the funds required to place that institution on a solid and permanent foundation in association with her name, in such form as may hereafter be determined on by that committee."

The British Medical Association.

A SPECIAL general meeting of the British Medical Association was held last week in Birmingham, to decide the place of meeting in the autumn. After hearing a deputation from Sheffield, the meeting passed a resolution to the effect that, "having received so warm and cordial an invitation from the professional members of the association in the Sheffield district to hold the annual meeting in August next at Sheffield, this meeting recommends the committee of council to accept the invitation to Sheffield, and that the minute of the general meeting held in Edinburgh on August 4, 1875, be and is hereby rescinded."

Poisoned through Carelessness.

THREE men, *employés* of Messrs. May, costumiers, Bow Street, sent for beer in a jug which had previously contained a mixture of cyanide of potassium used in cleaning stage armoury. After drinking the beer the poison soon took effect, and two of the men were taken to King's College Hospital, where one of them died. A second is still in a precarious state.

Sewage in all Surface Wells.

DR. WHITMORE, the Medical Officer of Health in Marylebone, in his monthly report, refers to the dangerous condition of the water taken from many pumps in the district.

With one or two exceptions all the pumps in the parish are polluted with sewage, and it is certain there are no means of purifying them. Most of the pumps under the control of the vestry have been removed, but there are still no inconsiderable number of private pumps in stables and such-like places, drawing their water from similar sources, and the water from which is used for drinking and domestic purposes. It is useless to explain to the owners of these pumps the risk and danger they incur from drinking this water; they at once point to its clear, cool, and sparkling condition as evidences of its purity, and refer triumphantly to the circumstance that for many years they and their families have drank it without having experienced the slightest ill effects from it.

Doubtless such is the case, and as it is substantially proved that the water contains sewage, it goes far to confirm the opinion that certain diseases are not produced by drinking polluted water, unless the matter by which the water is polluted contains the specific germs of those diseases. Whether typhoid fever can arise *de novo*, or whether it is necessary that its germs should be present in [the water in order to produce that disease, is a matter of but little importance so far as the necessity for closing surface wells is concerned; for, apart from the loathsome idea of drinking water polluted with sewage, sewage matter containing the zymotic poison may at any time percolate into a surface well, and so bring about an epidemic of the disease, the spread of which might be indefinite.

Registration of Women.

AT the last quarterly meeting of the Bradford Medico-Ethical Society, held on the 28th ult., the following resolution was unanimously carried:—"That the best thanks of this Society be given to Dr. Barnes, Dr. Farre, and Dr. Priestley for their manly determination in resigning their seats at the Board of Examiners for the licence in Midwifery at the Royal College of Surgeons, rather than take any part in admitting to the Medical Register persons who are not also legally qualified in medicine or surgery."

It is curious how actions directed towards a given end sometimes bring about a result diametrically opposed.

The Council of the College of Surgeons are, by the resignation of these gentlemen, placed in a position which they could not foresee at the time that they sanctioned the admission of certain ladies to this examination for the diploma of the licentiate in midwifery. They are unable to examine these three ladies, though they have admitted their names as candidates. They are unable to withdraw from their agreement, and they are unwilling to elect to the examinership in midwifery junior members of the profession.

To escape from this dilemma they are driven to appeal to the Privy Council. They go to the Government like a stale-mated king to acknowledge that they are willing to move, but on every square they fall in check.

What will be the end of all this? Last year the General Medical Council threw upon the Government the responsibility of admitting women to the medical profession, but at the same time suggested terms on which they should be admitted. Early this year the women and their coadjutors appealed to the Government to remove legal disabilities to their admission to the register, and now the Council of the College of Surgeons of England go to the Government with the statement that they have attempted to carry out the request of the General Medical Council with regard to the admission of women to the examination for licentiate in midwifery, whereby they would become registered, but they are literally unable to do so. In this way the Government are requested to decide upon what they will doubtless regard as a wrong inflicted upon a small section of the public; in fact, the Medical Council and the College of Surgeons press the Government to admit *women* to the medical profession.

THE Lord Mayor of London entertained at a banquet in the Mansion House on Saturday evening, the "representatives of literature in its various branches." The guests numbered nearly 300.

Another Death from the Abbots Ripton Accident.

We regret to have to announce the death of Mr. Richard Burdon Sanderson, the brother of an eminent member of the profession. It will be remembered that Mr. Sanderson was travelling with his wife and two daughters by the express train from Newcastle to London on the 26th of January, when the catastrophe befell it at Abbots Ripton, by which his two daughters were killed and he and Mrs. Sanderson were seriously injured. It was thought at first that he would recover, but the symptoms becoming unfavourable, he died on the 30th April. His death causes a serious loss to Newcastle, in the corporation of which town he was an active member, and a great promoter of reforms. He was also one of the county magistrates.

The Rotunda Hospital, Dublin.

The governors of this hospital have recently adopted important recommendations for the reorganisation of the extern maternity department of the hospital and the daily dispensary. They have adopted a report from the House Committee in the following terms :—

In consequence of the past increase in the number of patients seeking extern relief from the hospital—some to be attended at their homes in their confinement, and others to be prescribed for at the daily dispensary—the House Committee have had under their anxious consideration the best means of rendering this important department of the hospital as effective and complete as possible, being convinced that such will be in strict accordance with the main objects of the charity, and with the recommendations of several Parliamentary commissions appointed at different times to examine and report upon the condition of the institution. With this view they beg to recommend the appointment of a resident pupil, to be selected by competitive examination from any number of pupils nominated by the Master, who shall have creditably passed through the full course of instruction in the hospital, but shall not have obtained any registrable qualification. The examination to be conducted by the Master and his assistants, and also, if possible, by one or more of the ex-masters. The appointment of the successful candidate must require the sanction of the Board of Governors of the hospital, and the resident pupil shall enter upon his duties subject to the following rules and conditions :—

1st. The appointment to be held for six months only.

2nd. The resident pupil is prohibited attending any medical or surgical hospital, or any anatomical courses of lectures, during his term of residence.

3rd. He is to be supplied with coal and gas, and to have a furnished bedroom in the hospital, and be paid a stipend at the rate of £30 a year.

4th. He shall have no authority or responsibility with regard to the treatment of patients in the hospital.

5th. He shall be subject to suspension by the Master for neglect of duty or improper conduct of any kind, such suspension to be reported to the Board at its next meeting, when it shall be decided whether he is to be dismissed or reinstated.

6th. The duties devolving on the resident pupil shall be as follows :—

a. To record carefully and regularly in the registry book provided for the purpose all the extern lying-in cases, and all the extern chronic cases treated at the daily dispensary.

b. To attend all the extern labour cases, or see that they are duly attended by the pupils on duty, and in cases of danger or difficulty to call in the aid of the Master, or one of his assistants.

c. To make a daily visit for the week succeeding delivery to each of the patients confined at home ; to see that they get the medicine ordered ; and to acquaint the Master or assistants of any serious deviation from natural convalescence.

d. To report to the Master or assistants negligence or misconduct on the part of any pupil of the hospital of such a nature as to reflect upon the character of the institution.

e. To keep an accurate record of the cases treated in the chronic wards in the case book provided for that purpose.

Since the accession of the present Master, Dr. Atthill, to office, the governors have displayed great activity towards the improvement of the hospital, and have decided on the immediate carrying out of much needed improvements. A separate building for the extern department, with pupils' sleeping rooms, is to be erected, and extensive repairs effected.

Medical Men in Merchant Ships.

We are bound to accept the statement of the Government, given by Sir Charles Adderley in the House of Commons on Friday last. In reply to Captain Pim, "that Clause 230 of the Merchant Shipping Act, 17th and 18th Vic., c. 104, providing that every foreign-going ship having 100 persons or upwards on board should carry a qualified medical man, was by no means a dead letter." Last October the Board of Trade issued a circular to inquire whether the act was carried out in this respect, and in the answers to it only four cases of neglect, which had occurred at Liverpool, were mentioned. From inquiries since made at 18 of the principal ports in the kingdom they found that the act was very strictly enforced." Perhaps Her Majesty's Government will allow us to express a reasonable hope that the information obtained is from reliable, not interested sources.

The Medical Sanitary Officers of Dublin and the Public Health Committee of the Dublin Corporation.

It will be within the recollection of our readers that on a recent occasion the Public Health Committee of the Dublin Corporation called together the dispensary medical officers of the City in their capacity as sanitary officers, with a view of conferring with the committee upon the causes of the "inordinate mortality" of the city. The medical officers unanimously declared that the cause of the high death-rate of the City was the unsanitary state of the City and the dwellings of the working classes, and recommended certain remedies for these conditions. These opinions and recommendations of the medical officers were suppressed, and on a question being put to the Chief Secretary for Ireland by Dr. O'Leary, Sir M. Beach gave an answer already published, which was shown to be founded on incorrect information. Dr. O Leary again repeated his question on the 1st of this month, and was informed by the Chief Secretary that "the meeting broke up, but five of those who were engaged in it remained, and proceeded in an informal manner to discuss the question submitted to them, and other questions in addition, and they arrived at similar resolutions similar to those quoted. That report has not been published because the resolutions were arrived at informally." This statement differs materially

from that prevlously made by the Chief Secretary, and is not in any way more satisfactory. The statement a month ago was that certain statements were made by the sanitary officers' meeting, and when in this month it is found out that those statements are not made, Dr. O'Leary is informed that the resolutions referred to by him were arrived at, but "having been arrived at informally," they were not published. The last statement of the Chief Secretary amounts to this, that no formal conclusions were arrived at, and that the informal ones could not be published.

We have very good reasons for knowing that the conclusions stated by Dr. O'Leary to have been arrived at by the meeting on the 15th of March were perfectly formal, passed in a formal manner, received formally, and, we, believe, entered on the minutes of the proceedings of the Public Health Committee. Further, we know that evidence to this effect can be produced before any legally constituted tribunal charged with investigating the case. It is right here to state that Sir M. Beach is in no way to blame in this matter. He distinctly stated that he derived his information from the Local Government Board of Ireland. The question now to be answered is—Who supplied the incorrect information to the Local Government Board? So long as this question remains unanswered neither the profession nor the public will rest satisfied.

Hanging on Scientific Principles.

Although the principles enunciated by the Rev. Professor Haughton, in a communication to our columns some months ago, have been carried into effect in several executions since then, the opportunity has not occurred, up to the present time, to test by dissection the accuracy of the learned Professor's calculations in reference to the cause of death in hanging, and the best means of producing the fatal lesion. In an execution which has recently taken place at Hamilton, in Canada, the subject has been followed out by careful investigation, and the truth of Professor Haughton's anticipations conclusively established.

The prisoner, named M'Connell, was executed for a very atrocious murder of his landlord at noon-day, by repeated stabs of a butcher's knife. Professor Haughton's paper had been copied from our columns into those of the Canadian papers, and thus attracted the attention of the jail officials, who carried out all his suggestions *literatim*. He was very slightly made, and weighed only 138 lbs., so that apprehension was felt that it would not be easy to effect instantaneous death. The drop given was 10 feet, and the knot was placed, as in Montgomery's case, under the chin, so that the strain of the fall might take effect as nearly as possible at a right angle to the vertebræ. The death was apparently quite instantaneous, and a post-mortem examination—as sworn to by Dr. Roseburgh, surgeon to the jail—showed the following appearances;—"There was extravasation of blood under the integument, and rupture of the sterno-mastoid muscle on the left side. The second vertebra was fractured through the right superior articulating process, near its posterior border, and the left lamina was fractured posterior to the left superior articulating process; both fractures extended into the vertebral foramana; there was some displacement between the second and third vertebræ; the heart was examined, and the right side was found full of dark fluid blood, the left side empty and contracted; the brain was subsequently examined, and nothing abnormal found excepting some congestion. The immediate cause of death was the fracture of the spinal column of the neck at the second vertebra.

Illness of Prince Koffee.

The young Prince Koffee, of Ashantee, who is being educated at the Surrey County School, has been suffering from illness. The symptoms were at one time so alarming that the Government, who were apprised of the fact, sent Dr. Quain to see the Prince and report upon his condition. The health of the Royal African patient has now considerably improved.

Another Centenarian.

On Saturday afternoon Charles Young, a Peninsular veteran, who has died at the age of 108, was interred in Echo Bank Cemetery, Edinburgh. He was born at Coldstream in 1769. He entered the Scots Fusilier Guards, and was in the engagement at Corunna, Talavera, Barrosa, Salamanca, and Vittoria. At Barrosa he was wounded. The deceased leaves a large number of descendants, and his eldest daughter, who is still alive, is 80 years of age. He died in Edinburgh on Friday week.

The Royal Hospital for Incurables.

The twentieth anniversary dinner of this institution, graced by the presence of many ladies, has just been held at the London Tavern, Bishopsgate Street, under the presidency of Mr. Philip Twells, M.P., who was supported by the Sheriffs of London and Middlesex in their robes of office. While proposing the toast "Success to the Royal Hospital for Incurables" the Chairman pointed out that originally the pension granted by the board was £12 12s. yearly, with in some cases medical attendance. Of this class of pensioners only 25 remained at the date of the report, and it was proposed to allow them for the future £20 annually without medical attendance. Notwithstanding the loss of special donations through the deaths of benefactors, the financial statement of the past year must be regarded as satisfactory. The number of inmates at present at West Hill, Putney, was much greater than at any former period. The pension list increased in a still larger proportion, the amount distributed last year being £6,836. At the close of the speeches the Secretary announced the list of subscriptions as amounting to over £1600.

Kirkcaldy Epidemic.

The epidemic at the colliery village of Kingseat is rapidly gaining ground, nearly ninety cases being now under treatment. Attendance on the fever-striken population is taxing heavily the medical gentlemen of the district. One sample of the water, which is brought from Loch Fittie, has been analysed and found good in quality and the cause of the epidemic is still undiscovered.

Ventilation of the Royal Academy.

THE almost insufferable inconvenience experienced by visitors to the Royal Academy from a want of purer air and a better system of ventilation called forth a rebuke from the Duke of Cambridge at the annual dinner on Saturday week. We trust this matter will not be lost sight of, as every one will heartily echo the wish of the Duke that something like "a happy medium were established" between the cooler and more agreeable outer air and the insupportable and depressing stuffiness of the interior. The utter sense of exhaustion produced by breathing for one single hour the close, used-up air of the galleries has of late become, if possible, more detrimental and disagreeable by the enterprising spirit with which the governing body of the Academy "do furnish forth an empyreumatic odour of funereal bak'd meats," largely mixed with the deadly carbonic acid of the ever-flowing crowds of human beings.

Election of Examiners, Royal College of Surgeons in Ireland.

THE Fellows of the Royal College of Surgeons in Ireland met on Tuesday the 2nd inst., being the first Tuesday in May, as defined by the charter, to elect examiners for the ensuing year. Of the eight examiners of the Surgical Council one, Dr. Robert Mac Donnell, did not seek to be re-elected, being, in all probability, an unopposed candidate for the vice-presidency, for which the election will take place on the first Monday in June. For Dr. MacDonnell's examinership five candidates offered themselves—Dr. Frazer, Dr. Gogarty, Dr. Peter Little, Dr. Swan, of Stevens's Hospital, and Dr. Robert Persse White, of the Meath Hospital. According to the prescribed method, the following seven councillors were chosen by lot to elect: Mr. Ledwich, Dr. Mapother, Dr. MacNamara, Mr. Tufnell,

These gentlemen having been sworn according to the usual form, retired to deliberate, and on re-entering the room reported to the President that they had elected Dr. Gogarty. The several Courts of Examiners for the ensuing year will be therefore as follows:—

For Letters Testimonial and Fellowship—John Barker, Henry Gray Croly, Edward S. O'Grady, William H. O'Leary, Benjamin W. Richardson, Edward A. Stoker, William Thomson, Henry J. Gogarty.

In Midwifery—Henry Croly, John R. Kirkpatrick, William Roe.

In General Education—Frank Davys, Michael J. Malone, Robert Morton.

MR. JOHN RUST, a surgeon, whilst driving at Toppersfield, near Clare, Suffolk, on Saturday, was struck by lightning. He and the horse were instantly killed.

AN outbreak of typhus fever has occurred in the mining village of Kingseat, in the West of Fife. The epidemic is assigned to impure water supply.

HER Majesty the Queen, will open in person the Exhibition of Scientific Instruments at South Kensington Museum, on Saturday week next. France, Germany, and Russia will be largely represented in the exhibition.

THE Surgical Society of Ireland has appointed Mr. Joliffe Tufnell, Dr. Rawdon MacNamara, Mr. William Stokes, and Dr. Mapother, to represent the society as delegates at the forthcoming Centennial Congress at Philadelphia.

THE Queen has been graciously pleased to confer the honour of the Companionship of the Civil Division of the Order of the Bath on Mr. John Simon, F.R.S., medical officer of the Privy Council and of the Local Government Board.

THE French Ambassador presided on Saturday last, at the annual festival of the London French Hospital and Dispensary. A list of subscriptions amounting to about £1,000, including a donation of £100 from the Queen, was announced.

IT is estimated that the proposed new hospital at Wakefield will cost £10,092. The subscriptions in hand or promised towards the purchase of the land, and the cost of the building have already reached the sum of £14,000, and the work is, it is stated, to be commenced at an early date.

DR. H. K. KING, late of Welwyn, Herts, has been presented with a handsome inkstand, bearing the following inscription:—"Presented to Henry Kirwan King, M.B., C.M., on his leaving Welwyn, by the members of the Literary and Social Club, in token of their esteem and appreciation of his services as chief founder and first president."

DR. C. C. GIBBES, who has been filling the post of house surgeon to the South Devon and East Cornwall Hospital for the past two years and a half, has been presented with a very handsome dining-room clock, bearing the following inscription:—"Presented to C. C. Gibbes, Esq., M.D., by the students, matron, nurses, and servants of the South Devon and East Cornwall Hospital, as a token of esteem, on his leaving Plymouth."

THE works connected with the conveyance of pure spring water from the Scarrough Mountains to the town of Cahir, originated through the generosity of Lady Margaret Charteris, have already commenced under the superintendence of an eminent engineer connected with the London waterworks. The gift will be a priceless blessing to the people of Cahir, who, owing to the great scarcity of pure water, had generally to use, at great risk, river water for domestic and other purposes.

Correspondence.

RICHMOND WATER SUPPLY.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—We regret that when inserting our letter to you of the 14th April, denying in express terms the statement contained in your paper of the 5th, that the Southwark and Vauxhall Company had supplied unfiltered water to Richmond, and that the Vice-Chancellor Malins had used the expression therein quoted, you should have thought it right, instead of frankly admitting the errors, to have repeated the

principal charge in another form, and sought to justify your misstatements with respect to the Vice-Chancellor's judgment by saying that you did not confine yourselves to the "exact words of the Vice-Chancellor."

If this is meant to imply that the Vice-Chancellor used language to the same effect, it is also untrue, as the Vice-Chancellor's judgment contained nothing whatever to the purport of that which you cited as having been said by him.

The statement as to the Southwark and Vauxhall Company having "for a considerable period used a double set of pipes, one of which supplied the town with unfiltered water," is declared by the Company's engineer to be totally untrue.

We request that this denial may be inserted in your next issue.

Yours obediently,
BIRCHAM and Co.,
Solicitors to the Company.

60 Threadneedle Street, 2nd May, 1876.

[We readily give insertion to the letter of the Messrs. Bircham, who write to us on behalf of the Southwark and Vauxhall Water Company. We maintain, however, that we were ustified in our remarks from the evidence given before the Government Commissioner at Richmond. It was distinctly stated that at one time two sets of pipes supplied water to the town; we are nevertheless quite ready to accept the statement of the Company's engineer that it has no foundation in act. At the same time we would direct Messrs. Bircham's particular attention to "*The Memorial*" presented by the vestry and inhabitants of Richmond to the Local Government Board, March 14th, 1874, in which they will find it stated "that from 1835 to 1861 Richmond was supplied with water drawn from the Thames opposite the town, and within the tidal influence, and delivered to the consumers without *subsidence or filtration.*" This appears to be very like proof positive of our statement that at one time the town of Richmond was supplied with unfiltered water. Further, we learn from the memorial, that for twelve months at least after the transfer of the Richmond Water Company to the Southwark and Vauxhall (that is, from 1860 to about 1862 or 1863) water was supplied to the town without any change in the mode of supply, and we naturally infer, "without subsidence or filtration." It is also distinctly stated in the memorial that "the water is taken by the Southwark and Vauxhall Company from the Thames at Hampton; but *it is the fact that the Company can, whenever they feel it to be convenient so to do,* supply the town of Richmond with water direct from Hampton in the state in which it *is thus obtained from the river.*" We are aware that this allegation was denied by the counsel who appeared for the Company; but, on the other hand, one engineer of some eminence attested to its truth. Professor Frankland's analysis of the Southwark and Vauxhall water made on the 7th Nov., 1874, appended to the memorial, also goes far, in our opinion, to substantiate this statement, for he says: "I find the water slightly turbid, and on this account alone not fit for dietetic purposes without previous filtration. It contains a large proportion *of organic matter, some of which is of animal origin,* and it also exhibits a considerable amount of previous sewage or animal contamination. It is hard, and therefore unsuitable for washing. It is not a desirable water for the supply of a town, and is in respect of all its most important qualities greatly inferior to the sample of water from the artesian well at Richmond recently analysed by me." The *Surrey Comet,* commenting upon the evidence given before the Commissioner, says: "Some of the most eminent scientific men of the day have given it as their opinion that the water was decidedly objectionable, and contained when taken from the mains and cisterns *living organisms of an objectionable kind;* and while some of their statements were disputed, the impartiality of Dr. Frankland's evidence, was freely admitted by the Council." Furthermore, several credible witnesses agreed that the water was most unwholesome, In the *Surrey Comet,* June 5, 1875, we read that "Mr. Jones produced a bottle of water containing five small fishes, which had been sent to him by Sir Henry Parker with the message that the fish were delivered to him through the pipes of the Southwark and Vauxhall Company, and that a large number had been delivered in the same way." If we turn to the monthly report of the Government Water Examiner for March, 1876, we find that the specimens examined by Professor Frankland of the water supplied by the Southwark and Vauxhall Water Company contained "blue cotton fibres and numerous living organisms." Will this not be accepted by Messrs. Bircham as satisfactory and conclusive evidence of the truth of what we have stated?—ED. M. P. & C.]

A SMALL CONTRIBUTION TO THE STATISTICS OF VENEREAL DISEASE IN LONDON AND PARIS.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Having had occasion to visit recently the Hôpital du Midi of Paris, I was afforded the opportunity by my friend, Dr. Charles Mauriac, physician to that hospital, of examining the out-patients applying for relief on Friday, March 4, 1876. M. Mauriac supplied me with the diagnosis of each case, and allowed me to examine each patient carefully myself, so that I can vouch for the accuracy of the following statistics:—Fifty-six out-patients presented themselves at the "consultation" that morning, of whom forty-three were venereal cases. These venereal cases were thus constituted: Twenty-seven cases of gonorrhœa, two cases of soft sore, seven cases of hard sore, and seven cases of secondary syphilis. The men affected with gonorrhœa had contracted their disease, according to their own account, from non-registered women in twenty cases, and from registered women in seven cases. The men who had soft sores had gained them, one from a registered prostitute, the other from a non-registered woman. The men with hard sores had obtained them from non-registered women in six cases, and from a registered woman in one case.

I was much struck with two or three points in this small statistical attempt. Firstly, it was most remarkable to note how very few cases of soft sore there were met with—only two, whilst there were seven hard sores. Dr. Mauriac has written a pamphlet quite recently, this year 1876, on that point, and has asserted that occasionally soft sore is not seen at the Midi for weeks together. But what was remarkable also was the great paucity of cases of venereal disease at the famous male venereal hospital of Paris, which is resorted to by venereal patients from every quarter of that immense city.

My friend, Mr. Hayman, house-surgeon to the Metropolitan Free Hospital, had at my request made a similar inquiry as to the nature of the venereal cases (males) at that hospital on the 21st February last. Now, although that hospital is not a venereal hospital in any special sense, Mr. Hayman found that of the surgical cases attending on 21st February, 1876, which amounted to ninety-six cases, there were no less than fifty-six venereal cases. These venereal cases were of the following description:—There were twenty-two of gonorrhœa, nine of soft sore, and twenty-five of *syphilis,* by which is indicated two of hard sore, thirteen of secondary eruptions, and ten of tertiary affections. Thus there were in one morning more venereal cases in a small hospital in London (fifty-six to forty-three) than in the famous male venereal hospital of Paris.

I have before mentioned in a criticism of Dr. Mauriac's pamphlet "on the rarity of the soft sore at this moment in Paris," that true syphilis is increasing in amount in Paris just at the time when the soft sore is becoming rarer. It would seem that in London the soft sore is still far commoner than the hard (five to two), if we may judge by Mr. Hayman's figures of February 21st. It seems to me that a good deal might be effected if we had some more frequent comparison of statistics between London and Paris on this point. Gonorrhœa and syphilis, as I said, seem to be more common than formerly in Paris, whilst the less important, because local, venereal affections are greatly decreasing in amount.

I remain, Sir, your obedient servant,
CHARLES R. DRYSDALE, M.D.

17 Woburn Place, Russell Square,
London, April 26, 1876.

CERTIFYING OF DANGEROUS LUNATICS IN IRELAND.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Having been called upon by the constabulary to examine a dangerous lunatic, who is a comfortable farmer, having done so, and attended before two magistrates at petty sessions, to certify as to his state, I applied to them for an order for payment, under 38 and 39 Vict., cap. 67, sec. 14, but was told by them that I should apply to the friends of the lunatic. Were they justified in so doing? as I consider that under the Act (which does not mention rich or poor) I am entitled to an order upon the Board of Guardians.

I remain, Sir, faithfully yours,

RUSTICUS.

The following is the clause of the Act :—

14. Notwithstanding anything in 30 and 31 Vic., cap. 118, sec. 10, it shall be lawful for any two justices causing any person to be examined by any medical officer as therein mentioned, if they think fit so to do, to make an order under their hands and seals upon the guardians of the union to which such person belongs, for the reasonable remuneration to such medical officer, and for the payment of all other reasonable expenses in or about the examination of such person, not exceeding in the whole the sum of two pounds.

All moneys so ordered to be paid by the guardians of such union shall respectively be advanced, paid, and raised in like manner as any other moneys required for supporting and maintaining the destitute poor of such union.

It will be observed that the magistrates have a discretion whether they shall grant an order or not. They may therefore send the doctor to the patient's friends, but there is no law for their doing so.—ED. M. P. & C.

Obituary.

MICHAEL DONOVAN, M.R.I.A.

WITHIN a few days of the death of Sir William Wilde there has passed away from the Irish scientific firmament a not less brilliant light, though one whose services to science in Ireland were too little appreciated. Michael Donovan, a much respected and very earnest worker in scientific pharmacy within the last quarter of a century, has been called away from the labours which he so well loved, and leaves behind him nothing but sincere esteem for his honesty and his worth, and respect for his talents and industry. He was for many years the only pure and genuine pharmaceutist in Ireland, for, loving the science with which it was his profession to deal, he despised and avoided the aping of medical practice which the Irish Apothecaries' Company so much coveted. During all the years when practical and scientific pharmacy was neglected by those who had its guardianship in Ireland, and when it was not considered reputable by the *parvenus* of the Apothecaries' Hall to keep a shop or compound drugs, Michael Donovan devoted himself steadily to chemistry and pharmacy, and displayed an admirable contempt for the flesh pots of the medical profession after which the Irish apothecaries hankered. The Dublin *Daily Express* describes him as "a small thin man, with a face more than ordinarily marked with 'the pale cast of thought'—an eminently refined and *spirituelle* face—with a lofty brow, and silvery locks escaping from the black skull-cap he always wore, resembling more an alchemist of the middle ages than what one would suppose Michael Donovan, M.R.I.A., of this nineteenth century, would be like."

Mr. Donovan was one of those instances of which there are too many amongst our scientific men, where, from an intense eagerness of research, the mind has been led into several diverging paths of inquiry rather than concentrated upon some one special subject, by supreme devotion to which some great result might be attained.

Notwithstanding, however, the versatility of his mind, Mr. Donovan in one peculiar branch of study—electricity and galvanism—made certain discoveries that were declared by Sir Humphrey Davy to be an advancement in the knowledge then possessed on these subjects. Of this versatility notable evidence appears in the catalogue of scientific MS compiled and published by the Royal Society of London, 1868. Therein we find 27 papers contributed by him, amongst them several on such subjects as the following: "Magnetism," "Malic acid," "The nature of alcohol," "A new theory of galvanism," "The inadequacy of electrical hypotheses," "Experiments on the impurities of hydrogen," "On the oxides and salts of mercury," "On the method of smelting lead ore," "On the deflections of the magnetic needle," "On the preparation of phosphorus," "On the universal vitality of matter, and its exaltation into vegetable and animal life"—this paper, in particular, being one of remarkable power; "A description of a horizontal sun-dial." Nor do the results of Mr. Donovan's studies appear only in the proceedings of the great society on the other side of the Channel. In the list of papers read from time to time in our own Royal Irish Academy we find, amongst many, these of especial note—"Regnault's condensing hygrometer," "On Earl Stanhope's alleged imperfections of the tuning fork."

As early as 1813, Mr. Donovan obtained a premium from the Royal Irish Academy for the best essay on "The effects of the discovery of galvanism, both as regards the theory of chemistry and as an experimental agent." The substance of this essay was incorporated in a work published by Mr. Donovan in 1816, and as late as 1875 the aged student produced a remarkable paper on the comparable self-acting hygrometer. Mr. Donovan was also the author of two volumes entitled "Domestic Economy," published in Lardner's Cabinet Cyclopædia, and of the "Treatise on Chemistry," contained in the same work, which went through a second edition.

In addition to his literary efforts, he was the inventor of several pharmaceutical preparations, some of the most important being the "Arsenical Solution," "Ung. Hydrarg." "Syrup. Cinchonæ," "Ung Citrinum Fuscum."

With the ruling passion strong in death, the ceaselessly active mind of this untiring thinker, cased in a feeble, failing body, worked at the problems in which it had ever delighted, to within a few days of the supreme change—a quiet, unpretending, but most useful and learned life came to its end in ripeness of years, and another name was added to that obituary of distinguished Irishmen of which we may well be proud.

Literature.

A BIENNIAL RETROSPECT OF MEDICINE, SURGERY, AND THEIR ALLIED SCIENCES, FOR 1873-74. (*a*)

THE subscribers to the New Sydenham Society are to be congratulated on the publication of another of these excellent retrospects.

We have not failed to look over the eight reports composing this volume, and consider that their compilers have been very careful in their references and quotations, which are so numerous as to render it highly instructive and useful.

The most fastidious student of medicine will find in its paragraphs, although generally and necessarily short, a large amount of information regarding the progress of physiology, practical medicine, surgery, ophthalmology, midwifery, and the diseases of women and children,

(*a*) "A Biennial Retrospect of Medicine, Surgery, and their Allied Sciences, for 1873-74." Edited by Mr. H. Power, Dr. Shepherd, Mr. Waren Tay, Mr. R. B. Carter, Dr. C. H. Carter, and Dr. T. Stevenson, for the New Sydenham Society. London: 1875.

medical jurisprudence, materia medica, and therapeutics, and on questions connected with public health.

In corroboration of this remark, we may mention that Mr. Power's report on physiology and the allied sciences contains about 287 references to and quotations from, recent writings on these subjects; Dr. Shepherd's report on practical medicine not fewer than 2,255 references and quotations; Mr. Waren Tay's report on surgery, 575 references and quotations; Mr. Robert Brudenell Carter's report on ophthalmology, 49 references and quotations, and includes an excellent *résumé* of a valuable report by Mr. Nettleship on the ophthalmia which occurred in certain pauper schools; Dr. Charles Henry Carter's report on midwifery and the diseases of women and children, 253 references and quotations. In this report there is evidence of slight carelessness on the part of its author, who tells us that "Dr. Rota also reports (*Gaz. Med. Italiana Lombardie*, Oct., 1873) a case of Cæsarean section performed on a woman who died in the ninth month of her fourth pregnancy of anasarca."

We have not before heard of a "pregnancy of anasarca"!

Dr. Thomas Stevenson's report on medical jurisprudence contains 72 references and quotations. Of these the one from the return received at the *Mining Record* office reveals some startling facts in connection with the manufacture and sale of arsenic. It appears that in the year 1873 there were produced in England 5,449 tons of arsenic, of which more than a third came from the Devon Great Consols Mine. Now the Rivers Pollution Commissioners report that the drainage from the works from this mine contains "no less indeed than 0·42 grains per gallon of water, their suggested standard permitting only 0·035 part: but this drainage is not discharged directly into the Tamar, but is first mixed with a very large volume of water used in the mine for power only." At this single mine so much as 165 tons to 200 tons of white arsenic are sold in a month. The Commissioners regard it as a startling reflection that there leaves this mine, even at the lower rate of sale, white arsenic sufficient to destroy the lives of more than 500 millions of human beings.

There is some obscurity in Dr. Stevenson's quotation from the Commissioners' report. It states that the "Commissioners saw stored in the warehouses of the mine, ready packed for sale, a quantity of white arsenic probably sufficient to destroy every living animal on the face of the earth. They add that it is perhaps still more startling to reflect that there is at present no efficient law to prevent many fold this amount of this deadly material from being cast every month into the rivers and watercourses of this country." We fail to see what is meant here. Is it that the amount in the above warehouses reaches rivers and watercourses generally, or a many fold amount reaches all the watercourses from this mine?

We find, in this report also, a quotation confirmatory of Dr. Russell's (the *Times*) graphic description of the postures in which were found many of the corpses on some of the Crimean battle-fields. It states that "Rossbach relates a number of cases observed on the battle-fields of Beaumont and Sedan where the corpses had become rigid in the exact position they had assumed just before death, even when such position was opposed to the action of gravitation." "The expression of the countenance, the position of the hands, &c., were all as retained in rigid sculpture." "The cadaveric rigidity must have come on between the last moment of life and the first moment of death, and not later, otherwise the muscles must have become relaxed, or the position of the limbs altered by the action of gravity."

We are glad to have the opportunity of referring to this question, having heard Dr. Russell's account of the positions in which some corpses were found on the Crimean battle-fields, attributed to the impulse of an eloquent but imaginative pen.

Finally, Dr. Thomas Stevenson's report on materia medica and therapeutics, and his report on public health, contain forty abridged descriptions of new remedies and new views on the actions of old ones, as well as thirty-five references and quotations on matters connected with public health.

In the latter report there is a quotation from some instructive observations of M. Pvey on the influence of violet light upon growth. M. Pvey, it is stated, "details striking facts relative to the favourable influence exercised upon the growth of animals and vegetables by violet light. It having been observed that the growth of vines was greatly promoted and the crop of grapes largely increased by growing the plants beneath violet glass, animals (pigs and calves) were reared beneath similarly coloured glass; and comparative trials were made with coloured and uncoloured glass. It was found that the animals kept beneath the violet glass increased much more rapidly in size and weight than those beneath uncoloured glass." We have not heard of violet glass having been tested for these effects in this country, which, if not exaggerated, may lead to great advances in our floriculture, and in the rearing of the lower animals, and possibly of man himself.

Further on in this report there is the description of the important investigations of Dr. P. R. Lewis on the degree of heat essential for the destruction of vitality in the cysticercus, a question of vast moment to pork-consuming people. "Dr. Lewis, who experimented upon both beef and pork, states as the result of his investigation—(1) That exposure to a temperature of 120° Fahr. for five minutes will not destroy life in cysticerci, but that they may continue to manifest indications of life for at least two or three days after such exposure. (2) That exposure to a temperature of 125° Fahr. for five minutes does not kill them; but (3) after being subjected to a temperature of 130° Fahr. for five minutes they may be considered to have perished. After exposure to this and higher temperatures, in no instance 'was he able to satisfy himself' that the slightest movements took place in their substance when examined, even under a high power. At least it may be confidently asserted that, after exposure for five minutes to a temperature of 135° to 140° Fahr., life in these parasites may be considered as absolutely extinct. It thus appears from the careful and concurrent experiments of both Pellizzari and Lewis that cysticerci of all kinds, whether found in beef, veal, or pork, cannot retain their vitality when exposed to a temperature of 140° Fahr."

The report gives us some interesting information on the frequency of tape-worms in Florence. Pellizzari, to the question asked by Marchi, "how it happened that, notwithstanding the occurrence of 13,000 measled pigs in the public butcheries of Florence, he had seen but one specimen of *T. solium*, whilst thirty-four could not have originated in the pig?" replies, "that it is because the hygienic regulations of the city require that the flesh of the pigs be raised to 140° Fahr.;" and he then himself immediately proceeds to ask another question, namely, as to how it happens that the *Tænia solium* is so frequently seen in other places? He remarks that there are not so many sanitary precautions taken in other places, and that the people elsewhere consume more slightly salted or uncooked meat, as sausages and so forth. He explains "that Marchi's thirty-four tape-worms might all have arisen from the consumption of the cysticercus of the ox," and then goes on to speak of the presence of tape-worm in Florence, even in little children. This last-named feature he attributes to the circumstance that raw meat is frequently employed as a restorative. He remarks that thirty years ago it was just as difficult to find a single *T. mediocanellata* as it is now easy to find a great number of these worms; and all because it is now-a-days customary to eat the flesh of the ox either insufficiently cooked or raw. Pellizzari thinks that this absolute inversion of the facts of the case affords proof of the correctness of the position sustained by him that the cooking of meat up to the degree of temperature ne-

cessary for ebullition ensures the destruction of the cysticerci. These observations should be a warning to those who are in the habit of prescribing raw meat for invalids.

Many years ago the writer of this notice, at the period when minced raw meat was so strongly recommended in the treatment of chronic diarrhœa in children, was led to prescribe it for a child labouring under this affection. To his horror, some weeks afterwards he had to treat the child for tape-worm, which there is every probability had its origin in the raw-meat treatment of the diarrhœa.

Before concluding we feel compelled to remark that this volume, as regards binding, is a great improvement on its predecessor, which was so badly stitched as barely to keep together.

The usefulness of the volume is much enhanced by the index, which is both copious and accurate.

DALTON'S PHYSIOLOGY. (a)

Professor Dalton's work has long held so high a position in this country, as well as in America, that the appearance of a new edition will be generally welcomed, for great changes have taken place since the appearance of the last. The excellencies of this work have been so appreciated by some that we have known lecturers in our London medical schools confess that they only "preached Dalton," though this is perhaps more to the author's credit than to that of the lecturers in question. It shows, however, a very high estimate of the American professor's work. There are special points about it which commend it to a large class of readers. In the first place it is not a mere compilation, but rather a well-digested course of physiology. As such it is the exponent of the author's own views, and he is peculiarly free from crotchets. We may therefore regard his work as a thorough and complete digest of the present state of physiological science. Partly in consequence of this, the references are not numerous in comparison with those which are found in works partaking more of the character of compilations. By many this will be deemed an advantage, and students especially may be glad to be relieved from the distraction attending the statement of conflicting views. The frequent changes of opinion or substitutions of theory presented as physiological discoveries, however interesting in themselves, are of little value to the student, though carefully observed facts, even when they may be thought peculiar, possess permanent value. The author has not lost sight of this, and therefore he informs the student not only of the results now in our possession, seen of course from his own point of view, but gives an account of the means of investigation by which these results have been attained. One of the greatest advantages of this method of teaching is that it enables the learner to distinguish between what may fairly be considered positive and what is at present only hypothetical, so that the announcement of a new discovery does not confuse him, even though it may lead to a change of opinion.

In the chapter on Digestion we have been particularly pleased with the description of the gastric follicles, and certainly those who are unable to gather from this a definite idea of the nature and use of these bodies in the several parts of the membrane cannot be complimented on their facility of apprehending facts. There are other points which are more lengthily dwelt upon, but we select this because it has the additional merit of great brevity. But we will pass over the first section of the book, which is devoted to nutrition, to mention the second, which treats of the nervous system. In this department of physiology so many important advances have been made that we turned to it with great interest. Difficult as the subject confessedly is, we have here a compendium of it which any careful student may easily understand, and we may certainly say that within the same compass it will not be easy to find so clear and accurate an account of nervous physiology. Recent investigations into the localisation of the functions of the brain are succinctly described and their general results impartially stated. The investigations of Fritsch and Hitzig are accepted as important contributions to science, as are also the more recent labours of Braun and Putnam, and the Committee of the New York Society of Neurology, the report of which was issued last year. The confirmation of these researches by English observers is not alluded to, and this reminds us that the work throughout gives that prominence to American investigation which we should naturally look for in a text-book of American origin, and intended primarily for American use. We find no mention of Brown-Sequard's objections to the views of Fritsch and Hitzig, though possibly this is because the work was partly printed before his last utterance. We should have expected, however, to find on so new a subject a statement of the objections that have been raised by French critics and experimenters, some of which seem to be of the highest significance.

It is perhaps, however, to the third section of the volume, which is devoted to the reproductive system, that we should refer as Professor Dalton's masterpiece. We believe this to be the clearest description of the physiology of the reproductive system in our language, and we especially commend the first chapter, in which bacteria and their relation to spontaneous generation are passed in review. Some of our physiologists would do well to read this chapter, and endeavour to express themselves with the same clearness, conciseness, and moderation.

With regard to the special changes in this edition, we may state that the new chemical notation and nomenclature are used throughout, the centigrade system is also adopted for measurements of length, volume, and weight. Temperatures are given in degrees of the centigrade scale, but usually accompanied by the corresponding degree of Fahrenheit scale enclosed in brackets. The additions and alterations necessitated a large increase in the matter of the work, estimated by the author to be fully equal to fifty per cent. Nevertheless, by careful typographical arrangement, the volume is by no means too bulky. The illustrations now reach 316 in number. The majority are good, but a considerable number are merely diagrammatic, and the execution of a few is scarcely worthy of the excellent type and paper. In conclusion, we may state our belief that this edition of his work is worthy of the author's high reputation.

(a) "A Treatise on Human Physiology," designed for the Use of Students and Practitioners of Medicine. By John C. Dalton, M.D., Professor of Physiology and Hygiene in the College of Physicians and Surgeons, New York. Sixth edition. Revised and enlarged, with 316 Illustrations. London: J. and A. Churchill. 1876.

CLINICAL LECTURES ON DISEASES OF THE URINARY ORGANS. (a)

In this work are found the subjects of the course of clinical lectures which the author is in the habit of giving yearly in the wards of University College Hospital. Each edition contains modifications and improvements, for Sir Henry Thompson is not only a progressive surgeon, but is anxious to make his hearers and readers as able and as successful as himself. The book is written in an extremely forcible and agreeable style. The sentences, though short and conversational, are well-considered. In fact, the busy practitioner and the young student can equally profit by and enjoy the perusal, while the hospital surgeon will do well to look into it to find an example of what clinical teaching should be. If we have to find fault with the book, we shall point to the back of the cover, on which we find inscribed, "Diseases of the Urinary Organs;" the inscription should have been "Clinical Lectures." As a treatise on diseases of those organs it is manifestly imperfect; as a course of clinical

(a) "Clinical Lectures on Diseases of the Urinary Organs." By Sir Henry Thompson. Fourth Edition. London: J. and A. Churchill. 1876.

lectures it leaves nothing to be desired. If the author had intended the title to catch the eye of unprofessional readers the existing one would doubtless have been well chosen.

Sir Henry Thompson does well to insist upon the necessity for students studying the nature and microscopic appearances of healthy and morbid urine; and in the last chapter gives most excellent advice upon the manner in which they should conduct their examination. The last chapter is a most valuable addition, for in it are found a short chemical account of the various salts found in different specimens of urine, and methods for distinguishing blood, pus, and mucus, as well as other bodies accidentally introduced. In addition to this are appended six small circular drawings of objects which are liable to be found in any specimen of morbid urine. Whilst speaking of the deposit found in a fluid which has been left at rest, the author says (p. 374):—"Lastly, agitate an equal quantity of liquor potassæ with a portion of the deposit, and if the latter be pus a dense gelatinous mass will result, while if it be merely mucus it will be less dense than before." We are told that we must be particularly careful to obtain a proper specimen or specimens of urine for examination. If, for instance, a patient be suffering from an urethral discharge, and bring us some of the first part of the urine voided, we shall find albumen in the fluid from the liquor puris, and may possibly be misled. We should be provided with two specimens; the first will contain the "flushings" of the urethra, the last the unmixed contents of the bladder.

Sir Henry Thompson admits but one variety of stricture, organic. "And this organic stricture," he continues, "is a permanent condition" (p. 31). Later on he tells us a great deal about the treatment of organic stricture by cutting, dilatation, and rupture, but he tells us at the outset that when a man once has organic stricture he has it for ever. Of course it may be remedied, but it can never be absolutely cured. Concerning "inflammatory stricture" and "spasmodic stricture," he says the former is really due to severe prostatitis, and that the patient no more has a *stricture* than has he who is unable to swallow on account of enlargement of the tonsils a stricture of the œsophagus. "So with regard to what is called spasm . . . . The affection is only temporary; it does not necessarily imply any organic change, and is not stricture of the canal." "I will tell you," says the practical teacher to his pupils, "what spasmodic stricture often is: it is an exceedingly useful excuse for the failure of instruments."

On page 72 are found instructions for passing a catheter, which are as minute as they are valuable. When a small silver catheter is to be employed, an injection of a few drachms of olive oil into the urethra is advised. But Sir Henry Thompson cautions his hearers about the danger of solid instruments, and of small ones in particular. "No one," says he, "has been a greater advocate than I was some years ago of solid instruments as against soft ones." But now he has "no hesitation in saying that a great part of the success of any man who has much to do with this subject will depend upon his use of flexible instruments as against solid." He justifies his change of opinions; and further on he tells his pupils that they "may rely upon it, with regard to any subject whatever, whether politics or religion, or our own proper profession, if we hold the same opinion at forty years of age as we did at twenty—and perhaps, looking forward, I may say, if we hold the same opinions at sixty as we do at forty—we live to very little purpose." Such a paragraph naturally caused us to pause a moment and think.

In cases of inflammatory retention, where the patient is in great distress (p. 126), we should not adopt "the classical treatment of thirty years ago," giving opium in large doses so as to enable the patient to bear the pain and dispense with the catheter. We should pass a small flexible catheter (No. 6), well curved, so that it may ride up over the enlarged prostate, but we must introduce it with great care. We are well able to speak of the success of this treatment, but we have no doubt it will be a long while before a student will dare to express the opinion in an examination.

THE SURGEON-OCULIST TO THE QUEEN IN IRELAND.

ALTHOUGH it has been known that the succession to this distinction is regarded with much interest in Ireland, the MEDICAL PRESS AND CIRCULAR has, for reasons which will be readily understood, abstained from advocating the special claim of any surgeon to favourable consideration. If similar reticence had been observed by the other journals, we should have preferred to maintain silence, but as the qualifications of one competitor for the distinction have been put forward, and opinions strongly expressed in his favour in the pages of one Irish daily paper, and one professional contemporary, it will not be expected that the MEDICAL PRESS AND CIRCULAR shall permit those opinions to pass as unchallenged and incapable of dispute, or shall continue to withhold from any candidate that publicity for his qualifications which has been afforded to another through the medium of the press.

Dr. Jacob is senior in the practice of his speciality in Ireland, having for fifteen years, both before and after his entrance into the profession, acted as the pupil, and as the surgical assistant, to his father, Dr. Arthur Jacob, in which capacity experience and tulelage were afforded to him which no ophthalmic surgeon in Ireland enjoyed. He possesses the qualification of an academic education, having obtained with honours the degrees of Master in Arts and Doctor of Medicine in the University of Dublin, and has given guarantees of his professional competency as a practitioner and an operator in his capacity of Ophthalmic Surgeon to the City of Dublin Hospital and the Dublin Eye and Ear Infirmary, and has manifested his interest in the investigation of eye diseases by numerous contributions to the literature of the subject in these columns. Finally, he may fairly claim to have deserved and to enjoy as large a share of the confidence of the public and of the profession as any other ophthalmic surgeon in Ireland. It is not for us to say more.

As a public man Dr. Jacob has been foremost in the politics of his profession, and—we believe it may be truthfully said—has been considered to have always acted independently and honestly according to his views of the interest of the profession. On the retirement of his father from the administration of the Royal College of Surgeons, in which he had acted thrice as President and for a quarter of a century as Councillor, Dr. Jacob was elected by the Fellows of the College almost without a contest. For a long series of years—in spite of occasional differences of opinion as to the accuracy of his medico-political views—the Fellows have repeated their vote of confidence, and Dr. Jacob still holds post of honour in the profession as a Councillor of the College.

In simple justice to Dr. Jacob's claims to consideration, which have been disregarded in other quarters, the MEDICAL PRESS AND CIRCULAR states these facts, submitting those claims to the unbiased judgment of the profession and of her Majesty's advisers, who will no doubt

recommend for her Majesty's selection the surgeon possessing the highest qualifications, not only strictly professional, but also those academic.

ELECTION OF A PROFESSOR OF ANATOMY IN THE IRISH COLLEGE OF SURGEONS.

At a meeting held on the 27th inst., to elect a Professor of Practical Anatomy in room of the late Dr. John Morgan, Mr. William Thornley Stoker, of 16, Harcourt Street, Dublin, Fellow of the Royal College of Surgeons in Ireland, Surgeon to the Richmond Hospital, and formerly Surgeon to the City of Dublin Hospital, was duly elected.

The candidates who presented themselves for the chair were Dr. Loftie Stoney, Ophthalmic Surgeon to the City of Dublin Hospital, and a Demonstrator in the College School; Mr. Corley, Lecturer on Surgery in the Carmichael School, and Surgeon to the Richmond Hospital; Mr. Foy, Lecturer on Anatomy in the same school; and Dr. Charles Robinson, a Demonstrator in the Ledwich School.

On the seven Councillors being selected by lot in the usual way a circumstance occurred which gave rise to same discussion, and which we observe is referred to in a very inaccurate and injudicious way in the columns of a contemporary. Amongst those Councillors who were drawn to elect was Dr. Jacob, who had not arrived at the time when his name was called out, but entered the room a few moments afterwards. Meanwhile another name had been called, and the question arose whether Dr. Jacob was bound to serve or whether, on the other hand, having been absent at the call, he should be allowed to decline and the name drawn subsequently substituted for his. The clause of the Charter which rules this point is as follows:—"The President together with not less than two-thirds of the other members of the said Council for the time being in that behalf convened shall assemble, and being so assembled, shall choose and appoint by lot seven members of such Council or as near thereto as may be, which said persons so chosen and appointed shall proceed forthwith to elect by a majority of voices such Professor, provided the said members of Council so by lot appointed shall find among the candidates for the said office a person having such qualifications as the Council may from time to time determine by bye-law to be necessary, and also being in the judgment of a majority of them fit and competent to discharge the duties." It will be observed that this clause does not provide for the absence of any Councillor, but orders seven to be "chosen and appointed by lot" from those who have assembled. This requirement the President ruled to have been complied with when the Councillor elected entered the room at any time previous to their swearing in, and Dr. Jacob was therefore directed to serve as an elector.

After deliberation the electors declared their choice as above, and the selection will be approved by the profession.

THE ALEXANDER MEMORIAL FUND.

The Committee of the Alexander Memorial Fund have offered a Prize of £50 and a Gold Medal of the value of £10 for the best essay "On the Influence of Drinking-water in Originating or Propagating Enteric Fever, Diarrhœa, Dysentery, and Cholera; to be illustrated as far as possible by instances which have come under the personal observation of the author." Essays to be forwarded to the Committee on or before the 31st of December. The competition to be limited to executive Medical Officers of the Army on full-pay. The relative merits of the essays will be determined by assessors chosen by the Committee.

The election of a surgeon to Swift's Hospital for Lunatics in Dublin, in place of Mr. John Hamilton, took place last week. It will be recollected that three successive elections lately failed in consequence of an even division of votes between Mr. Colles and Dr. Thornley Stoker. The last election resulted in the choice of Dr. Stoker, who has within the same week been appointed Professor of Anatomy in the Royal College of Surgeons *vice* Dr. Morgan.

City of London Hospital for Diseases of the Chest.—The twenty-eighth anniversary festival of this hospital was held last week, under the presidency of Mr. John Coope Davis. The chairman, after the loyal and patriotic toasts had been responded to, and in advocating the toast of the evening, dwelt upon the special attributes of this hospital, and mentioned the salient facts that the institution could not be maintained at its present state of efficiency under £9,000 a year, and that the annual subscriptions reached a sum of about £2,100 to meet this drain upon the resources. In response to the chairman's appeal, a subscription list of £2,580 was announced.

Society for the Relief of Widows and Orphans of Medical Men.—The annual general meeting of the Society was held at 53 Berners Street, on Friday, April 28th, Dr. Quain in the chair. From the statement read by the Secretary it appeared that the income available for the payment of grants and expenses for the year 1875 had been £3,213 5s., showing an increase of £147 10s. on that of 1874; the expenditure had been £2939 2s., a decrease of £135, chiefly owing to the small number of applicants for fresh grants during the year; the total amount of grants had been £2,711 10s., including a donation of £253 distributed at Chrstmas among the widows and orphans. The expenses had been £227 12s. Fifty-eight widows and seventeen children had been assisted. Twenty-eight new members had been elected; twelve had died, including three Vice-Presidents and one Director, viz., Vice-Presidents, Dr. Latham, Sir Charles Locock, Bart., and Mr. Iliff, and Mr. Sercombe, a Director; eight members had resigned, or ceased to be members. The Society now consists of 404 members, an increase of 8. Two widows had been added to the list of annuitants, four had died, and five children had become ineligible. The funded property had been increased by the purchase of £1,541 6s. 2d. Metropolitan Three and a-Half per Cent. Consolidated Stock. Legacies of the value of £1,440 had been received. Mr. C. J. F. Lord was elected a Vice-President, and the following gentlemen, Directors: Mr. Birkett, Dr. Carr, Mr. Steet, Dr. James E. Pollock, Dr. Wilks, and Mr. Savory. A vote of thanks to the editors of the medical journals was carried unanimously, and the proceedings terminated by a vote of thanks to the chair man.

NOTICES TO CORRESPONDENTS.

☞ Correspondents requiring a reply in this column are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

A Poor Medical Student.—We have much pleasure in acknowledging the receipt of 3 guineas from Dr. Rees Powell, of Cwmpadest, Wales, in aid of "The Poor Medical Student," on whose behalf we inserted an appeal in a recent number of the Journal.

Caution to London Practitioners.—Two correspondents write to our contemporary, *The Lancet*, calling attention to a dodge now carried on by a well-dressed female, of about middle age, for the purpose of larceny. In each case she called, requesting immediate attendance upon a lady just arrived from Cheshire. The addresses given were different in each instance, and, of course, fictitious. Besides the annoyance of having been fooled, when they returned to their houses they found themselves minus several articles which but an hour previously were in their possession.

Dog Poisoning.—During the last two or three weeks a large number of valuable dogs have been poisoned in the western suburbs of London, and, notwithstanding the tempting rewards offered, amounting in all to between £500 and £800, and the vigilance of the police, no clue has been obtained to the perpetrators of the offences. In one case, at least, the poison employed is believed to have been strychnine. At the residence of Mrs. Coulson Campbourn, Richmond, a meeting was held a few days since and a committee formed, consisting of both ladies and gentlemen, in connection with the Royal Society for the Prevention of Cruelty to Animals, to which Lieutenant-Colonel Burdett has consented to act as honorary secretary and treasurer. An officer of the society is about to be located in the neighbourhood.

The serious illness of Dr. Kirk is reported in the last letter received by the *Western Morning News* from Zanzibar.

Royal College of Surgeons.—At a meeting of the Court of Examiners, held on the 21st April and following days, the under-named gentlemen, whose names are in alphabetical order, passed their final examination for the letters testimonial, and having made and subscribed the declaration, in accordance with the Supplemental Charter, were admitted Licentiates of the College, viz.:—Howard Blyth, James Henry Brennan, Michael Callan, Charles Ulick Carruthres, George Robert Deighton Charleton, Ebraim M'Dowell Cosgrave, Henry Royse Cunmings, Richard Henry D'Olier Duckworth, John Joseph Falvey, Robert Cardwell Gunning, William Bourne Hallows, Thomas Kinlay Hamilton, Francis Josiah Hart, George Edward Irwine, Stanislaus Maguire, Robert Nesbitt, Edward Hyacinth O'Leary, Peter O'Reilly, Thomas Pierse, Joseph Michael Redmond, Walter Ryan, George Searancke, Henry Gregg Sherlock, and Edmund Aloysius Wall, Esq.

Dr. Hawtrey Benson has been appointed Medical Referee for Dublin to the Alliance British and Foreign Life Assurance Co., in the room of the late Dr. John Hamilton.

To the Editor of the Medical Press and Circular.

5 Henrietta Street, Cavendish Square, W.,
May 3rd, 1876.

Sir,—Allow me to correct an error which appears in your journal of this date, in which it is stated that "at the levée held on Friday last by H.R.H. the Duke of Edinburgh, on behalf of her Majesty, Mr. W. Adams, F.R.C.S., the newly-elected President of the Medical Society of London, was presented by Major Cadman." I beg to state that I was not presented at the last levée by Major Cadman, but six or seven years ago, by the late Sir Henry Lytton Bulwer, afterwards Lord Dalling.

Your obedient servant,
Wm. Adams.
President of the Medical Society of London.

[We are happy to give space to Mr. Adams's correction; at the same time we would state that we copied the name from the official list of presentations supplied to the London daily papers in the usual manner. —Ed. M. P. & C.]

Clinical Society of London.—On Friday evening, at 8½ p.m. Mr. Maunder, "On three Cases of Subcutaneous Osteotomy of the Femur" (the Patients will be exhibited).—Dr. Duffin, "On a Case of Tumour of the Corpora Quadrigemina."—The President (for Mr. Leggatt), "On a Case of Intestinal Concretion passed per Anum."—Dr. Pearson Irvine, "On a Case of Diphtheritic Paralysis simulating extensive Lung Disease."

Communications, Enclosures, &c., have been received from—Dr. Rees Powell, Cwmpadest. Dr. Farr, London. Mr. Squire, London. Dr. Tamain-Despailles, Contrexville. The Director-General of the Army Medical Department. Dr. Myrtle, Harrogate. Mr. W. Adams, President of the Medical Society of London. Dr. Roberts, London. Dr. Wise, Norwood. Mr. Francis Vacher, Birkenhead. Dr. Dickinson, London. Dr. Dolan, Halifax. Mr. R. Hanslip Sers, Epperstone. Dr. Abrath, Sunderland. Dr. Carpenter, University of London. Rev. J. Alton Hatchard, St. Leonard's. Dr. Julius Althaus, London. Mr. Gray, Newcastle. Mr. Bircham, London. Mr. Porter, Dublin. Dr. McKeogh, Kilmacthomas. Dr. Carpenter, Croydon. Dr. Luther, Cappoquin. The Secretary of the Society for the Relief of Widows of Medical Men. Dr. Macauley, London. Colonel Puckle, London. Mr. Henry Sewill, London. Dr. Kirby, London. Dr. Cameron, Dublin. Mr. Bray, St. Leonard's. Dr. Langley, London. Dr. Edwards, Evansville. Dr. Short, New York, &c., &c.

VACANCIES.

Cancer Hospital, Brompton.—Surgeon. Also an Assistant-Surgeon to out patients. Honorarium. 100 guineas and 50 guineas respectively. (See Advt.)

Larne Union, Glenarm Dispensary District.—Medical Officer. Salary, £100, with £15 extra as Sanitary Officer. Address the Hon. Sec. (See Advt.)

Wolverhampton General Hospital.—House-Surgeon. Salary, £100, with board, &c. Also an Assistant House Surgeon. Board and lodgings, but no salary. Applications to the Chairman of the Medical Committee.

Stockport Infirmary.—Assistant House-Surgeon. Salary, £60, with board. Applications to the Honorary Secretary.

Ashton-under-Lyne Infirmary.—House-Surgeon. Salary, £80, with board. Testimonials to Mr. Hugh Mason, Ashton-under-Lyne.

Royal Infirmary, Liverpool.—Medical Superintendent of the Lunatic Asylum. Salary, £2 0, with £60 for wife, as matron, with board and residence. Applications to E. Gibbon, Esq., at the Infirmary.

Dursley Union.—Medical Officer. Salary, £30, with fees extra. Apply to the Clerk to the Guardians.

Keighley Union.—Medical Officer of Health for Sanitary Inspection. Salary, £50 per annum. Applications, endorsed "Medical Officer of Health," to be sent to the Town Clerk's Office, Keighley.

Marriages.

Banner—Hunt.—On the 4th inst., at St. Luke's, South Kensington, Samuel Banner, M.R.C.S., of 11 Delamere Street, W., to Charlotte Augusta, only daughter of the late Major Hunt, of the 2nd Queen's.

Established 1848.

PROFESSIONAL AGENCY AND MEDICAL TRANSFER OFFICE,

50 LINCOLN'S INN FIELDS, W.C.

J. BAXTER LANGLEY, LL.D., M.R.C.S., F.L.S.

&c. (King's Coll.), and Author of VIA MEDICA.

Has always upon his books a large number of desirable Investments and available Appointments for negociation.

The business of the Professional Agency is based upon the general principle, that no charge is made unless work has been done and services rendered.

No Commission charged to Purchasers.

Full information as to terms, &c., sent free on application.

Office hours, from 11 till 4; Saturdays excepted.

COMPETENT ASSISTANTS provided without expense to principals. No Gentlemen recommended whose antecedents have not been inquired into.

LOCUM TENENS.—Dr. Langley has now organised a thoroughly reliable Staff of suitable Gentleman to take full Charge of any Practice which may require it in the absence of the principal, at fees from £2 12s. 6d. upwards, according to age, experience, qualifications, &c. One of these gentlemen can be despatched by an early train after receipt of telegram or letter stating duties and terms. Office fee 10s. 6d., payable by the principal.

PRACTICES AND PARTNERSHIPS NOW OPEN for Negociation (in addition to those advertised in Dr. Langley's List, which is sent post free on application).

A 103. PARTNERSHIP, with Succession on easy terms. Receipts average £800 a year. Appointments, about £100. The co-operation of an active gentleman would immediately increase the income. The Practice is situate in a large and prospesous town of the Midland Counties, and is easily worked. The junior Partner could reside in the house where the Practice is now carried on, this is well situate, with croquet-lawn, stabling, &c. The premium could be paid by instalments, except a sum of £300 on entry.

A 102. In a watering place on the South Coast, a very desirable NUCLEUS of Practice realising £200 a year, including an Appointment producing £100. There is a very good house suitable for the reception of resident patients. Rent, £65. Furniture at valuation, if desired. Premium, £100.

A 101. Within easy access of London, a GOOD FAMILY PRACTICE, realising £600 a year. Appointments, £200. District, agricultural. Excellent house. Rent, £45.

A 106. COUNTRY PRACTICE held by Vendor 40 years. Receipts, average £500 a year. Appointments, £130. No opposition. Nine-roomed house, with garden, stabling, and land, at a low rent. Premium, £400, part of which may be paid by instalments.

A 99. LONDON, N. In a leading thoroughfare of an improving district, an Old-established Practice. Gross average receipts, £430, capable of great increase. Midwifery, £1 1s. and £2 2s., under 50 cases a year. Patients middle-class. Convenient house in a first-rate situation, on beneficial lease. No assistant, horse, or carriage necessary. As the Vendor is going abroad, he is prepared to concede easy terms to an immediate applicant, who can be efficiently introduced.

A 98. First-class Practice in a provincial town, within 40 miles of London. Receipts, £1,200 a year, and steadily increasing. Midwifery, 2 guineas and upwards. Introduction by way of partnership if desired. Good professional residence, fitted with modern conveniences, with coachhouse, stabling, &c. Part of the premium may be paid by instalments.

A 97. Within 80 miles of London, a Sound Country Practice, realising £800 a year in actual receipts. Appointments, upwards of £220. Working expenses small. Introduction as may be desired, and every guarantee of good faith given. The house is small, but very convenient, and well situate. Rent, £25. Premium, 1 year's purchase, half of which may be paid by instalments.

ON THE RIGHT OF THE STATE TO OBTAIN EARLY INFORMATION OF THE APPEARANCE OF EPIDEMIC OR INFECTIOUS DISEASE IN A GIVEN DISTRICT—OUGHT THE MEDICAL ATTENDANT TO BE THE INFORMER? (a)

By Alfred Carpenter, M.D. Lond., M.B., &c.

The right of the State to obtain the earliest possible information as to the prevalence of epidemic or infectious disease in a given district can scarcely be doubted for a single moment, yet at the present time there is no law by which that information can be gained until fatal cases have occurred, and the registrar of deaths gives the note of warning in his report to his superior officer.

Whilst more than 100,000 persons are annually sacrificed in this country to the neglect of proper sanitary precautions, a consideration of the point raised in the Health Department, at the Brighton Congress, will not be out of place.

A resolution was passed at that meeting—"That it be recommended to the Council to take into consideration the desirability of compelling, by legislative enactment, medical men attending cases of an infectious character to report the same to the medical officer of health." Hence the following observations.

The right of the State to the information is not questioned; it cannot be reasonably urged that there is no case for the exercise of such right in the face of the fearful mischief entailed by preventable disease, and what is required is the appointment by law of a regular informant at its first onset.

When we consider that into a district, comparatively healthy and thickly peopled, a man, recovering from small-pox or typhus, may locate himself. In a short time the house he occupies, the sewer he uses, or the privy he frequents, becomes a focus from whence the malady may spread to all who are prone to take on the disease in question who may be exposed to its influence.

The State has a right to limit this mischief, and to do that to an individual establishment which it does not hesitate to do, to a whole community under similar conditions, when they arise in connection with intercourse between nations—viz., to establish a proper quarantine whilst the mischief is in a nutshell, whilst it may be limited to a single house in a given district. There is at present no power enabling the recognised officer, whose duty it is to control the ravages of epidemic disease, to get at the truth and find out the strength of his hidden enemy, and to do for the house that which we do not hesitate to do for a nation.

If the medical officer of health hears that a form of disease, in which he is specially interested, has made its appearance in a particular house or place, and in consequence makes a personal effort to obtain reliable information, he is told by the occupier that the Englishman's house is his castle, and that he has no business there. Should he succeed in gaining admission, and have an interview with the patient, examining into his condition and diagnosing the disease, without making any communication with the ordinary medical attendant, he is liable to be brought to the bar of public opinion in the medical press, and pointed out as a wrong-doer, as forgetful of that etiquette which is so essential in the intercourse of professional men one with another. In the interests of a whole neighbourhood, it does seem urgently required that there should be some legislative enactment to remedy this defect, and to assist in limiting the spread of infectious disorders, without the medical officer of health being liable to rebuff and insult in the performance of his duty.

The Act of 1866 is the first step which was made by Parliament to control the personal liberty of the subject in the matter of infection. The 38th clause of that Sanitary Act imposed penalties upon persons who exposed themselves and endangered others whilst suffering under the effects of infectious disease. The 39th clause imposed a penalty upon those who let houses in which infected

(a) Read before the Social Science Association.

persons had been residing before they had been cleansed. The State, therefore, in 1866, laid down the law that personal liberty should be restricted in such cases, but it made no provision for the compulsory discovery of the disease itself. The fact, as to the commencement or the particular position of a given case, is still liable to be concealed, and the enactments contained in the Act of 1866, which is now a part of the Public Health Act, 1874, makes the discovery of the whereabouts of disease much more difficult than it was, because some persons find their liberty impeded, their comfort interfered with, and their pecuniary interests seriously involved, if even the rumour of the existence of such disease arises in connection with their establishments.

Rumour does them as much harm as the fact itself—hence hotel-keepers, shopkeepers, lodging-house keepers, and even private families, find it to their apparent interest to keep the fact of the presence of infection in their houses a secret from their most intimate friends. It follows, therefore, as a matter of course, that the enactments already passed, admirable though they are, do almost as much evil as good, and will continue to spread mischief, unless an additional clause can be passed into law, by which it should become the duty of some recognised person to give immeidate information of the onset of special diseases to the local authority, whose duty it is to take public measures for its arrest.

The Legislature of New Zealand have passed a law requiring every medical man who becomes cognisant of the presence of such disease in a given household, to give such information to the local authority; and the question immediately arises as to whether we should not follow the example which has thus been set us by one of our youngest colonies.

Ought not a legislative enactment to be passed to compel medical men attending cases of infectious disease to immediately report the same to the medical officer of health of the district? How is the medical officer of health in a given district to get the information he so urgently requires as to the presence of infection at a given spot if not from the medical attendant, who is probably the first to diagnose the disease, and who ought to immediately suggest the proper remedies for its localisation? the first of which is to inform the local sanitary authority.

The reports of medical officers of health in all parts of the country teem with evidence of the desirability of such information being afforded to them at an early date; many of them make the suggestion that medical officers of health should be able to demand the information as a right from the medical attendant on the case. The subject has, however, to be considered in other lights than that with which the medical officer of health views it; and before deciding upon the propriety of a legislative enactment being pasfed, to make it compulsory upon a private medical attendant to give the information required, it will be prudent for us to look at its effects from some other points of view.

1. Would the medical officer of health get all the information he requires if such a law was made? Would he have at command all the information he desires, and always be on the trail of the disease immediately it made its appearance? This question must be answered in the negative, because great numbers of infectious cases of disease are not even now placed under the care of recognised medical men. Of these cases, therefore, the medical officer of health would get no information; and if the parents or guardians, or the persons affected, were anxious to keep the matter secret, they would not consult a qualified and regiltered practitioner, but place the case in the hands of some unregistered or unqualified person, who would not be amenable to the law. Thus the danger to a given neighbourhood would be increased, whilst the chances of recovery to the patient would be lessened. This result would be certain to happen with some lodging-house-keepers, hotel-keepers and shopkeepers. The principals of most of such places of resort are generally anxious to avoid publicity, and keep the presence of disease in their establishments a secret from those visiting them, and would strongly object to its being known to the local authority.

2. A legislative enactment which applied only to medical men in such cases, would act very injuriously against the interests of sanitary perfection. The repression of disease would only act in the same direction as at present, viz., by making it still more difficult to get at the truth, and harder still to keep a district free from the chance of disease spreading in it by unsuspected channels.

3. Such a piece of legislation would also be against the interests of the medical profession, by giving a bonus to unqualified practitioners, and would, therefore, be pecuniarily objectionable to the medical profession.

4. But a still greater objection is to be found in the fact that it would to some extent alter the feeling of mutual trust and confidence which ought to exist between the doctor and the patient. If a medical man, in the practice of his profession, becomes aware that his patient has broken the laws of his country, and that fact has been made known unto him by accident in the treatment of the case, and for the purpose of enabling the medical attendant to treat it more correctly, there is no obligation upon that medical man to become a common informer, and to give information to the police which might lead to the apprehsnsion of the culprit. If, however, the medical man in attendance is placed in the witness-box and is examined as to his knowledge of certain matters which may tell against his client, he is not privileged to withhold them from the court, but he is not called upon to volunteer any information upon such points which may criminate his patient unless instructed by the judge that he must answer any questions and give all the information which is in his power upon the point at issue.

(To be continued.)

AN ESTIMATION OF THE FREE AND ALBUMINOID AMMONIA YIELDED BY THE STAGNANT WATERS OF THE DUBLIN STREETS, AS COMPARED WITH THE QUANTITIES OF THOSE SUBSTANCES OBTAINED FROM THE LIFFEY WATER AFTER RECEIVING THE SEWAGE. (a)

By Lancelot Studdert, LL.D., Ex-S. T.C.D.

During the Session of 1874-5 of the Royal College of Science, Stephen's-green, several examinations were made there of Dublin well-waters; and also some determinations like those that follow for the river water. As a sequel to those analyses, the suggestion of the Professor of Chemistry in that college, Mr. Galloway, induced me to undertake a series of estimations of the ammonia yielded by the surface-water of some streets and squares in Dublin, taking as the standard of comparison the water of the Liffey near where the sewage is discharged into the river.

The results of my examination, conducted during November and December last, in the College of Science Laboratory, are now laid before the Royal Irish Academy.

Altogether twenty-nine of these street waters were examined; the samples dealt with were collected, in my presence, at the times and places stated in the Table appended to this paper; the mud, also, left from some of these pools, was examined for ammonia, which reached two parts in the hundred, calculated after allowing for moisture expelled at 212 deg. Fahrenheit. The river water was collected at intervals during the two months, from four different places, namely, at Eden-quay, Aston's-quay, Burgh-quay, and Sir John Rogerson's-quay, four hours after high water at Dublin bar.

The method employed for determining the quantity of ammonia yielded by these waters and muds is that devised

(a) Read before the Royal Irish Academy, 10th January, 1876.

by Messrs. Wanklyn and Chapman. This process is almost universally allowed to be the best yet made known for ascertaining the character of the nitrogenous matter in waters; its quantitative results are accurate, and they are obtained with rapidity. It may be well to state, for the information of any unacquainted with the Wanklyn and Chapman process, that under the term "*free ammonia*," those chemists include ammonia not only present *as such*, or in combination with acids, but also the ammonia that, after adding a saturated soda carbonate solution, is evolved by distillation from urea, or other easily decomposable nitrogenous organic bodies. The term *free ammonia* is therefore not strictly correct; but, taking it in this special sense, it would be difficult to substitute any other term more convenient, or less open to objection.

The Table of results gives the figures for the Liffey standard at the head of the list. The quantities of the free and the albuminoid ammonia obtained from the several street and Liffey waters are calculated as grains in the gallon, and also as milligrammes in the litre of each water, respectively, examined.

The average of free ammonia from the four samples of the river is 0·0982, or under one-tenth of a grain in the gallon; the average of albuminoid ammonia from the same is 0·0779, or under one-twelfth of a grain in the gallon.

It may be interesting to note that the examination of the river water referred to as having been made by other workers in the College of Science Laboratory in 1874, gave a result equal to my average in 1875; thus showing a remarkable constancy in the state of the Liffey.

It may also be remarked in passing that my average for free ammonia is less, but for albuminoid ammonia is greater, than the average Messrs. Wanklyn and Chapman reported as that of the Thames at London-bridge, in June, 1867; that river, the tide being at two hours flood, yielding free ammonia=0·1232 of a grain per gallon; and albuminoid ammonia=0·0245 of a grain to the gallon.

The average of free ammonia obtained from the 29 street waters is 17 grains to the gallon; that is, over 170 times the like average from the river. The average of albuminoid ammonia from the street water is 3 grains to the gallon, or 38 times the Liffey average.

It will be seen by the Table, that from three out of the four river samples, the quantity of free ammonia was under that yielded by any of the street waters, except at Stephen's-green, East and South.

The maximum of free ammonia from the river was at Burgh-quay, and only reached 0·175, or less than one-fifth of a grain to the gallon; whilst the maximum of free ammonia from the street waters, namely, at Moss-street and Poolbeg-street, was 10·5 grains to the gallon, that is exactly 600 times greater than the river maximum.

The *least* impure of the 29 street waters yielded nearly three times more albuminoid ammonia than the *most* impure sample of the river water; for instance, the surface-water at Merrion-square, South, being the best of the street waters, yielded 0·280 of a grain, against that obtained from the river at its worst, namely, 0·098 of a grain, or nearly 3 to 1.

But the bad pre-eminence of the water in Moss-street and at Peter-place (corner in Adelaide-road) and in Lee's-lane, off Aston's-quay, namely, 10 and 10·15 and 11·2 grains of albuminoid ammonia from one gallon of each water, respectively, is more than 100 times greater than the Liffey maximum.

Messrs. Wanklyn and Chapman conclude from a wide induction of experiments that "the disintegrating *animal refuse* in the river [Thames] would be pretty fairly measured by *ten times* the albuminoid ammonia which it yields." In this way, the average of such refuse in the Liffey is 0·779, or just three-quarters of a grain in the gallon; whilst the average of such refuse in the street waters is 29 grains to the gallon.

That much of this enormous amount of animal matter thus in our midst must, if not rapidly removed, take forms that will vaporise, seems all but certain, since the conditions for spontaneous decomposition may be said to be always present: there are the moisture and heat required for this chemical change, and then there occurs at intervals the drying up of these stagnant pools.

My examination of these street waters found, as might be expected, sulphuretted hydrogen, with other sulphides and very offensive volatile substances.

What the effect must be on the people's health who dwell in an atmosphere contaminated by exhalations such as these, it is not for me to determine; this paper simply records the facts of the case, leaving conclusions to those physicians who make such researches their peculiar study. But without knowing the least of the little that is known, even to the medical faculty, about either the chemical or the germ-theory as to the propagation of disease, yet one of the unlearned, like myself, having but ordinary sagacity might correctly conclude that the continued presence of so much dirt in the streets would go far to account for the high death-rate (33 to the 1000 yearly) lately recorded for Dublin; a city whose situation, other things being equal, might mark it out as one of the healthiest in the Empire. The London *Times* last week, reviewing "Ireland at the close of 1875," laid this to our charge—that "dirt reigns, and slays its thousands in Dublin and elsewhere."

Whatever is to be done with our street sewage, whether it is still to defile the natural purity of the river, or to be applied to improve the land, or only to be thrown away, with great cost into the sea; whatever be the destination of this noxious mass, whether it is to be good, bad, or indifferent, it certainly appears, from the results now laid before the Academy, that better scavenging and a level surface for the streets is at once required.

The Professor of Hygiene and Public Health in University College, London (Dr. Corfield), in reference to this subject, in the "Manual of Public Health," edited by Hart, states that:—"If the streets, roads, and ways of a town or district are allowed to become or to remain so out of repair as to become receptacles for filth, or to afford, by their inequalities, depressions in which foul water accumulates, it is in vain to look for beneficial results from other sanitary measures."

THE PATHOLOGY AND RELATIONS OF ALBUMINURIA. (*a*)

By W. Howship Dickinson, M.D., F.R.C.P.,

Physician to, and Lecturer on Pathology at, St. George's Hospital; Senior Physician to the Hospital for Sick Children.

LECTURE II.

The lecture commenced with a consideration of the secondary lesions which ensue upon the cardio-vascular change proper to the granular kidney. The retinal change, involving hyperæmia, serous infiltration, hæmorrhage, and white spots, was described as due to arterial leakage or rupture connected with vascular deterioration and increased pressure. The optic state, generally spoken of comprehensively as albuminuric retinitis, was not peculiar to the granular kidney, though most commonly associated with it. It was found sometimes both with diffuse nephritis and lardaceous filtration.

The retinal was to be regarded as but the outward and visible sign of a universal vascular change. It almost always showed advanced renal disease; though with the granular kidney it might occur while as yet the disorder had been undeclared by any other prominent disturbance, and thus constitute its first obvious symptom. The form of renal disease most apt to become thus complicated was that which sometimes ensued upon pregnancy—a fact to be, perhaps, explained by the increase of vascular tension which normally belongs to this state. The exceptions to the general rule which associates the granular kidney with albuminuric retinitis, though not numerous, were sufficient

(*a*) Abstract of the Croonian Lectures.

to show that there was no necessary pathological connection or identity of kind between the renal and the retinal change, but only that the retinal change was the expression of a condition which, though most common with the granular kidney, was not peculiar to it.

The association of the same form of renal disease with other hæmorrhagic lesions, more particularly with cerebral apoplexy, was considered. It was shown that two-thirds of the instances of fatal extravasation within the skull were of renal origin; and the occasional occurrence of cerebral hæmorrhage even in childhood, when the kidneys were granular, was exemplified by a striking instance in a girl of twelve.

Passing to the inflammatory results of the disease, pericarditis was insisted on as especially connected with it. As a pathological rarity, a peculiar form of ulceration of the small bowel had been found in connection with, and apparently due to, the renal change. The ulcers were described as affecting the lower end of the small bowel, and as setting up local peritonitis.

Two instances of renal granulation as affecting children were given in detail, and others briefly referred to, showing that at the earliest periods of life at which the disease was found the cardio-vascular changes were present, the heart and arteries being constantly thickened, while cerebral and retinal hæmorrhages were of occasional occurrence.

Touching upon the association of the renal change, as part of a common fibrosis, with a similar change in other organs, it was shown that, taking the liver as the test, renal and hepatic fibrosis so seldom occurred together that they must be generally looked upon as due to separate causes, not to any general fibrotic tendency. And with regard to general fibroid thickening as the result of age, it was inferred from the examination of three nonagenarians to be less frequent than fatty, calcareous, and atrophic changes. The conclusion was generally stated that, putting aside for the present the associated affections of the arteries, the kidneys became the subjects of fibrotic change for the most part alone, as the result of a morbid instigation proper to themselves, not distributed over many organs.

Proceeding to inquire into the causes of the organic change, it was shown that in most cases they could not be isolated, but belonged to the common ways and even tenour of life. Hereditary influence could be sometimes discovered, as was illustrated by reference to an ancient family in which three generations, comprising seventeen individuals, had furnished eleven subjects of the disease. Climate, which to be most injurious must be temperate but variable, was a fruitful source of the complaint. Coming to causes which fall more partially, those involving mechanical congestion of the kidney, obstructive disease of the heart, and pregnancy, were discussed. The disease could be traced also to circumstances, like gout, of which the mode of action was less obvious; to the influence of renal irritants, such as lead and alcohol; it could be recognised as a late result of scarlatina, or of diffused nephritis, however induced; it occasionally appeared to ensue upon the congestion of tropical intermittents; and, finally, it was attributed to the prolonged influence of accumulated urine.

Thus showing that the renal fibrosis, though often of obscure origin, was sometimes to be traced to causes acting locally on the gland by way of mechanical congestion or specific irritation, it was next made apparent, that whether the renal disease was of determinate or doubtful source, the cardio-vascular change was equally present.

With these facts a vexed question was approached—the significance of the cardio-vascular changes, whether directly consequent upon the glandular embarrassment or only associated with it as a parallel effect of a common cause.

The albuminuric change of vessel was shown to be present not only with the fibrotic kidney of advanced life, but as constantly with that of childhood—where, to say the least, changes allied to those of age were improbable,—with the condition as traceable to mechanical congestion or modes of glandular irritation, and not less so when it ensued as the sequel of scarlatinal nephritis or nephrit s arising from cold or other mischance. The evidence already adduced that a similar arterial change may be produced by comparatively recent nephritis was reverted to, and allusion made to the observation of the same vascular state as the result of disablement of the kidney by stone or other accident.

The conclusion was held to be inevitable that the arterial and cardiac changes were not, in general, parts of a deterioration originating systemically, but were definite consequences of the glandular injury.

The nature of the arterial and cardiac changes involving muscular hypertrophy and fibroid induration, together with their occurrence in inflammatory and fibrotic disease where arterial tension is increased, and their absence with the lardaceous, with which, as a rule, whether in consequence of wasting discharges or of the little impairment which until late falls upon the secreting power of the kidney, arterial tension is little or not at all exalted, led to the belief that the structural alteration was the result of the tension by which it is accustomed and preceded.

To seek the cause of the tension or fulness of the arterial system it must be placed in obstruction of its outflow, and the only question which remained for discussion was whether the hindrance should be placed with Bright, in the capillaries, or, with Johnson in the arterioles.

Largely as Johnson's observations of muscular hypertrophy had been borne out by what had already been advanced, his explanation, according to which the heart and arteries become hypertrophied by antagonistic action, was held to be less tenable than the older hypothesis. Accepting as the starting-point of the vascular changes a condition of blood which rendered it difficult of capillary transmission, the complicated series of changes admitted of easy explanation. The heart and the arteries were together hypertrophied in their efforts to close upon the blood accumulating in them from the obstacle in front of both. With this the increased pressure on the vessel-walls caused increased soakage into them, and ultimately fibroid induration of their coats, after the manner of congestion wherever it may occur. The associated degenerative changes were probably due to the irritative effect of the impure blood. Thus, as of old, the whole pathological series was traced to glandular inefficiency and uræmic contamination.

Whether the cardio-vascular change have other modes of origin—whether, as is probable, the state of blood necessary to cause it may be produced by circumstances apart from renal disease, are questions as yet unanswered. No doubt in many cases hypertrophy of the heart gives evidence of arterial change while as yet there is little direct evidence of renal disease. In such cases the renal disease was probably more often hidden than absent. The kidneys might be so far destroyed that fatal uræmic was imminent, but the urine contain no albumen, or a scarcely appreciable trace. The vascular mischief, therefore, might occur in connection with latent renal disease; how far independently of renal disease was yet *sub judice*.

LECTURE III.

The pathology of the lardaceous change was now discussed as of an infiltration beginning with the arteries, and afterwards involving other tissues, of a material the nature of which was a matter of much interest. It had long been known that the material with which lardaceous organs were infiltrated was nitrogenous, and did not differ appreciably in its ultimate composition from fibrine and albumen. The interest chiefly lay in the points of difference between the lardaceous matter and the healthy tissues; one of the most important of these was to be found in the relation of the morbid deposit to the alkalies. The presence of the lardaceous material could be at once detected by its reaction with iodine in a manner to be presently explained. If now the weakest solution of potash or soda, or a stronger one of ammonia, be brought into contact with the

infiltrated structure, its power of reacting with iodine was at once and finally abolished, and that without any destruction of the normal tissue, or even material injury to its microscopic structure. This appeared to depend on the extraordinary solubility of the morbid deposit in alkalies, a property which Dr. Marcet took advantage of to obtain the material for analysis.

Pursuing further the relation of the alkalies to the new material, it was found that infiltrated organs, taking the liver as best suited for the comparison, were deficient in alkali, especially in potash. In a series of healthy livers the total alkaline salts gave an average of 1·0, the potash of ·209, in 100 parts. In a series of lardaceous livers the total alkaline salts averaged ·739, the potash ·169, in 100 parts. While the alkaline salts were diminished under the disease, the salts of the earths were increased. These observations had since been confirmed by some made by Dr. Dupré at the request of the Pathological Society. Comparing the mineral constituents of three healthy livers with three highly lardaceous livers, he found that with the healthy liver the potash amounted on an average to ·283 per cent., with the lardaceous to ·131 per cent. The chloride of sodium was somewhat increased in the morbid tissue.

Passing now to another organ, it was shown with regard to the spleen that parallel statements might be made. The ash of this organ had been examined in nine instances; three healthy, five lardaceous, and one of rickety enlargement. With the lardaceous change the potash was lessened, as compared to the state of health, from an average of ·311 per cent. to one of ·196 per cent. The soda varied much, but had apparently suffered no loss. The earthy salts were generally increased. With the rickety enlargement, one superficially resembling the lardaceous, though profoundly different from it, diminution was found in the earthly salts only.

Reverting to the iodine reaction by which the lardaceous tissue was ordinarily distinguished, it was described as depending on the greater absorption and retention of iodine by the morbid deposit. The supposed amyloid blue had not come within the observation of the lecturer; but the interest which pertained to this reaction, while the deposit was thought to be starchy, no longer existed now that it was known to be nitrogenous. A more obvious interest attached to the remarkable manner in which some of the normal constituents of the body could be made to yield the reaction. This could be done by imparting to them acidity. Fibrine under this influence yielded so exact a counterfeit of the lardaceous reaction that he had ventured to call dealkalised fibrine artificial amyloid matter. Fibrine dissolved in dilute hydrochloric acid gave a precipitate with iodine of the characteristic colour, and the same result could be shown on the acidified fibrine as recovered by evaporation. This manifestation of the "amyloid" reaction by certain constituents of the blood on their being transferred from alkaline to acid combination, the paucity of potash in lardaceous organs, and the extreme solubility of the morbid deposit in alkalies, which would seem to prohibit its deposition from blood of normal alkalinity—all these suggest that a deficiency of the alkaline solvent, and a consequent separation from the blood of something for the solution of which the means no longer suffice, is a rude ideal of the morbid process.

The causes of the disease were next considered. Reference was made to a series of sixty-six cases, published some years ago, which had led to the inference that the disorder was especially caused by suppuration, independently of any cachectic condition, whether tubercular, cancerous, or syphilitic, with which the discharge might happen to be associated. These conclusions were tested by a tabular analysis of 83 cases fatal in St. George's Hospital since the publication of the previous observations. Of these 60 were connected with ascertained, 4 with presumed suppuration. Cancer existed in 2, tubercle in 37, while there was evidence of syphilis, historical or pathological, in 18. Suppuration was often effective in causing the disease, when of purely local or accidental origin, as in renal stone, ovarian or pelvic inflammation, accident, surgery gangrene or bed-sores. Cachexia might be at once dismissed as not necessary to the production of the lardaceous change. Tubercle and cancer were connected with it only by means of the suppuration they so often caused. Syphilis stood in a different relation to the disorder; it was alone an adequate cause of the lardaceous infiltration, however helped by the discharge due to some of its secondary and tertiary lesions. In the table the disease was attributed to syphilis without excessive suppuration in 11 instances, while evidence or record of syphilis complicated the antecedents of 7 others.

Taking the disease as due to suppuration in the abstract, the *modus operandi* was taken into question. The infective and exhaustive results of suppuration were considered, and the lardaceous change attributed to the latter. Then as to the essential loss involved in suppuration which occasioned the result, it was inferred that of all the organic constituents of the discharge, the white corpuscles were those only which could with any probability be thought to impoverish the system by their removal. The potash of the blood was chiefly contained in its corpuscles, and largely in the white, as evident from the composition of pus. It was probable, therefore, that suppuration, which essentially consisted in the escape of these corpuscles, might produce its morbid results which were characterised by want of potash by their deficiency. Whatever were the action of the leucocytes, a discharge of pus was virtually a discharge of potash, since pus, chemically speaking, differed from blood mainly in the superabundance of this essential alkali. This loss was apparently the link between suppuration and the lardaceous deposit, and partial impoverishment of the blood and deposition of what was in relative excess presented itself as a rough outline of the process.

But besides the exhaustion of discharge, it was clear that there were other modes by which the disorder could be produced. Diminished income was as bad as increased expenditure, and defective assimilation equivalent to increased waste. Under the influence of syphilis we should be prepared to find nutrition impaired in any manner: the attenuation of its subjects showed that their food was not turned to purpose; could it be that the white corpuscles were insufficiently developed and their accompanying potash insufficiently introduced?

The organic results of the disorder, in relation especially to renal disease, were then considered, with particular reference to the irritative results of the infiltration in the setting up of tubal catarrh and intertubal nucleation, fibrosis and granulation. The occasional presence of arterial and cardiac hypertrophy was regarded as the necessary result of these secondary renal disturbances, though lardaceous infiltration *per se* had little tendency to cause uræmia, and seldom any result of this nature. No doubt the exhausting discharges productive of and consequent upon the lardaceous change kept down the vascular tension and prevented its results.

I have hitherto said nothing of the treatment of the disorders the nature and relations of which have occupied our attention. It would not be suitable that I should occupy the College with the details of recognised and familiar practice. But one or two points call for mention, and I have chosen to place them together, distinguishing, when needful, what applies to one state of kidney and not to another, rather than to incur the danger of repetition by annexing to each separately any reference to the measures by which it should be met.

In treating the disorders of the vital gland in question, our measures must not be limited by the bounds of the materia medica. The circumstances of ordinary life—food, drink, and temperature—are to be considered as of the first importance, while the contents of the Pharmacopœia occupy the position of auxiliaries whose services sometimes decide the battle, and at others are dispensed with without loss. Therapeutics to be successful must have a physiological basis. To give rest as far as may be to an inflamed structure is an old and wise maxim; and it

is not less obvious, in regard to the system at large, that if a great channel of exit be obstructed, the materials which therefore tend to accumulate should be sparingly introduced. The diet with albuminuria—save with that of lardaceous origin, in which the secreting power is until late but little impaired, while an exhausting discharge may have to be obviated—should be below the custom of health in its nitrogenous components. It may abound in in milk and farinaceous matters, while fish may often take the place of flesh. The increase of albumen in the urine upon a too early resort to a meat diet is a common experience. With regard to liquids, it cannot be too strongly insisted upon that the functional strain upon the kidney is not to be measured by the quantity of water which filters through it, but by the quantity of mainly nitrogenous refuse which it has to convert and eliminate. Water, which probably transudes almost as through dead membranes, probably makes little demand upon the real secretive function. The worst kidneys indeed, those most hopelessly incapable of their special work, will often discharge most of it. And it is easy to see that its passage is salutary both in the dilution of scanty and irritating urine, and also in washing out the solid products which, under the inflammatory process, collect mischievously in the tubes. A further use is to be discerned in this general law; the solids of the urine vary with its water. With given kidneys the solid excreta wax and wane with the bulk of the urine. Any means, therefore—mere aqueous filtration as safely as any—which increases this will also increase the components of the secretion which are essential to life. With tubal nephritis, therefore, and scanty urine, an aqueous dietary, even with the addition of distilled water, or the element in some slightly sophisticated shape, will prove in every shape beneficial. In many, perhaps in most, cases of nephritis of tubal origin, these remedies of patriarchal simplicity—"spare diet, and spring water clear" are all that are needed to guide the disorder to its natural cure.

To this surest and safest of diuretics others must often be added, both to lessen dropsy and to avert the dangers of uræmia. The old rule is that in recent cases digitalis should be used; it seldom fails to increase the flow of urine, but I am not sure that it does not sometimes do so with some exasperation of the inflammatory action. The bitartrate and acetate of potash, which have a purgative as well as a diuretic effect, may probably be more safely resorted to. In chronic cases as much as can be done harmlessly by diuretics may be accomplished with scoparium, nitre, and juniper. Cantharides and the more irritating agents of this class are generally distinctly injurious.

Perhaps, next to the regulation of the diet, it is most important to secure a daily and somewhat loose action of the bowels. Purgatives lessen the vascular tension, which in both acute and chronic cases, is a measure of their danger; and while it is not advisable too largely to divert the urinary fluids by severe catharsis, increased hardness of the pulse and other more obvious aggravations of the general state seldom fail to ensue upon constipation. When cerebral uræmia is threatening, hard purging by elaterium or otherwise is essential. As an habitual laxative a drug less used than it deserves to be—sulphate of potash—given two or three times a day, in doses of from ten to twenty grains, is sometimes invaluable. It may be aided, if necessary, by Epsom salts or cream of tartar. This or these in their laxative action clear the obscured or blood-spotted retina, and remove mists from the field of vision slowly, and not always completely, but in a manner which affords a remarkable contrast to the inutility of iron in this respect, and gives testimony as to the use of alvine evacuation in lessening the arterial tension of which such lesions are the index. The chronic headache of the granular kidney is often similarly and equally relieved.

While by such means the system is enabled to dispense as far as may be, with the renal function, it must be asked whether, particularly in circumstances of recent inflammation, anything can be done directly towards the cure of the injured organs. Discarding counter-irritation as a method of punishing the skin for the errors of organs for which it is not responsible, it must be admitted that, beyond ensuring sufficient irrigation of the tubes, our chief endeavour is to provide the gland with leisure to cure itself. But it is worth mention—especially in relation to a rapidly fatal form of nephritis, in which the tubes become widely sealed up, as if filled with molten glass, by a pseudo-croupous exudation of fibrine, the urine being almost suppressed, while the little that is passed is loaded not only microscopically, but, as a bulky precipitate, with large fibrinous cylinders—that all plugging of the tubes from this cause can be prevented by the administration of alkalies. Alkaline urine is a solvent for fibrine, and with this in process of secretion the exudation retains its fluidity and whatever harm it is capable of doing by solidifying in the tubes is obviated. The experiment is easy of trial. However numerous fibrinous casts may be—and I need not say that this term comprises all that are usually passed,—they will, upon the alkalescence of the urine, quickly cease to appear, to return again with its acidity. There are cases in which such relief to the tubes must avert apressing danger, but it is disappointing to recognise, as I fear we must, that the process of renal inflammation is seldom so simple as to admit of cure by this means.

I may say a word touching the use of iron. The impoverishing effect of albuminuria, possibly from the destructive action of the retained refuse upon the blood corpuscles, produces a pallor which cannot but suggest this remedy and in recovery from attacks of renal inflammation none is more helpful. But a medicine which is effective for good is generally, and in somewhat the same measure effective for harm; and iron in chronic albuminuria, needs to be administered with more discrimination than it, perhaps, always receives. With high vascular tension, such as belongs to the granular kidney, with a hard pulse for its sign, an enlarged heart, retinal mischief, and possibly persistent headache and nausea as concomitants, iron, however seemingly indicated by the look of the patient, is generally injurious unless most guardedly anticipated and counterpoised by aperients. The perchloride, among other salts, is often of especial service in dropsy; but where the vessels are not thus relieved and the symptoms which threatens are uræmic, this drug is generally better withheld. In any condition it seldom fails to do harm if allowed to constipate—a result which may be obviated by mixing the ferruginous salt with sulphate or bitartrate of potash.

In the treatment of granulation or lingering nephritis climate should take no secomdary place. Every organ of the body, according to the teaching of ancient medicine, was subject to a separate planetary or celestial rule—a fancy which has at least this much of truth, that functional activity, and with it the liability to disease, are apportioned among the eliminating organs largely by external temperature or solar influence. In the tropics the stress falls upon the skin and liver; in the temperate zone upon the lungs and the kidneys. The comparative exemption of the kidneys from disease, save the lardaceous kind, appears, as far as our evidence goes—and the experience of our ubiquitous race makes it tolerably extensive,—to be common to the warmer latitudes; and the inference that under the same atmospheric influence chronic albuminuria, when not of lardaceous origin, would find perhaps, not organic cure, but at least systematic relief, has been amply justified by recent experience.

Not to dwell upon the treatment of cerebral uræmia, in which the uses of drastic purging and forced diaphoresis are sufficiently well known as lessening the uræmic state, while means of controlling the nervous irritability, the bromides, chloral, and chloroform, are helpful as withholding its convulsive effects, I will say a word upon the less trite topics, the prevention and possible cure of the lardaceous condition.

This condition is one in which medicinal treatment would seem to be suggested by the nature of the morbid change, and encouraged by a tendency to natural recovery

which the disease, even in an advanced stage, will sometimes exhibit. But with the curative power inherent in the human frame, not in this case, however, so often successful as might be wished, comes the ever-present vice of therapeutics, the attributing to art what belongs to nature—a possibility of error which will probably never cease to increase the confidence of the confident practitioner, and the distrust of him who, in one sense more foolish, is wise enough to doubt.

When the disease is consequent upon syphilis, iodide of potassium is of marked effect in lessening the organic enlargement and ameliorating its other effects. Sometimes, when a long-continued suppuration has come to an end, or greatly diminished, a retrogression in the resultant disease can be slowly followed, though no antidotal drugs have found place, if only the diet of the patient be liberal and his general surroundings favourable to health. The special remedy which pathology suggests, one which of late years I have used often and largely, is potash. I have found, in the first place, that under lasting suppuration potash salts can be given, not only without the depressing effects which sometimes attend their use, but to the improvement of the general health, and with the absence of lardaceous symptoms which, in the circumstances of the case, would be at least a probable contingency. Further than this, I have given the salts of potash alone or with quinine and iron where visceral swelling, diarrhœa, and albuminuria have betokened the disorder in an advanced shape. Under such treatment the liver and spleen have become measurably smaller, the urine less albuminous, the patient has gained flesh and weight, and all the symptoms have ameliorated. But chemicals put into the stomach are not brought to bear upon the tissues as if the treatment of disease were conducted in the test-tube, and the cure is at best but a slow one. It is further obscured, or possibly stimulated, by the shrinking which the swollen organs sometimes naturally undertake. The most striking instance of recovery under treatment which has come under my notice was one in which the the disease was associated with syphilis, and the treatment correspondingly modified. Great enlargement of the spleen and liver, albuminuria, diarrhœa, and emaciation gave evidence of the disorder in a degree of seemingly hopeless severity. Iodide of potassium was given, with potash and its vegetable salts. The patient was apparently cured, and on his death from an accidental cause, three years afterwards, the viscera had returned to their natural size and shape, and only such traces of the lardaceous change were discovered as to warrant the belief that he had once had more of it.

On the whole, reviewing my experience in this matter, I am bound to admit that the administration of potash by itself has proved, I will not say useless, but disappointing; less effective than pathological inference would lead us to hope.

As to the use of remedies of the restorative and tonic class—iron, quinine, and cod-liver oil—there is unequivocal evidence. If the deficiency of potash be connected, as I have ventured to surmise, with a loss or insufficient development of leucocytes, the disorder may perhaps be more appropriately met by means which promote their formation rather than by the mere introduction of material which, in the deficiency of these essential elements of nutrition, perhaps cannot be turned to vital purpose.

The measures I have commonly, and numerous experience justifies me in saying beneficially, used have been liberal diet with beef-tea, Liebig's extract, and vegetables, all of which abound in potash salts, together with liquor potassæ, phosphate of potash, iron, quinine, and sometimes cod-liver oil. The alkaline remedies have been urged with the most advantage during the persistence of suppuration.

HER MAJESTY has been graciously pleased to confer the Companionship of the Order of the Bath, Civil Division, on Mr. John Simon, Medical Officer of the Privy Council and the Local Government Board.

THE HEALTH OF THE ARMY.

THE Army Medical Report for 1874 has just been published. It states that the average strength of the troops serving in the United Kingdom during the 52 weeks ending the 25th of December, 1874, calculated from the weekly returns of sick was 86,837; the admissions into hospital in this number were 73,004; the deaths in hospital, and those which occurred out of hospital were 735; throughout the year the average number of men always in hospital was 3,351. The proportions per 1,000 of the strength represented by these numbers are of admissions, 850·7; and of constantly sick, 38·59. In addition, however, 84 deaths occurred among men detached from their regiments; the average number of men so detached is given in the Adjutant-General's returns as 6,361. The average strength of the force serving in the United Kingdom was therefore 93,198, and the total number of deaths 819, being in the rate of 8·79 per 1,000 of the strength. The rate of admissions is 81·6, and that of deaths is ·53, per 1,000 men in excess of the corresponding rates of the previous year; both are also in excess of those of the average of the five preceding years. The report states certain considerations bearing on the subject of the less favourable health of the force in 1874 than in the previous year, and remarks that the matter is complicated by the fact that causes tending in opposite directions influenced the number of admissions into hospital in 1874. The fall in the rate of admissions for venereal disease which followed the promulgation of the Royal Warrant of October, 1873, continued through 1874. The increase in the rate of admissions for all diseases together was, therefore, in spite of the operation of a cause tending to lower the rate. Until nearly the end of the first quarter of the year the weekly rates of admission were sometimes higher, sometimes lower, than those of the corresponding weeks in 1873, but the average for the period of 11 weeks was nearly the same in both cases, being 15·54 per 1,000 against 15·60. In the last week but one of the quarter, however, an increase in the rate began, and with one exception continued uninterruptedly until the end of the year. During this period the rate of admissions averaged about one-eighth higher than that of the corresponding period in 1873. The suddenness of the rise resembled that due to epidemic disease, but no important epidemic broke out then or during the year, nor does the steady maintenance of the rise during nine months show the influence of sickness in this form; it points rather to the operation of some sustained agencies, for it seems probable that more than one contributed to the result. During the year 1874 a radical change in the previous system of hospital management and medical attendance on sick soldiers was made by the substitution of station for regimental hospitals, and it is therefore necessary to estimate what effect this may have had on the amount of sickness. As the rise in the rate of admissions began in the last week in March and the new system was nowhere established before the month of May, and then only at one station, and as the system was not generally in force until the last quarter of the year (and in Ireland not until December), the report considers it clear that the change does not account for even a considerable part of the greatly increased number of admissions into hospital, though it is the case that for some time after the establishment of station hospitals a temporary increase in the number of admissions occurred at certain stations. The higher proportion of sickness and mortality among the troops serving in the United Kingdom in 1874 than in 1873 must chiefly be ascribed to the unfavourable causes affecting the health of the general population in England in 1874, as shown in a higher death-rate. From the returns of the Registrar-General it appears that in 1873 the proportion of deaths was 21·2 per 1,000 of the population, while in 1874 the proportion was 22·3, an excess in the latter year of 1·1 per 1,000; and it is a fair assumption that an increased amount of sickness accompanied the greater mortality of 1874. Among the troops in the United Kingdom the admissions were proportionately

greater in every class, and also in every separate group of diseases than in 1873, excepting in two, for the unconformity of which in one instance there is an obvious explanation; and not only were the admissions from sickness more numerous, but those caused by accidents were greatly in excess—in a smaller strength they were 1,401 more in number, and the deaths following them were 17 more than in 1873. The report observes that no doubt the rate of admissions and of deaths in the year 1874 was also somewhat raised by the circumstance that many invalids from abroad, instead of being sent to Netley, joined their depôts, and the records of their admissions and deaths were not always kept distinct from those of the other soldiers. In many instances, probably, their illnesses were returned among those of the United Kingdom, the result being that more admissions and deaths were attributed to the force serving at home than were due to illness contracted there, and also that the rates of mortality due to service at stations abroad were a little understated.

Clinical Records.

ST. MARY'S HOSPITAL.

Under the care of Mr. A. T. Norton.

Compound Comminuted Fracture of Tibia and Fibula, with Protrusion of Four Inches of the Tibia separated from the Soft Tissues, and denuded in part of Periosteum—Antiseptic Treatment—Cure.

Reported by Mr. Percy Jakins.

Patient was admitted on the 15th of November. Says that he was sent to cut off a piece of oil-cloth from a roll of it, and in trying to take the roll out of its place it slipped and fell on his leg, at the same time throwing him to the ground. The roll was about 9 cwt. in weight. When brought into the ward it was seen that he had got a severe compound fracture of right tibia and fibula, at middle and lower third, with about 4 inches of upper fragment of tibia protruding through the wound, and torn away from all the soft tissues. The wound was about six inches in length. Both arteries were felt pulsating. Mr. Norton decided that an attempt should be made to save the limb. A piece of the protruding bone was sawn off (about three-quarters of an inch), and when extension was made on the foot the bone returned to its normal position, but would not remain so until the limb was secured to a back splint. The wound was brought together by three sutures, and dressed throughout by Lister's antiseptic method, a tube being introduced into the depths of the wound.

At 11 p.m. the patient had a sleep for a few hours, and was feeling comfortable. In no pain. Tongue moist and clean. Pulse 84. Temp. 99.6.

On the following day, the 16th, he stated that he had been rather restless since one o'clock, and that he felt some pain about the wound on account of the parts being hot; an ice-bag was applied, which gave great relief. Wound redressed at 2.45. Parts looked very healthy; there was a little lymph around wound. Pulse 108. Temp. 97.8.

On the 17th he had had a good night's rest, and did not complain of any pain. Tongue moist. Bowels freely relieved. Wound redressed and looking well. There was a clot of blood occupying the wound, but no bleeding took place whilst the wound was exposed. Pulse 88. Temp. 98.4.

18th.—Patient doing very well. In no pain. Has slept well. Skin moist. Tongue clean. There was a collection of lymph on the dressings, but no pus whatever. Pulse 108. Temp. 98.4.

19th.—Felt well, and had slept well; but the appetite had not been so good. The sutures were removed, and the wound is looking remarkably healthy. Some granulations were to be seen, and the clot of blood which had formed in the wound was apparently organising. Pulse 116; temp. 100·2.

20th.—Was going on well. Wound looked healthy; but the skin around was a little inflamed, no doubt the resulting irritation of the carbolic acid. A piece of protective was applied to the wound dry, instead of being moistened with carbolic acid. Tongue clean and moist; bowels regular; pulse 100; temp. 100.

21st.—Patient had not slept, and complained that he felt great pain in his foot, which seemed to "jump" On dressing the wound it was found that the padding had slipped, and was pressing on the heel, and when this was removed the pain ceased. Pulse 108; temp. 99·4.

22nd.—Had slept well; was in no pain; appetite good; wound going on well. The granulations small, and covered with a layer of lymph. A small piece of bone of the upper fragment was bare of its periosteum. Pulse 102; temp. 98·4.

24th.—On the 9th day after admission the lymph which escaped from the depths of the wound was slightly turbid with pus. The face was a little flushed, and the tongue was coated. Pulse 92; temp. 99·4.

27th.—On dressing the wound the drainage tube came away, and could not be reintroduced, as the space was occupied by granulations; the upper part of wound had cicatrized. Pulse 100; temp. 99·6.

The wound was dressed daily, and on the 30th the notes state that there was a quantity of healthy pus over the granulations at the seat of fracture, but that the upper part of the wound was cicatrising, and on the 1st of December only the seat of fracture was treated antiseptically. Pulse 92; temp. 98·4. On the 3rd of December the whole space between the fractured extremities of the bones was completely occupied with the granulations, which were slightly elevated above the surrounding skin, and it was found necessary to compress them by the application of a piece of plaster. The chief part of this granular mass arose from the surface of the tibia, and as it had no tendency to form epithelium, it was from time to time touched with nitrate of silver and compressed by a bandage. A small cellular sinus now presented itself extending some two inches and a-half upwards, and another one about one inch and a-half downwards towards the heel; these were opened and injected with carbolic acid lotion. At this time, six weeks after the accident, although the wound had closed with the exception of a small raw granular surface, and the bones had become completely united by the granulation mass, yet little or no bone had formed, and the leg was flexible at the seat of the fracture. Union by bone did not take place until after the eighth week.

The points to be noticed in the case are—1. That no pus formed until the ninth day after the accident; 2. That after the ninth day the discharge which escaped from the wound and from the extensive cavity between the tibia and the severely lacerated muscles was only slightly turbid with pus corpuscles; 3. That throughout there was no fever, the temperature remaining about normal except on two days, and this elevation of temperature was found to be associated with pain and loss of appetite, apparently due to slipping of the apparatus and its consequent discomfort, for on reapplying the splint and rearranging the padding the discomfort was relieved, and the temperature and pulse lowered; 4. A slight local elevation of temperature, accompanied by pain, was relieved by the local application of ice.

Prof. Jevons, in the *Fortnightly*, asks how it is that people who can scarcely bear the word vivisection maim without compunction rabbits and birds; and how it is that a bull-fight is considered cruel, while a fox-hunt is called a manly pastime. These and similar questions have been asked before, but have not been satisfactorily answered.

CLINICAL SOCIETY OF LONDON.

SCLEROTOMY IN GLAUCOMA.

Mr. SPENCER WATSON read a paper upon this subject. He remarked that subconjunctival sclerotomy consisted in a section of the sclerotic, immediately above the upper margin of the cornea, by an incision which also opened the anterior chamber, the parts divided being the same as those cut in the first step of iridectomy, save and except the conjunctiva. The incision was made by means of a narrow Gräfe's cataract knife, the only parts of the conjunctiva divided being those punctured at the points of entrance and emergence of the blade on the temporal and nasal sides of the cornea respectively. Two cases were read in full, and a third briefly referred to. They were all successful. The three patients were exhibited and demonstrated satisfactorily the efficacy of the operation in reducing glaucomatous tension, though in one of the cases a second operation had been required. Mr. Watson preferred sclerotomy to iridectomy in all cases in which anæsthetics were inadmissible, and particularly in cases of chronic or subacute glaucoma with atrophic wasting of the iris and permanent dilation of the pupil. The advantages of sclerotomy were—1, the rapidity with which it could be executed; 2, the absence of bleeding into the anterior chamber; and 3, the absence of risk of injuring the lens, especially in those cases in which the iris was drawn backwards and attenuated, as in old standing cases of chronic glaucoma. He considered that there would be no risk in iridectomy of producing a staphyloma, but there would be in sclerotomy, and staphyloma would be likely to set up irritation, and so induce sympathetic ophthalmia in the other eye. Experience would show which cases were best adapted for sclerotomy and which for iridectomy.

GLYCOSURIA FOLLOWING CEREBRO-SPINAL CONCUSSION.

Dr. BUZZARD related the case of a tradesman, aged 41, who descended from a train one night in January, 1875, alighting on the permanent way instead of the platform. The depth of this unexpected step was three feet, and he came with great violence on to the soles of his feet. There was a numb feeling in his neck at first, and a week afterwards loss of power in both legs and one arm. Two months after the accident, when Dr. Buzzard saw him in consultation with Mr. Shurlock and Dr. Charles Bennett, there was still some want of power in his extremities, tremulousness of the jaw, thickness of utterance, and a somewhat rapid pulse. These symptoms pointing to a lesion of the medulla oblongata, Dr. Buzzard suggested that sugar would probably be found in the urine; and this was found to be the case on examination. The amount of sugar, which was small at first, increased during the twelve months following. The presence of the sugar was constant, except for a few weeks whilst the patient was on a restricted dietary. The patient made a claim against the railway company, and the cause came on for trial last November, but was settled when he had been examined by the company's medical advisers. At the present time, the muscular symptoms had almost entirely disappeared, but the urine was still saccharine, and, when recently examined by Dr. Pavy, contained nearly nine grains to the ounce. The important question from a medico-legal point of view was of course whether the glycosuria resulted from the fall, or had existed previously. There was no distinct history of illness preceding the fall; and the plaintiff's weight, which when he was first examined was a fair one for his height, decreased by one stone during the first three months that he was under observation. Had this rate of decrease been going on for any length of time, Dr. Buzzard pointed out, the man must have been at quite a recent period a much bigger person than the evidence showed that he had been. Dr. Buzzard attributed the glycosuria to the injury, described the probable mode of its production, and raised the question whether saccharinity of urine of traumatic origin, when it was not a transitory symptom, developed into typical diabetes.

Dr. A. S. DONKIN thought it unfortunate that there was no evidence concerning the condition of the urine before the accident as without it there was no proof whether or not the glycosuria depended upon the accident. When glycosuria was produced in animals by experiment it was not of long duration. He had only known one case under his treatment which could have resulted from an injury. He looked upon diabetes not as a neurosis, because he had found it so amenable to a dietetic treatment, and only to that treatment.

Dr. PAVY considered diabetes as a neurosis and associated with affections of the nervous system. He thought that Dr. Buzzard's case assisted to prove that diabetes was connected with injuries of the nervous system. Dr. Buzzard's case was he considered one of glycosuria which was quite different from idiopathic diabetes. He referred to the case of a man who fell upon the back of his head, and soon after became the subject of glycosuria, from which he recovered on being placed upon restricted diet. In many cases of true diabetes, especially in young people treatment was of no avail and they terminated fatally. Patients had been under his care who had been elsewhere treated dietetically and had been said to be cured, but he had found them not cured.

Sir WILLIAM JENNER said there was not sufficient evidence that the glycosuria resulted from the injury. The man was previously in ill-health—possibly owing to glycosuria. He agreed with Dr. Pavy in the utter worthlessness of all known treatment in some cases of diabetes. Some cases were curable, but he was quite unable to say in what consisted the difference between curable and incurable cases. He referred to the case of a gentleman whose glycosuria was always amenable to treatment but recurred after any error in diet, and yet that gentleman had lost a son from the same disease. Just as in neurotic affections, neuralgia for instance: articles of diet would produce the neurosis, so Sir William considered diabetes a neurosis sometimes amenable sometimes not amenable to treatment.

Dr. BUZZARD knew nothing of the family history of the case.

PATENT DUCTUS ARTERIOSUS, ATTENDED BY A THRILL AND TWO MURMURS.

Dr. HEADLAM GREENHOW related the case of the patient, a girl, aged 17, who had been treated in the Middlesex Hospital. Several members of the girl's family had died of phthisis, and she herself had had a cough from childhood, which had, for about a year before her admission to the hospital, become much more severe. During that time, also, she had been losing flesh, had had shortness of breath, and oftentimes hæmoptysis. The catamenia had scarcely appeared. The girl was small and ill-nourished; had a contracted chest, clubbed fingers; pulse 130, and temperature 99·6 deg. There was marked dulness upon percussion over the upper part of the left lung, and gurgling and pectoriloquy were heard at the same region upon auscultation, with tubular breathing at the right apex; and moist crepitation throughout the remainder of both the lungs. The visible area of the heart's impulse was extended; and in the second, third, and fourth left intercostal spaces close to the sternum, especially the second, a purring thrill was heard. In this same space also a harsh systolic bellows murmur was heard, followed by a continuous humming murmur, which was audible throughout the remainder of the period of the heart's action until the bellows murmur recurred. The patient's phthisical symptoms abated somewhat, and she then left the hospital; but was readmitted a fortnight subsequently, with crepitation throughout the lungs, of which she shortly died. At the necropsy, the left lung was everywhere adherent to the parietal pleura; and in its upper lobe were numerous cavities, evidently of old date; elsewhere there was lobular consolidation. A large mass of indurated glands closely surrounded the pulmonary artery and arch of the aorta. The upper part of the right lung was consolidated. The right ventricle of the heart was enlarged, and its walls were thick and firm. The right auricle was also dilated. The foramen ovale was closed. In the pulmonary artery, close to its bifurcation, was a small orifice, of the size of a crowquill, its margin being almost surrounded by a valve-like fold of the lining membrane. This was the aperture of a patent ductus arteriosus, about a quarter of an inch in length, that opened into the lower wall of the aorta just beyond the left subclavian artery. The aortic opening was about double the size of the other opening, and was also guarded by a reduplication of the lining membrane. The left cavities of the heart were natural; the valves were normal. The aorta was somewhat constricted just below the subclavian artery. Dr. Greenhow remarked that it had been difficult, during the patient's lifetime, to form any conclusive opinion as to the exact cause of the thrill and the two murmurs, though they were (from their situation) evidently connected with the pulmonary artery, but not with narrowing of the pulmonary orifice. It is true both aortic and pulmonary orifices were

smaller than natural; but they maintained their normal ratio to each other, and also probably to the diminutive stature and imperfect development of the patient. Dr. Greenhow had thought the thrill and murmur were due to pressure upon, and displacement of, the pulmonary artery, resulting from the chronic lung-disease. As regards the humming sound, he could form no satisfactory theory during life; but it appeared now to have been probably produced by the passage of blood from the aorta to the pulmonary artery through the open ductus, and over the semi-lunar valve-like folds which surrounded its extremities. That the stream took that direction, he thought was evident from the absence of cyanosis, and from the larger size and funnel-shape of the aortic orifice of the duct. Dr. Peacock had seen the specimen, and had suggested that the ductus arteriosus might have been prevented from closing by the constriction of the aorta beyond the left subclavian artery; in which situation the vessel, in such cases, was sometimes found entirely obstructed.—In answer to the President, Dr. Greenhow stated that there was no possibility of the humming sound having been produced in the vena cava, as it was limited to the second left intercostal space.

MEDICAL SOCIETY OF THE COLLEGE OF PHYSICIANS OF IRELAND.

THE Society met on Wednesday March 8th,

Dr. GORDON, President, in the chair.

Dr. T. W. GRIMSHAW communicated a

CASE OF ABDOMINAL ANEURISM TREATED BY ACONITE AND REST.

The patient was an engine fitter, aged 34, and was admitted to Steevens' Hospital on April 7th, 1875, with a large tumour occupying the upper part of the abdomen, filling the epigastric region. The tumour was pulsating violently, the impulse having the well known expansile character of an aneurismal sac. There was a loud bellows murmer audible over the tumour and along both sides of the spine behind; the tumour was quite immovable either vertically or from side to side. The feel and appearance of the tumour were positively alarming, and the patient complained of much pain in it, of oppression in the abdomen, and intense pain in the back, especially to the right side of the spine in the lower dorsal region, with pain and numbness in the legs, and occasionally swelling of the feet. At night he got frequent and severe attacks of pain and pulsation in the tumour, waking him suddenly with the belief that he was going to die. The patient's sleep was generally interrupted by these attacks, which were aggravated when his bowels were less free than usual. The bowels were tolerably regular, but the intervals between motions rather longer than normal. There was a slight tendency to diarrhœa on one or two occasions, but at no time was it found necessary to treat him for any bowel derangement. The pulse presented nothing remarkable, and except during the above-mentioned attack, of pain, did not depart from the normal frequency and force. There was little difficulty in diagnosing the disease to be abdominal aneurism, either of the aorta itself, or of one of its larger branches. It was believed to be aortic. The aneurism was one of great size, and it was evident that the patient's life was in imminent danger. Mr. Tufnell's method of treatment was suggested, but as there was no doubt that the patient would not submit to such rigid routine, it was decided to adopt a somewhat modified plan, which consisted of rest in the recumbent position, the patient being allowed to turn on his side and to move about to a considerable extent, but in the recumbent position. From the beneficial, though not successful results which he had experienced from the use of aconite in two cases of thoracic aneurism, he determined to use the drug in this case, believing that by its use accompanied by complete rest, the life of the patient would be prolonged for some time, and possibly, though improbably, a cure effected. Five minims of the tincure of aconite were—with the diet before mentioned—ordered every three hours, and this continued for a week, the drug meantime developing its specific effects. The pulse was now very slow and weak, and the limbs had a tendency to become cold, but the pulsation of the tumour much less than on admission. However as at this time the symptoms of poisoning were unpleasantly marked, the dose of aconite was reduced to one-half, and for three months the treatment was continued, the plan adopted being to interrupt the administration of the drug whenever tingling sensations were felt by the patient at the extremities. Meanwhile the improvement in the condition of the tumour was steady, but scarcely noticeable, from day to day. In July a considerable improvement had taken place in the tumour, but the patient's general strength was failing, and his diet was in consequence increased by the addition of meat and stirabout. On the 24th of August, having previously been diminished, the aconite was abandoned and Parrish's syrup substituted. The tumour continued to decrease in size, the symptoms steadily diminished, and the murmer also became almost inaudible. The tumour was examined on November 7th, and no murmur was heard; its bulk was probably not one-third what it had been when the patient was admitted, but there was still some pulsation. Another examination was made on November 14th, when it was found that pulsation ceased, the tumour felt solid, and the patient did not complain of pain. The patient left hospital on December 8th in good general health, but, complaining of slight pain in his back and some weakness of his limbs. Dr. Grimshaw said he saw the patient in February, 1876, when on examination he found the tumour solid, without pulsation or murmer. In none of the superficial arteries at the ankle could pulsation be detected, and at the popliteal and femoral arteries it was feeble, and the patient complained of constant coldness of the feet. Dr. Grimshaw said in conclusion that he fully appreciated the feebleness of conclusions drawn from single cases, but nevertheless he believed that the result of the case he had detailed was suggestive of a mode of treatment of internal aneurism, which might probably prove successful in other cases. From what he had both seen and read of the result of Mr. Tufnell's plan of treatment, he was strongly of opinion that the combination of the aconite with Mr. Tufnell's method of treatment would give the best chance of a favourable result in these cases. He (Dr. Grimshaw) knew that the sugges tion of the employment of aconite was not an original one, but he did not know of any published case where the symptoms appeared substantially to diminish as a result of the use of aconite, nor did he know of a case where cure had followed the employment of the drug.

The PRESIDENT said he did not know of any case in which aconite had been used so steadily and in such large doses as Dr. Grimshaw had alluded to. This disease was one of the hardest to diagnose. There could be no doubt of the success of the treatment that had been described.

Dr. HENRY KENNEDY said the subject was one of great importance. With regard to the result of that single case, they should never forget the fact that aneurisms, no matter in what region of the body, were capable of cure *per se*. There were plenty of examples on record of cures even in the brain; and if a person died of aneurism of the arteries of the brain, as they frequently did, it was not from the bursting of the aneurism, but from the aneurism causing disease of the cerebral structure around it. Under peculiar circumstances, the disease was capable of curing itself, without, he might say, any effort being made on the part of the physician or surgeon to cure it. Dr. Grimshaw's case was an important one, as bearing in a particular way on the treatment of the disease. In alluding to Mr. Tufnell's method of treatment, of position and restricted diet, Dr. Kennedy said he did not think it necessary to carry the starving plan quite so far as Mr. Tufnell did. Dr. Grimshaw's case appeared to have involved the spine, for the symptoms of weakness of the limbs pointed to the engagement of the vertebræ. The non-mobility of an aneurismal tumour in different positions of the body was an important point in the diagnosis of abdominal tumours.

Dr. GRIMSHAW said, in the course of his reply, that in his case the patient felt a tingling in the arms as well as in the legs, but the latter might have resulted from the backward pressure of the tumour. He believed the man's spine was seriously injured, and doubted if he ever would recover from that affection. The murmur had, however, quite subsided. The patient was in the hospital for nearly a month before both pulsation and murmur had ceased.

Mr. LAPPER (by permission of the Council) read a paper

ON THE ANTISEPTIC POWER OF SALICYLIC ACID AND CERTAIN OF ITS COMPOUNDS COMPARED WITH OTHER ANTISEPTICS THERAPEUTICALLY CONSIDERED.

Dr. FOOT said that, looking at the subject of antiseptics from a medical point of view, he thought that, although salicylic acid, when rigidly tested, might prove inferior to some of the other agents in the list, yet it might be practically more useful from the readiness with which it could be procured, and the facility with which it could be administered. On this account he had at once employed it in a variety of cases in

which its freedom from disagreeable taste or smell and absence of causticity made it more eligible than carbolic acid.

The PRESIDENT alluded to a case of empyema with pulmonary fistula which was dressed daily with salicylic acid spray. The purulent matter decomposed very rapidly, but the acid produced a marked effect in delaying any decomposition for ten days in a portion of the fluid to which it was added. The case recovered faster than any similar one he had ever before seen.

Dr. DUFFEY thought there was little doubt now as to the value of salicylic acid as an antiseptic and deodorant. He (Dr. Duffey) was at present using the pure acid in a case of chronic otorrhœa in a young child. By sprinkling the acid on a thin layer of finely-carded cotton-wool, and rolling this up in a small pledget, he was enabled to introduce a considerable quantity of the acid into the meatus, and thus keep it in contact with the source of the discharge. So far, the result was satisfactory, the discharge being considerably lessened, and its fœtor entirely removed. The application did not cause any pain or irritation. Salicylic acid appeared to have a great many advantages in addition to its antiseptic properties. Dr. Ewald, of Berlin, in a paper published in this month's *Practitioner*, states that his experience—extending over upwards of one hundred cases, mostly of enteric fever—proves the superiority of salicylic acid over all other known antipyretics. It has also been recently recommended in the treatment of acute cases of rheumatism; and Stricker reports that it has a most marked and certain effect in reducing the fever and relieving the articular pains of this disease in an incredibly brief space of time.

Mr. H. G. CROLY then related a case of idiopathic glossitis, after which the Society adjourned.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, MAY 17, 1876.

THE COMING MEETING OF THE GENERAL MEDICAL COUNCIL.

BEFORE our next number is issued the Medical Council will have assembled for its Session for 1876, too late to be of much use for legislative purposes, but early enough for the discussion of the routine of the session.

After the introduction of the four new members of the Council who have been appointed since its last meeting, the President, Dr. Acland, will deliver his opening address, or speech from the throne. This done, and committees having been appointed, the Council will proceed to elect a treasurer in place of Dr. Bennett, and will receive the resignation of the Registrar, Dr. Hawkins, and enter on the discussion of the duties and emoluments of the new officer. It has been suggested, we believe, that a non-medical man might be appointed, a job which, if perpetrated, would be an outrage on sense and propriety. It is hardly to be conceived that a non-medical man would be likely to possess a superior knowledge of the duties required of him, and it would be an unmerited slight to the profession if the Medical Council were to choose for their executive officer a non-medical person. The principal debates in this year's meeting of the Council will arise on the reports of visitors of examinations, on the conjoint scheme of examination for England, and on the "woman doctor" question, which will be brought under notice by means of a letter from the Obstetrical Society of London to the President. The Council will have before it for discussion the responses of the following licensing bodies to the Visitors' reports—The two London Colleges, the Universities of Oxford, Edinburgh, Aberdeen St. Andrews, and Dublin, the College of Physicians of Ireland, and the Irish Apothecaries' Hall, The reply of the latter body to the uncompromising strictures of the visitors cannot but be interesting reading.

The business which was before the Executive Committee the week before last, and which we epitomised in this journal on that occasion, will also be discussed. The question of certificates of proficiency in vaccination, the distribution of the "Medical Register" to registrars of births and deaths. Mr. Cowper-Temple's Bill for the legalising of the foreign diplomas of lady doctors. Mr. Edward Gibson's Bill for the opening of Irish county infirmaries to all qualified surgeons, and for the registering of the State Medicine degree of Dublin University.

All these will be the subject of debate. Last and most important will come the English conjoint scheme which, despite the prognostics of the no-reform party, has assumed a practical form, and may almost be regarded as a settled affair. The coming meeting promises to be a lively one, and we shall do our best to inform our readers as to its proceedings.

THE METROPOLITAN ASYLUMS BOARD.

IT is very seldom that the work done by "Boards" is of so satisfactory a nature, or is so deserving of public attention, as that which can be placed to the credit of the Metropolitan Asylums Board; and it is all the more satisfactory to be able to make this statement, considering that when this board was first established under Mr. Gathorne Hardy's Act of 1867, the London parishes were almost unanimous in protesting against the extravagance of building large asylums for the sole reception of patients suffering from fever, small-pox, or imbecility. Actuated by the short-sighted policy and the prejudices which so often characterise the discussions of our parish authorities, the latter could not see why the poor imbecile, or the patient lying prostrate with fever, should not, as heretofore, be treated along with the other inmates of our workhouses. Nor can we regret that their protests were in vain, and that buildings have been erected which are alike a credit to humanity and to science. We say "to humanity" advisedly, for surely it is with some feelings of shame we must confess that, in this great metropolis, with its from three to four millions of closely-packed

human beings, there was, before the Board commenced its work, only one fever hospital, namely, the old institution in the Liverpool Road. However, fresh asylums were built, and, judging from the review which the chairman of the board, Dr. Brewer, has made of the work done during the five years it has been established, it is very gratifying to find that not only was the board able to cope with the emergencies entailed by an exceptionably severe epidemic, and to afford more humane and rational treatment for the imbecile poor, but it has had, through its asylums, a very marked effect in lessening the attacks of zymotic disease in the metropolis. The board has established two large asylums for the treatment of epidemic diseases, one at Stockwell, the other at Homerton; while in case of emergency it has secured sites for more asylums at Fulham and at Deptford. Even for the treatment of imbeciles, of whom the board have as many as 5,000 under its care, there are at present four asylums—one at Caterham, capable of holding 2,000; one at Leavesden; a temporary one at Hampstead; and a temporary one at Clapham for children. Scarcely had the board commenced operations before the need of such an establishment was forcibly demonstrated, and its energies taxed to the very utmost. An epidemic of typhus fever had broken out, and they were obliged, with the help of the London Fever Hospital, to erect temporary buildings for the isolation and treatment of the patients. Soon after that, in 1871, they had to cope with the virulent epidemic of small-pox which occurred in that year, and during which more than 2,000 patients were at one time under their care. "This epidemic," observes Dr. Brewer, "which rose to its crisis at the period when the managers were constructing their permanent hospital, while it tested their resources to the utmost, furnished them with much valuable experience touching the treatment of the disease and the management of their establishments, of which they were not slow to take advantage; . . . and the combined experience of the several hospitals in regard to vaccination was collected by a special statistical committee, and extensively published."

There are no circumstances under which the services of this board would be so indispensable as in the event of an invasion of the metropolis by cholera. In fact, in 1873, when there was some fear of such an epidemic occurring, the board undertook to deal with the epidemic, should it break out, but with the understanding that they should not be considered "responsible for meeting any outbreak occurring in the whole of the metropolis, or as relieving the local authorities of the responsibilities attaching to them in the event of an outbreak." And, as it is shown that the isolation of typhus fever cases by the board led to a marked diminution of that disease, we may expect that a like care and vigilance on their part would, in conjunction with other measures and the help of the local authorities, check the spread of the still more dreaded cholera pestilence. The fact that cholera radiates more from infecting neighbourhoods, or from certain foci of infection, is not likely to be lost sight of by the board, who, in the event of a future invasion of cholera, will no doubt act in the same manner as they did in the case of the typhus epidemic, and at once direct the attention of guardians to any quarter from which they may receive into their asylums patients afflicted with that dreadful disease.

At all events, the amount of work done in so short a time, and the success resulting from it, are very remarkable, and the exertions of the board in the interests of the public and of the unfortunate patients themselves are such as to deserve the hearty sympathy and support of all those who are interested in the good and honest management of our metropolitan charities. Even the devotion shown by the members of the board in the performance of their duties shows the zeal with which they carry out the task committed to their care; and when we hear that the chairman, Dr. Brewer, was himself stricken with fever during the epidemic of 1870, and that the vice-chairman, Mr. Suter, was, under the same circumstances, attacked with small-pox, our sympathy for them and their work is all the more due to them; while we are insensibly reminded of the self-sacrificing devotion that has been shown under similar trying circumstances, and of the penalties that have been incurred, by many of the staff attached to our general hospitals.

Notes on Current Topics.

The Health of Hastings.

HAVING on one or two occasions recently referred to the water supply of this important health resort as likely to affect the wellbeing of its inhabitants, and of the many patients sent there by the profession, we are happy to accede to the request of the medical officer of health to give space to the quarterly report issued by him last week, in order to place before our readers a fair and official statement of the health of the town at the present time.

"During the quarter ending March 31st, there were registered the births of 142 males, and 117 females, being a birth-rate of 29·6 per 1000. There were only 155 deaths during the quarter, against 182 in the corresponding one of 1875, and 177 in 1874. Of these, 30 were between the ages of 60 and 80, and 7 80 and above. There were six deaths from the zymotic class of disease, viz.: Variola, 1; diphtheria, 1; measles, 3; typhus, 1. Constitutional diseases caused 30 deaths, viz.: Cancer, 4; tabes, 3; phthisis, 22 (eight visitors), hydrocephalus, 1. Eighty-eight deaths are attributed to local diseases, viz.: Diseases of the brain and nervous system, 24; of the organs of circulation, 16; respiratory organs, 28; digestive organs, 10; urinary organs, &c., 10. Developmental diseases caused 24 deaths, chiefly from premature birth and diseases of nutrition (8), and old age, 13.

"The past quarter, therefore, has been distinguished above its corresponding predecessor of 1875 by a higher birth, and a lower death-rate. Allowing for the usual increase of population, the death-rate per quarter is 17·7 per 1000 per annum, and if the deaths of visitors (35) be excluded, we have the remarkably low death-rate of 13·71; and even this might legitimately be lowered to 12·9, as seven of the deaths occurred in public institutions outside the borough. There are few towns in England can show such a low death-rate. That Hastings and St. Leonards will compare favourably with any seaside resort, both in respect to mortality and sickness during the term mentioned, is my firm belief. The mortality is shown above, and the small amount of sickness in these towns of any serious character is proverbial. Of the few zymotic cases of sickness, there has apparently been no exciting local cause productive of them, and several of the cases were imported."

Chromic Acid for Warts.

THREE or four applications of this acid says *l'Union Médiiale*, will cause the disappearance of warts, however hard, large, or dense they may be. The application gives rise to neither pain, suppuration, nor cicatrices, the sole inconvenience being the production of a dark brown colour.

Sewage in the London Water.

AT the monthly meeting of the Teddington Local Board, the clerk, Mr. J. Russell, reported that the Thames Conservators had that day served notices on the sanitary authorities of all parishes on the banks of the Thames discharging sewage into the river to discontinue such discharge, otherwise proceedings would be taken. By far the larger part of London, and also a vast number of other towns and villages receive their water supply from the Thames, and above the neighbourhood from which most of the water companies have their intake, the excrement of some eighty thousand people is discharged daily into the river. There are no means of ridding the water of this sewage excepting some of the largest solid particles, which are separated by filtering through sand; so that all the water distributed through the pipes of those companies which draw from the Thames is tainted with sewage. The quantity may be small, but still it is polluted water, oftentimes perhaps containing germs from the excrement of fever patients.

Up to the present time the people of London have not even murmured at being compelled to drink sewage-polluted water, though doubtless many have succumbed to fever and diarrhœa, so induced. Thanks to the press, both the people and the authorities have been stirred up to take action in the matter, and the result has been that the Thames Conservators have issued a notice that in future no parish will be allowed to pour its sewage into the Thames. It is a matter of congratulation to those who are supplied with Thames water that, though at times the water may still be turbid, or may swarm with animalculæ or even fish, yet it will at least be free from sewage.

The Public Press and Quackery.

IT will be a long time before the lay press will exert themselves to overthrow quackery. Many country papers are actually supported by the advertisements of quack doctors, dentists, quack medicines, &c. We are glad to see that some of the lay press are alive to the fact that, though they may gain by such advertisements, the public suffer. The *Leisure Hour* has inserted an interesting little anecdote, which, whether true in its details or not, is an illustration of cases which occur daily in the hands of quack dentists, and its publication will serve to warn the readers against a class of practitioners who constantly make the public to suffer both in purse and in person:—

"The following incident known to us may serve as a warning against some of those who prey upon the public. General ———, an old Indian, and a wealthy man, has a stick with a gold top, which he often shows, with the question, 'What do you think that bit of gold cost?' After silence, or a wide guess: 'Why, sir, it cost me a hundred guineas!' And then he tells us how, on seeing an advertisement in the *Times*, he was attracted by its liberal promises, and pleased with its frankness of offering 'advice gratis,' and so on. His case, he was told, was one of extreme difficulty, but might, with great skill and care, be managed. Ignorant of the ways of these gentry, the general submitted himself meekly to the operator, who managed him as rich patients are usually managed. A duplicate set was prepared, which the general was told was the usual practice, when not otherwise specified. The general began to think there was 'sharp practice,' when the dentist stated that credit was never given, but that payment must be made before the teeth were taken away. On writing the cheque for £100, the watchful trader said his charge was a hundred *guineas*, and the general had to pay that sum. After some trial, the teeth were found utterly unserviceable, causing intense misery; but rather than have anything more to do with the advertising dentist, the general went to a qualified practitioner. Being properly fitted by him, the gold of the old sets was melted to make the top of the stick, which he displays good-humouredly as a monument of his own folly, as well as a warning to others."

Contaminated Wells.

AT Guildhall, the owner of premises in Queen Victoria Street attended in answer to a summons taken out by the Commissioners of Sewers, charging him with having on his premises a well for domestic purposes which was impure and totally unfit for household use. Four analyses of the water had been made, the average result showing that it contained 99·1 grains per gallon of solids, against 17·0 of the New River Company; 9·2 grains per gallon of chlorine, against 1·2 of the New River Water; 8·20 parts per million of ammonia, against 0·03 of the New River water, and 1·9 of albuminoid ammonia, against 0·06 of the New River water.

It is important that the public should know that, in consequence of the number of burial-grounds, sewage contamination, &c., the subsoil in most parts of London is so impregnated with impurities that the water in nearly all the wells is, by permeation of these impurities, rendered unfit for domestic purposes.

In this case, the owner of the premises gave a guarantee that the water of the wells should not be used for drinking purposes.

The London College Primary Examination.

THE *Students' Journal* in its last publication remarks upon the fact that the examiners at the College of Surgeons dealt rather hardly with the candidates at the last "primary" examination. Nearly one-half were "plucked." It seems strange that such a large proportion should fail, spite of the "test" examinations, and all the pains that are taken with the candidates. "In some hospitals," says our contemporary, "anatomy is well taught, but practical physiology is much neglected. Numbers of otherwise very good men have, I am told, failed lately, because they know little or nothing about microscopic anatomy."

Memorial to the Late Dr. Parkes, F.R.S.

AT a meeting of Army Medical Officers, held in the Mess-room at Netley, 20th April, 1876, the Principal Medical Officer in the Chair, the following resolutions were unanimously agreed upon:—

1. Proposed by Surgeon-General Longmore, C.B., seconded by Surgeon-General Maclean, C.B.: "That it is desirable to establish a permanent memorial of the late Dr.

Parkes, Professor of Hygiene in the Army Medical School."

2. Proposed by Surgeon-Major J. Coates, M.D., seconded by Surgeon-Major G. Pain : "That the memorial consist of a portrait, to be painted by an eminent artist, which should be placed in the Mess-room of the Head-Quarters of the Army Medical Department, whether at Netley or elsewhere ; and of a replica of the bust of Dr. Parkes now at University College, to be placed in the Lecture-room of the Army Medical School ; and, further, if the fund collected admit of it, the foundation of a Parkes Scholarship, or Prize, to be competed for in the Army Medical School."

3. Proposed by Surgeon-Major J. H. Porter, seconded by Surgeon J. O'Reilly, M.B.: "That all Medical Officers in the Army, Naval, and Indian Public Services be requested to subscribe ; and that contributions be also received from any other friends and admirers of Dr. Parkes, who wish to join in the memorial."

4. Proposed by Surgeon-Major D. Cullen, seconded by Surgeon-Major Rattray, M.D.: "That the subscription from Officers be limited to one day's pay."

5. Proposed by Surgeon-Major J. Coates, M.D., seconded by Surgeon-Major W. M. Webb : "That the following gentlemen be appointed to act as a local committee to carry out the objects of the meeting:—President—Surgeon-General Longmore, C.B. Members—Surgeon-General Maclean, C.B.; Deputy-Inspector General J. D. Macdonald, F.R.S., R.N.; Surgeon-Major J. Coates, M.D.; Surgeon-Major J. H. Porter; Surgeon-Major W. M. Webb; Surgeon-Major D. Cullen, M.D.; Surgeon-Major C. Rattray, M.D.; Surgeon-Major W. Cherry ; Surgeon-Major F. Welch ; Surgeon A. B. Robinson ; Surgeon J. O'Reilly, M.B.; Dr. Aitken, F.R.S.; Surgeon-Major C. D. Madden; Surgeon-Major G. Pain ; Surgeon-Major T. M. Bleckley, M.D., C.B.; Staff-Surgeon W. F. C. Bartlett, R.N.; Surgeon-Major R. Waters, M.D.; Surgeon-Major T. W. Wright ; Surgeon-Major S. G. White, M.D.; Surgeon J. Fleming, M.D.; Surgeon R. Bowman, H.M.'s Indian Medical Service ; Surgeon A. S. Lethbridge, H.M.'s Indian Medical Service. Treasurer—Surgeon-Major F. S. B. F. De Chaumont, M.D. Secretary—Surgeon G. E. Dobson, M.B."

A Small-pox Outbreak.

An alarming outbreak of small-pox has occurred at Bulkington, a small village in Warwickshire, about six miles from Coventry. The disease is said to have been imported from Manchester by a young man, and in spite of all precautions has spread rapidly through the v illlage. all the schools have been closed in consequence, and handbills have been issued cautioning the public not to go into the locality.

The New Medical Warrant.

Since our last issue our attention has been called to certain matters of detail affecting the conditions under which candidates are invited to enter the army, and which, if not altered, will, we fear, deter many from coming forward. We have been advised that under clauses 10, 11, and 12, an officer who may not serve five years, and is permanently disabled from ill health contracted in and by the service, to resume his duty, receives no compensation whatever. Such cases would possibly be of rare occurrence ; still, when they do occur, some provision should have been made for the contingency. A very general objection has also been made in the schools against the clause limiting the selection for promotion to *six* annually. The general feeling seems in favour of the clause being altered so as to allow continuance in the service to be the rule rather than the exception. We have already expressed our opinion that the clause as it now stands must become a dead letter. In the meantime, the War Office by such unfortunate omissions risks the success of a scheme which has as a whole many points of excellence to recommend it. Short service, with the non-selection of the minority whom it might not be deemed advisable to retain in the department, would, in our view, meet the difficulty to which our attention has been directed. It has also been objected that the reduction of the maximum of daily pay receivable from 27s. to 25s. will reduce the rate of voluntary retirement after twenty-five years' service in the executive ranks to a lower figure, seven-tenths of 25s. being less than seven-tenths of 27s. The question of Indian pay and allowances, and of having two scales of pay for the older and newer officers, must lead to jealousies which it would have been more prudent to allay. There are matters of detail, not very seriously affecting the general principle of the new warrant, which are worthy of the consideration of her Majesty's War Office.

Science at South Kensington.

In a recent issue we referred to the exhibition of scientific apparatus in preparation at South Kensington Museum which was shortly to be opened. On Saturday last her Majesty the Queen, accompanied by the Empress of Germany, visited the building, and after a short inspection formally declared the exhibition open. The collection is of very varied character, and if we except one or two branches is fairly representative. Its utility, however, is not to be limited to a mere display of models; conferences of allied subjects are being arranged, and much valuable knowledge is expected to accrue therefrom. This week conferences in the Section of Physics are being held, the opening address to which was delivered by the President of the Section, Mr. W. Spottiswoode, M.A., F.R.S. Papers are also expected from Mr. W. Huggins, D.C.L., F.R.S., "On the present State of Spectroscopic Research relating to the Stars and Nebulæ ;" Mr. Norman Lockyer, F.R.S., and Captain Abney, R.E., "On Spectroscopic Research in Solar and Molecular Physics ;" M. le Professeur Soret, "On a Spectroscope with a Fluorescent Eyepiece ;" Professor Bellamy Clifton, M.A., F.R.S., "On Interference, and Instruments for the Measurement of Optical Wave Lengths ;" Mr. H. C. Sorby, F.R.S., "On the Original Form of the Spectrum Microscope and the various subsequent Improvements and additional Apparatus ;" the Earl of Rosse, D.C.L., F.R.S., "On Zollner's Photometer ;" Professor Sir W. Thomson, LL.D., F.R.S., "On the Principles of Compass Correction in Iron Ships ;" M. Sarasin-Diodati, "On De la Rive's Researches in Static Electricity ;" and the President (Mr. W. Spottiswoode, M.A., F.R.S.), "On some recent Forms of Polariscopic Apparatus."

Dissemination of Disease by Milk.

The Eagley and other epidemics have established, outside the possibility of doubt, the fact that disease may be, and probably has, very frequently been introduced into families through the agency of "the cow with the iron tail," whose patronymic is "Simpson." It certainly ought to be one of the privileges of a free Briton to get water and not

sewage as a diluent for his milk, especially as he pays 5d. a quart for the luxury; but the milkmen don't appear disposed to indulge the free Briton to that extent, if we may judge from recent revelations in the London Police-courts. We observe that at the Worship Street Police-court, last week, the vestry clerk of Shoreditch attended to support summonses taken out against several dairymen and cowkeepers for having on their respective premises foul wells, containing water in such a state as to be a nuisance and injurious to health. Samples of the water had been submitted to Dr. Stevenson, Guy's Hospital, and to Professor Wanklyn. On analysis, the water was found to be highly polluted, and both Professor Wanklyn and Dr. Stevenson agreed in describing it as "diluted sewage." Its condition was illustrated in court; a sample of the well-water, and another from the New River mains, were put into tubes by Dr. Stevenson, and the different appearance was then observable by the naked eye. Nessler's test was then applied, which speedily turned the well-water sample to a thick yellow colour, with a deposit at the bottom of the tube; whilst the New River sample was perfectly unaffected. The magistrate made an order for the closing of the wells within fourteen days.

The report informs us further, that the water was "in use on the premises for all drinking and domestic purposes,' which we interpret to mean for the drinking of the customers and the domesticity of the dairyman. Perhaps the best solution of the difficulty would be to afford facilities for the dilution of milk at some central depôt, under the superintendence of Mr. Sclater-Booth and Mr. John Bright, the patrons of adulteration.

Army Medical Report, 1874.

The new volume, giving details upon the health of the army for the year 1874, is shorn of much of its former proportions, and become far harder as a book of reference. The army circulars, details of the various examinations, and statistical tables of individual diseases, have been altogether expunged, and the appendix only contains a few departmental papers.

From among 86,837 non-commissioned officers and men serving in the United Kingdom, there were 73,004 admissions and 735 deaths, the average number of men constantly sick throughout the year being 3,351. The ratios were in excess of those of the previous year, the causes of which are very clearly set forth. Affections of the constitutional group, and diseases of the digestive, respiratory, urinary, and cutaneous system preponderated largely over all other affections, the admissions in these several headings being as below:—

Constitutional	12,617
Digestive	10,636
Cutaneous system	8,947
Respiratory	7,770
Urinary	6,553

Dockyards and arsenals, and the large manufacturing twons, afforded the largest number of admissions. Dublin shows the lowest ratios of admissions and deaths:—

792·7 and 8·62 per 1,000 respectively. No group of stations was free from enteric fever. Outbreaks occurred in three stations—Newbridge, Dublin, and Limerick. In each of them there was evidence of the strictly local character of the epidemic. In every group there was an increase in the ratio of admissions from syphilis. The ratio per 1,000 constantly in hospital from primary venereal sores in 14 stations under the Act is 3·21, and 6.89 in 14 stations not subject to special legislation. 20,500 recruits were inspected by army medical officers during the year. 2,175 invalids passed through Netley Hospital. In Ireland the quality of the water supplied to the hospital at 16 stations was pronounced unfit for drinking purposes. Among recruits, diseases of the eyes and eyelids caused the largest number of rejections. Continued fever at Malta and the typhoid of temperate climes are stated to be one and the same disease, the intestinal lesions being similar in both.

In the great tropical dependency of Bengal the ratio of admissions and deaths was 1416·7 and 15·20 per 1,000 respectively, as against 840·7 and 8·79 respectively in the United Kingdom. Affections of the febrile group were largely in excess of all other diseases,—21,115 admissions out of 37,911 men. The average daily sick in each regiment was 55·59 per 1000. Dr. Watts' "Contribution to the Medico-Military Topography of the Persian Gulf and Valley of the Euphrates and Tigris" is the most practical and valuable of those contained in the appendix.

Chloroform Administration.

From time to time we observe statements in the daily press as to the criminal use of chloroform, which show that the public are under a mistaken impression as to the subject. Last week a young woman made an application at the Woolwich Police-court to order a parade of the whole of the Horse Artillerymen (about 1,000 in number) stationed at Woolwich. She stated that she came to see a relative in Greenwich, and two artillerymen spoke to her. She turned away from them, when one of them took out a bottle and poured something from it on a handkerchief, which he pressed to her face. She became insensible, and remembered nothing more till she was roused up at two o'clock yesterday morning by the military police, who found her lying on the grass on Woolwich Common, a distance of three miles from where the men accosted her.

The inference was, of course, that the soldiers had administered chloroform for a criminal purpose, and the same allegation has been put forward in many other instances. It seems necessary for the medical press to assure the public that such an administration of chloroform or ether may be said to be so improbable as to be almost physically impossible. Under the most favourable circumstances a patient cannot be anæsthetised in much less than five minutes, and frequently the time occupied by administration is considerably more. There is commonly an intoxications tage to be overcome, and, even if the anæsthesia were produced, it would be barely possible to keep it up while the patient was carried three miles. When a prosecutrix tells a tale of chloroform administration it may usually be assumed that she is unworthy of credit.

Physical Education.

In a recent article we referred to the necessity of adding physical education to military training. We are glad to see that the London School Board have taken the subject into consideration, and have determined to introduce it as a branch of public education.

We learn from the *Globe* that the London School Board have recently agreed to proposals emanating from Mr. Macgregor and the Rev. J. Sinclair. The former gentleman desires to see swimming recognised as a branch of public education, and suggests that lessons in the art, when imparted by a competent master, shall count as school attendance up to one hour a week, or ten hours in the year. Few will be found to contest the advisability of encouraging the rising generation to practise swimming. It is an anomaly, if not a scandal, that a pre-eminently maritime people like the English should be singularly deficient in the art. Even among sailors it is by no means uncommon to find complete ignorance of what, to them, is a vital branch of knowledge. There can be little question, therefore, that Mr. Macgregor's motion is right in principle, however difficult it may be found to give it practical effect, owing to the comparative paucity of swimming baths in the metropolis. The proposal of Mr. Sinclair is that "attendance of girls at lessons in physical exercises for not more than two hours a week and forty hours a year may in a day school be counted as school attendance." There cannot be much difficulty in carrying out this small amount of training, nor need the expense be otherwise than inconsiderable. Some simple gymnastic apparatus, adapted to the strength of growing girls, would be quite sufficient for all practical purposes. If this were provided in every day school, it would be easy enough to organise a regular course of training, up to the full number of hours allowed to count as school attendance. The necessity of some provision of this sort is beyond question. Not only would physical education render them more capable of doing hard work in after years, but whether called upon to perform hard work or not, physical education is an absolute necessity for the proper development of the frame.

Scarlet Fever in Melbourne.

It was hoped that scarlet fever, which was prevalent in Melbourne and the suburbs about four months ago, was abating, but it has lately broken out with new virulence in the country districts, and fatal cases are continually occurring in isolated spots supposed to be the healthiest in the colony, and safe from infection. The disease seems to work its way as readily in the pure air of the mountains as among streets and alleys, and often in a malignant form which carries off its victim in a day. It is proposed to again close the State schools. The churches are to set apart a day for humiliation and prayer, and Parliament is considering a Public Health Bill. In the meantime there is great mortality among children, and the poison is spreading itself unchecked by any effectual antidote.

Poisoned Milk.

The *Manchester Guardian* says that the sanitary authority at Oldham has discovered that the prevalence of typhoid fever in that town is in all probability largely due to the adulteration of the milk supply with poisoned water. The medical officer has presented to the Health Committee a report on the state of several dairy farms, which is even more disgusting than the revelations which followed upon the outbreak of typhoid at Eagley. During April there were 46 cases of typhoid fever in the town, and 17 deaths. The dairy farms in several cases appear to have been used as "tips" for town refuse and the offal of the slaughter-houses. The same reckless disregard of sanitary laws has just been exposed at Moss Side.

The Conveyance of Fever Cases.

We have on several occasions referred to the danger of spreading infectious diseases by the use of public vehicles. The case which came before the City magistrates on Saturday last, and in which a poor woman was fined £3 and costs was of a different character to those we usually hear of. According to the evidence of Dr. Alexander Collie, medical officer of Homerton Fever Hospital, two or three weeks ago the defendant arrived at the institution with her child in a cab, and the child, when admitted to the infirmary, was found by him to be suffering from scarlet fever. He gave notice to the cabman and to the police, and the cab was immediately taken in charge to the yard for disinfection. The witness added that the child had been in the German Hospital, Dalston. Dr. Collie added that it was right the magistrate should be made aware of the conduct of the authorities at the German Hospital. The defendant had been ordered to remove the child, but if she had carried it through the streets there would have been greater risk to the health of the public than by taking the cab, as the poor woman did. There was an ambulance kept by the parish for such cases, and the hospital authorities should have informed her how to get it for the conveyance of her child. There is manifestly gross carelessness somewhere in this case, and the sooner the hospital authorities purge themselves of the charge the better for their reputation. Here was an ambulance provided by the parish, yet no one, not even hospital authorities, to tell the poor woman of its existence.

Science in the City.

On Saturday evening the Lord Mayor of London entertained at a gorgeous banquet the representatives of science, English and foreign, together with a numerous and distinguished general company. Nearly 300 guests had the honour of invitation; Medicine and Surgery being represented by many distinguished members of the profession. Amongst those present were Dr. Hooker, the President of the Royal Society; Sir John Hawkshaw, President of the British Association; Sir George Airy, the Astronomer Royal; the Earl of Rosse; General Sir Henry Rawlinson, President of the Royal Geographical Society; Dr. Risdon Bennett, President of the Royal College of Physicians; Mr. Price, President of the Society of Apothecaries; Dr. Acland, President of the General Medical Council; Dr. Routh, ex-President of the Medical Society of London; Professor Duncan, President of the Geological Society; Professor Adams, President of the Royal Astronomical Society; Dr. Warren De la Rue,

Mr. Haywood, F.R.S., Mr. Sorby, Sir John Lubbock, Sir Joseph Whitworth, Sir Charles Locock, Sir George Burrows, Professor Tyndall, Sir Henry Cole, Sir Alex. Armstrong, Sir Henry Thompson, F.R.C.S., Sir Joseph Bazalgette, Sir Francis Hicks, Treasurer of St. Thomas's Hospital, Mr. Reed, C.B., Professors Ramsay, Erasmus Wilson, Stokes, Owen, Geikie, Carpenter, Morris, Story Maskelyne, Frankland, Guthrie, Goodeve, Percy, Warrington, Smyth, Edgar, Abel, Tennant, Reinold, Thistleton Dyer, Barrett, and Leone Levi, Prof. Blaserna, and many other distinguished foreign representatives of science; Drs. Birch, Bowman, Priestley, Gladstone, Swaine Taylor, Maudsley, George Johnson, Wilks, Wakley, Sedgwick Saunders, Lloyd Birkett, Brodie-Sewell, Farre, Garrod, and Sieveking; Mr. Prescott Hewitt, Mr. John Birkett, Mr. Spottiswoode, Mr. Huggins, Mr. Bentham, Mr. Glaisher, Mr. Frank Buckland, &c., &c.

Militia Surgeons.

We understand that pending the report of a committee now sitting, the appointment of militia senior surgeons has been discontinued.

Suppression of Illegal Practice in England.

At a meeting of the Council of the Medical Defence Association, on April 21st, a letter was read from the Secretary of the Royal College of Surgeons of England, in which he stated that the College Charter gave that body no exceptional powers to prosecute unqualified persons for practising surgery, and therefore, the College of Surgeons could not assist the Defence Association in suppressing the illegal practice of surgery.

The Obstetrical Society's Conversazione.

The Obstetrical Society held their annual conversazione at the Royal College of Physicians the evening of May the 10th, when the rooms were crowded by members of all branches of the profession, including most of the leading men. The entertainment of the visitors was most completely provided for. In the first place the band of the Grenadier Guards discoursed a selection of music in the entrance hall, an ample supply of excellent refreshments was supplied, the handsome apartments were adorned by numerous valuable paintings and works of art lent for the occasion, and lastly, but most important, a large collection of both the most ancient and the most modern appliances used in the obstetric art was exhibited, as well as many models, drawings, and preparations illustrating the anatomy and pathology of the subject.

Mr. Hardy and the Medical Officers.

We have reason to believe that if the details of any cases of hardship to individual officers are brought to the notice of Mr. Hardy personally there is every disposition on his part to have them carefully looked into, and, if possible, remedied.

International Congress of Hygiene.

On the 15th of June next an International Exhibition and Congress of Hygiene is to be opened at Brussels. The exhibition is to be divided into ten classes. One of these is to be devoted to Medicine, Surgery, and Pharmacy.

The University of Durham.

The *Students' Journal* observes that at the last graduation ceremony at the University of Durham there were two medical graduates, or rather one graduate in medicine and one in surgery. "It is a question," it says, "whether a university that does so little for the education of the country as is done by the University of Durham should be allowed to exist. A deal of money must be spent in professorships, &c., and the country is scarcely benefited by it. Here is a subject for inquiry and sweeping reform."

A Rare and Valuable Book.

In the library of the Medical Society of London there exists a copy of a work by Servetus, "Christianismi Restitutio—De Trinitate Divina."

Every original copy of this work except one, which was retained by Colladon, one of Servetus's judges, was burned along with the author by the implacable Calvin, for which copy the late Duke of Valiese paid nearly 400 guineas, and it sold at his sale for 3810 livres to the King of France.

The edition, a copy of which is in the library of the Medical Society, is without name of place, printer, or date. It is said to have been printed in London, in the year 1723, by Palmer, in Swan Alley, for Thomas Osborne, bookseller, but before it was completed was seized upon by John Kent, *Messenger of the Press*, and Wm. Squire, *Messenger in Ordinary*, on the 27th May, in the above year, at the instance of Dr. Gibson, Bishop of London, and burnt, a very few copies excepted.

In this book is contained the first account of the circulation af the blood—nearly 80 years before the immortal Harvey published his discovery—(page 143 to page 151).

Dr. Willis suggests that the copy which is now in the National Library of France was the one which belonged to Colladon, the advocate who prosecuted Servetus at the instance of Calvin, and must have been given to Colladon by Calvin to prepare himself for the case, the passages on which Servetus was arraigned being underlined most probably by Calvin.

Phyllocyanin, the blue principle of the iris and the violet, is stated by Sig. G. Pellagri to be a most delicate test for alkaline reactions.

Notice has been given that an examination of candidates for thirteen appointments as surgeon in the Indian Medical Service will be held in London in August, 1876.

The Gold Medal of the Dublin Pathological Society has been awarded to Mr. Beattie, Steevens' Hospital, Dublin, for his essay on "Bursitis."

A dinner is to be given to Sir Joseph Fayrer at St. James's Hall, Piccadilly, on May 24th, by his friends of the Indian Medical Service.

Surgeon-General Sir Joseph Fayrer had the honour of being presented to Her Majesty the Queen on Friday last, on his return from India with H.R.H. the Prince of Wales.

Dr. Chadwick, of Bolton, who has lately died, has left £5000 to the infirmary of the town, and the like sum to the corporation for a public museum. This makes £32,000 he has given to Bolton.

Announcement is made in the *Répertoire de Pharmacie* that Professor Chevallier finding himself compelled to give up the direction of the *Journal de Chimie Médicale* which he has edited for fifty years, these two journals will be combined.

The lectures at the London College of Surgeons will be resumed on Monday, June 5th, by Professor R. Brudenell Carter, F.R.C.S., who will deliver six lectures "On Questions in Ophthalmic Surgery." Mr. Turner, M.B., F.R.S.E., Professor of Anatomy in the University of Edinburgh, will deliver three lectures "On the Comparative Anatomy of the Placenta," in continuation of his course of last year.

The *Manchester Examiner* states that overtures have been made to the corporation of Salford by a wealthy gentleman connected with the borough, for the transfer to the corporation of a suitable site and buildings outside the borough for the purposes of a convalescent hospital. The value of the proposed gift is estimated at £20,000. The *Norfolk Chronicle* also states that the friends of the Norfolk and Norwich Hospital will hear with pleasure that the Lord Lieutenant has promised £5000 towards the extension of the building, provided that £30,000 additional is promised within twelve months' time.

The anti-vivisectionists in Italy have achieved a small victory in having driven Professor Schiff, the distinguished experimental physiologist, from the chair which he occupied at Florence with so much industry and so great advantage to humanity. His departure, says the *Gazetta Medica di Lombarda*, is not only a blow to science, but to common sense and true philanthropy. But the Florentine "Società Bestiofila" will have little cause for rejoicing at its victory, since neither is Prof. Schiff the originator of vivisections, nor will his successor, whoever he may be, be able to do without this now indispensable condition of progress of biological science.

The spiritualists have laid claim to the dignity of martyrdom on the ground that science has refused or omitted to investigate their phenomena, and condemned them unheard. They can no longer complain of being thus ignored, for the Physical Society of St. Petersburgh has taken the subject in hand and gone into a thorough investigation of the statements put forth by the spiritualists and the phenomena which they display. The result of this inquiry is the conclusion to which the Society has given expression, "that those so-called spiritual manifestations proceed from unconscious movements, or from a conscious imposture, and the spiritual doctrine is a superstition."

In connection with the exhibition of scientific instruments at South Kensington, a conference in biology will be held on the 26th and 29th of May, and will relate chiefly to the following subjects:—1. The methods of measurement and registration which are applicable to the vital phenomena of plants, animals, and man; 2. The methods and instruments employed in physiological optics and acoustics; and 3. The modes of preparing the tissues of plants and animals for microscopical examination. Explanations of apparatus and instruments, will be given by the Chairman (Dr. Burdon Sanderson), Drs. Donders, Hering, Marey, Crum-Brown, Michael Foster, M'Kendrick Messrs. Flower, Thiselton Dyer, Liebreich, Pritchard, Mosso, Gaskell, and others.

On Wednesday last the degrees were conferred at the London University. Lord Granville said that there was one point to which he must call the attention of the Senate, and that was as to the possibility, either with or without modification, of giving a fair trial to the experiment of admitting women to medical degrees. It was clear that women were getting more into practice than before, and that more were studying abroad and preparing themselves for such practice. He thought this was a subject which, without anticipating any decision, it would be very difficult for the University not to take at some early period into their very earnest consideration. Mr. Lowe, the member for the University, said he rejoiced to hear the opinion of the Chancellor, that the time had nearly come when the right of women to be admitted to the medical profession could fairly be attended to. He could not help thinking, from the last debate on the subject, that Parliament was entirely of that opinion.

We quoted recently a statement that a noted homœopath in the East End of London, was publicly said to be a member of the Council of the British Medical Association, and that the Medical Defence Association had called the attention of the Council to the circumstance which, we expressed our hope and belief, would be authoritatively denied. We are glad to observe that, at the last meeting of the Council of the Defence Association, a letter was read from the General Secretary of the British Medical Association respecting a medical man who is publishing objectionable handbills on homœopathy in the East End of London, and whose name appears in Churchill's *Medical Directory* as a member of the Council of the British Medical Associtaion, in which he stated that the person referred to *was not a member of the council, and was not in any way connected with the association.*

The Messrs. Churchill must do themselves and their *Directory* justice by expunging from it the name of a person who deliberately deceived them by a false statement.

Correspondence.

PHARMACEUTICAL CHEMISTS AND THE NEW JURIES BILL.

The following letter has been forwarded to the Chief Secretary by direction of the Council of the Pharmaceutical Society of Ireland:—

Pharmaceutical Society of Ireland,
6 Kildare Street, Dublin,
May 5th, 1876.

Sir,—On the 5th of February last I wrote to you by direction of the Council of the Pharmaceutical Society of Ireland,

enclosing a copy of the following resolution unanimously adopted by the Council at its meeting on February 2nd, viz.: —

"Resolved—That the Council request the Chief Secretary for Ireland to exempt Pharmaceutical Chemists in Ireland from service on juries in the new Juries Act, as is the case at present in England."

On the 18th April Mr. J. T. Holmes, a member of the Council, wrote to you drawing your attention to the fact that amongst the list of persons exempt from juries in the Juries Amendment Bill he did not see pharmaceutical chemists mentioned. To this letter he received a reply stating that the request should receive consideration.

I am again directed by the Council to bring the matter under your notice, and to express an earnest hope that you will grant the request conveyed by the resolution.

I have the honour to be, Sir,
Your obedient servant,
HUGH JAMES FENNELL, Registrar,
Pharmaceutical Society of Ireland.

Sir Michael Hicks-Beach, Bart., M.P.,
Chief Secretary for Ireland.

The following reply has been received: —

Irish Office, London,
May 6th, 1876.

Sir,—I am desired by Sir Michael Hicks-Beach to acknowledge the receipt of your letter of the 5th inst., and to state that, as at present advised, he does not see sufficient reason for extending the exemption for service on juries to pharmaceutical chemists. I am to request that you will acquaint the Council of the Pharmaceutical Society in Ireland accordingly.

I remain, Sir, your obedient servant,
MARCUS CAULFIELD.

Hugh J. Fennell.

A meeting of pharmaceutical chemists was held on Monday evening, when it was resolved to request some private member to move in the matter. Mr. Holmes was requested to communicate with Mr. Errington, M.P. The following letter has been forwarded:—

30 Upper Baggot Street, Dublin,
May 13, 1876.

Mr. Errington, M.P.,

Dear Sir,—I have been directed by the members of the Pharmaceutical Society of Ireland to ask you to assist us in having pharmaceutical chemists included among the exemptions from jury service in the Juries Bill at present before Parliament. I enclose copy of correspondence which has taken place on the subject, by which you will see exactly how the matter stands. I could bring strong arguments before you in favour of our view, but consider that the fact that pharmaceutical chemists in England are exempt makes further argument unnecessary. No doubt the Chief Secretary's reason for declining to accede to the request of the Pharmaceutical Council is not to limit unnecessarily the number of intelligent jurors, but as it is not likely that Ireland will support more than one thousand pharmaceutical chemists, that is, one to about five thousand inhabitants, this small addition to the exemptions would scarcely be felt. I shall be greatly obliged if you will do your utmost in the matter.

Your obedient servant,
J. T. HOLMES.

Literature.

CONTRIBUTION A L'ETUDE DES TUMEURS DU TESTICLE. (a)

DR. G. NEPVEU is favourably known to English pathologists for his various communications made to learned societies in Paris concerning infusoria in the blood of erysipelatous patients, and of bacteria in subcutaneous abscesses, &c. The pamphlet before us is one which will add greatly to the reputation of this most able microscopic inquirer and pathologist.

It is composed of nine chapters. In chapter i. the author treats of pearly tumours of the testis, and epithelioma of the testicle; in chapter ii. of encephaloid tumours; in chapter iii. of scirrhus of the testis; in chapter iv. of tubercle; in chapter v. of benign fungus of the testis; in chapter vi. of gummy tumour; in chapter vii. of hæmorrhagic vaginitis; in chapter viii. of myoma; and in chapter ix. of tumours of the scrotum.

Dr. Nepveu is of opinion that pearly tumours of the testis arise from the epithelium of the organ, and that the cysts which accompany them have for their origin the canaliculi. Epithelioma, adenoma, and atheroma have, he thinks, the same origin. Encephaloid of the testicle is for the most part a mixed tumour. The different epitheliums of the seminal parenchyma, the vasular, lymphatic, and testicular epitheliums, are affected at the same time as the connective tissue, the lesion of which is the most important. Most generally the base of these encephaloids is lymphoid sarcoma, which is named by some authors embryoplastic sarcoma, medullary sarcoma, or embryoplastic tumour. They commence on the wall of the tubes themselves.

He gives cases of true scirrhus of the testicle, which has been said by some authors never to occur.

According to Dr. Nepveu, we find tubercles of the testis in three forms—grey granulation, fibrous tubercle, and disseminated tuberculosis. The two first forms may be isolated or united in masses.

The study of diseases of the testis is still rather obscure, and this is easily explained by the composition of the seminal gland and the manifold elements met therein, as well as by the nature of the tumours ususlly found in it, which are of doubtful character in many cases, and about which many disputes have arisen among authors. Most of the nineteen observations recorded in this book are either from the wards of La Pitié Hospital, and were under the care of that eminent surgeon Dr. Verneuil, or were seen in the practice of the late Dr. Demarquay. One of them was under the care of M. Ricord, whose observations on syphilitic testicle are well known.

Pearly tumours of the testicle were first described in 1829 by Cruveilhier, who noticed them in a testicle attacked by alveolar cancer. M. Nepveu emits the hypothesis that these pearls have for origin the tubuli seminiferi. He asserts that these tumours, wherever situate may be arranged under three groups—epithelioma, atheroma, and adenoma of pearly aspect. It is impossible to diagnose their occurrence on the living subject, and they are never generalised. Two years after the ablation of a testicle with this form of tumour the patient was in good health.

In France, pathologists separate epithelioma from cancer, since the first of them clearly is derived from the epithelium. In Germany, on the other hand, another tendency is manifest, and an attempt is made to unite them; the epithelial character of the cancer cells resembles carcinoma of the epithelium. One author, Waldeyer, arrives at the conclusion that cancer arises also from the epithelium. There are, according to this writer, three varieties of cancer—cutaneous cancer, superficial and deep, cancer of the mucous membrane, and glandular cancer. In organs such as the mammary gland, liver, and testicle, the cancer arises from the glandular epithelium, he thinks.

According to Dr. Nepveu, there are no less than six theories as to the origin of cancer. Robin speaks of its free formation in a blastema; Cohnheim asserts that it is formed at the expense of the white blood-globules; Pagentecker, that it is formed by the movable cells of the connective tissue; Virchow, from the fixed elements of the tissues; Waldeyer, from the epithelium already existing; and Langhaus has a mixed theory.

After giving some examples of epithelioma and encephaloid of the testicle, which are beautifully illustrated by carefully drawn plates, Mr. Nepveu adds that the abla-

(a) "Contribution à l'Etude des Tumeurs du Testicule." 2me edition. Par le Dr. G. Nepveu, Chef de Laboratoire de la Pitié. Paris: Delahaye. 1875. Pp. 100, with two plates.

tion of such tumours gives sometimes excellent results. Thus, M. Verneuil cites in his clinical lectures two cases seen in private practice, which he sees from time to time, castration in one of these cases dating eight years back.

Scirrhus of the testicle is rather rare; it is accepted by Curling, but doubted by Rindfleisch, although Cooper and Curling give cases of it. In chapter iii, M. Nepveu gives a clear case of this disease. In the observations there were found under the microscope enormous trabeculæ with hard and resistant connective tissue, extending from the corpus Highmorianum to the tunica vaginalis, and containing in their nets small foci, in which are contained cells of evident polymorphism and well marked.

The difficulties which surround the study of tubercle of the testis are rather numerous. Virchow only considers the grey granulations as tubercles; Rindfleisch has never seen it in the testicle. The grey granulation has been pointed out in the connective tissue, in the epithelium of serous membrane, in the pleura, in the endothelium of the lymphatics, in the epithelium of glands, in that of the follicles of the thyroid gland, and in the sheath of the small vessels. Virchow asserts that proliferation of the connective tissue is the origin of tubercle; Cohnheim asserts that it originates from the white blood-corpuscles or lymphatic elements; Rindfleisch, from the epithelium. Of late years the theory of the origin of tubercle by a kind of lymphatic neoplasm has been received with much favour.

Is nothing tubercle except the grey granulation? Is the fibrous nodosity with cheesy centre tubercle? We find the latter in the brain and testicle. Billroth remarks that tubercles vary essentially with the organs where they arise; those of the epipiloon have a great tendency to become indurated and surrounded by a capsule, whilst those of the lungs early soften; in the kidneys they are localised or disseminated.

Miliary tubercles are rare in the testicle, but Dr. Nepveu has met with them sometimes. Rindfleisch did not find them, and remarks that tuberculosis occupies in the testicle the region where a rich network of lymphatic vessels has been demonstrated to exist, and that the origin of the neoplasm was from the lymphatic endothelium. It therefore seems probable to him that in the testicle, if tuberculosis, in place of presenting itself in the form of granulation, rather puts on the diffuse form, this is due to the fact that the minute phenomena take place within the lymphatics, and are only distinguished from ordinary miliary formation by their more diffuse aspect.

In observation xii. M. Nepveu found in the testis a mass of little atrophic fibromata with cheesy degeneration in the centre, coinciding with a manifest tuberculosis of the kidney. He therefore asserts that side by side with the grey granulation we must place the fibrous tubercles; each of these lesions may exist and form, united in groups, great tubercular masses. There exists also in the testis a disseminated tuberculosis, as in the kidney.

In chapter vi. our author gives us a case of gummy tumour of the testis. He remarks truly that it is rare that we are enabled to study the syphilitic lesions of the testicle, special conditions being required—as when an eminent syphilographer like M. Verneuil makes a mistake and extirpates a syphilitic tumour. Such an error is difficult to avoid, especially when the general characters of the tumours are far from being those of the gummy tumours of the testicle, and when we have in vain tried the touchstone *par excellence* of syphilis, the iodide of potassium.

In observation xvi. the author gives the case of gummy tumour in a man aged 37, who had no clear history of syphilis. The patient was examined with the greatest care by M. Verneuil, who came to the conclusion that the tumour was a sarcocele, without specifying the nature. The tumour had none of the characteristics of syphilitic sarcocele; and, besides, the patient had taken without effect the iodide of potassium for several months. The tumour was gradually enlarging. When the operation was concluded, M. Verneuil incised the mass, and immediately recognised all the characteristics of the venereal testicle—dense, elastic tissues, almost cirrhotic, with yellowish masses diffused and non-united in distinct foci, but circumscribed. The microscopic examination of the tumour, which was of elastic consistence, without foci or softening, but of a yellowish hue, which was peculiar and characteristic, taught nothing further.

The tissue of the tumour was in great part formed of granular and fatty masses, in which it was possible to recognise some fibroid tissue, and some atrophied cellular elements. Around these lesions there were seen embryo cells in great quantity, either in long file along the vessels, or disseminated. Beyond this zone several masses of star-shaped cells were seen, surrounded by connective tissues of variable aspect. No seminiferous tubuli were anywhere visible, and the operation had thus removed an entirely fictitious testicle.

The epididymis and lower part of the cord had disappeared in the mass of the tumour, which was very little vascular. The case was, then, an interstitial orchitis of syphilitic origin in its cheesy state. The diagnosis was at last confirmed. In a few weeks there appeared on the left tibia a syphilitic exostosis. With regard to this point, M. Verneuil observed in his clinical lecture that traumatic lesions give a shake to the whole economy, and reawaken long-forgotten diatheses. Thus, he has often seen, after an operation, a latent syphilitic diathesis suddenly become revealed by exostosis, or lesions of the same order. One of his most distinguished pupils, Dr. Petit, has taken this subject for his thesis, entitled "Traumatic Lesions and their Relation to Syphilis." This is a most interesting and excellent thesis.

Summing up, says M. Nepveu, the characteristic aspect of the testicle on a fresh incision of the organ, the presence of ulterior syphilitic accidents, and the existence of an interstitial orchitis, in the cheesy condition, these are the reasons which compel us to say that this was syphilitic sarcocele. Nevertheless, we may remark that the microscope is of but little aid in such a case as this. There is not in interstitial orchitis of syphilitic character, when arrived at the cheesy stage, any tissue proper to syphilis, and which immediately proclaims its nature.

The cheesy conditions of the testicle are also observed in many circumstances: in pure fibroma, in tubercle, in simple interstitial orchitis, in the most of the tumours of the organ, such as sarcoma and cancer. When once the microscope has demonstrated the absence of special lesions, tubercular granulations, or characteristic signs of cancer or sarcoma, we find ourselves in presence of hyperplasiæ of simple nature, the nature of which can only be made clear by clinical experience, and rarely by the microscope.

M. Nepveu's work is the clearest and most able *résumé* of the subject of diseases of the testicle which has yet appeared, and will doubtless become a standard of reference.

Medical News.

Royal College of Physicians of London.—The following gentlemen were admitted Fellows of the College on Monday last, May 15th:—

Anthony, John, M.D., Birmingham.
Barry, John O'Brien Milner, M.D., Tunbridge Wells.
Bateman, Frederic, M.D., Norwich.
Brodie, George Bernard, M.D., 56 Curzon Street, W.
Brunton, Thomas Lauder, M.D., 23 Somerset Street, W.
Cavafy, John, M.D., 2 Upper Berkeley Street, W.
Hollis, William Ainslie, M.D., Brighton.
Paine, William Henry, M.D., Stroud.
Woodman, W. Bathurst, M.D., 6 Christopher St., E.C.
Yeo, Isaac Burney, M.D., 44 Hertford Street, W.

Vital Statistics.—From the Registrar-General's return we learn that during last week 6,176 births and 8,589 deaths were registered in London, and twenty-two other large towns of the United Kingdom. The mortality from all causes was at the

average rate of 23 deaths annually in every 1000 persons living. The annual death-rate was 25 per 1000 in Edinburgh, 21 in London, 29 in Glasgow, and 26 in Dublin. The annual rates of mortality during the same period in the other large towns were—Norwich 18, Hull 22, Leicester 21, Portsmouth 16, Newcastle-upon-Tyne 21, Birmingham 21, Brighton 16, Leeds 24, Wolverhampton 31, Bradford 29, Sheffield 26, Plymouth 19, Bristol 22, Oldham 29, Manchester 31, Salford 29, Nottingham 22, Sunderland 21, and Liverpool 26. The annual death-rate from the seven principal zymotic diseases averaged 3·4 per 1000 in these towns, and ranged from 0·6 and 0·7 in Norwich and Plymouih, to 6·3 and 6·8 in Portsmouth and Salford. The high zymotic death-rate in Portsmouth was principally due to fever, and that in Salford to small-pox. Fourteen more deaths were referred to small-pox in Manchester and Salford, where 171 fatal cases have been recorded since 1st January last, exclusive of those occurring in the Monsall Hospital, situated without the city of Manchester. In London, the 1,416 deaths included 2 from small-pox, 53 from measles, 48 from scarlet fever, 5 from diphtheri, 75 from whooping-cough, 16 from different forms of fever, and 15 from diarrhœa; thus to the seven principal diseases of the zymotic class 214 deaths were referred, against 247 and 217 in the two preceding weeks. These 214 deaths were 26 below the corrected average number from the same diseases in the corresponding week of the last ten years, and were equal to an annual rate of 3:2 per 1000.

NOTICES TO CORRESPONDENTS.

☞ Correspondents requiring a reply in this column are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

Reading Cases.—Cloth board cases, gilt-lettered, containing 26 strings for holding each volume of the Medical Press and Circular, can now be had at either office of this Journal, price 2s. 6d. The postal regulations not allowing the Journal to be stitched, these cases will be found very useful to keep each weekly number intact, clean, and flat, after it has passed through the post.

Mr. G. B.—We commend our correspondent, who forwards us a little work on "Spiritualism," to Messrs. Maskelyne and Cooke, at the Egyptian Hall in London, where he will find some very marvellous and astounding miracles performed by those clever magicians without the aid of spiritualism or supernatural agency. We can scarcely believe that even the most zealous upholder of the doctrine would not come away convinced against his will and wishes that what before he had faith in was nothing more than "humbug."

Dr. Evans, Reading.—Complaints have reached us from more than one quarter of the annoyance occasioned by a person styling himself Dr. Evans, of Reading, Berkshire, sending a pamphlet headed "A Pure Mind in a Pure Body," through the post to their houses. This individual, whom we have reason to believe has no legal right to dub himself "Dr.," dedicates his pamphlet to "Dr. George Washington Evans, LL.D., F.S.A., M.R.C.S.England," his son, who, strange to relate, resides within smell of the parental food, and whom we trust is a worthy son of a worthy scion. This said pamphlet informs those whom it may concern that Dr. Evans has taken a London house for the convenience of his patients, where he can be consulted on certain days, winding up with an appeal to those who receive the book "to send it to their friends"—not a bad idea of "killing two birds with one stone." We commend the subject to the authorities of the Royal College of Surgeons, and also to the Medical Defence Association. We know for a fact that this *soi-disant* Dr. Evans, of Reading, has been carrying on this same sort of practice for the last twelve or fifteen years.

Mr. J. Needham will bring forward a case of "Cirrhosis of Child's Liver" on Friday next, at the meeting of the Medical Microscopical Society, at 8 p.m.

Legislation for the Intemperate.—We are asked to announce that a mass meeting will be held in Hyde Park on Whit Monday, for the purpose of strengthening the hands of Sir Wilfred Lawson in his endeavour to carry the "Intoxicating Liquors Bill" through Parliament. The moral and material aid of the medical profession will be acceptable.

Messrs. Bircham and Co., Solicitors to the Southwark and Vauxhall Water Company, have sent us another letter on the subject of "The Richmond Water Supply." As, however, it contains nothing which has not been already said, and we have devoted considerable space to the discussion, we are unable to find space for further correspondence.

Tooth-drawing at the Antipodes.—Perhaps some of our friends in the dental profession will thank us for the following clipping from the *Melbourne Medical Record*, as illustrating the ease with which teeth may be drawn with the aid of forceps:—"A Melbourne doctor, who is very fond of giving calomel, asked a patient, who had been taking it in pretty large doses for several days, if his teeth were affected. 'I don't know,' hissed the poor slobbering patient, 'but I have brought all I had in this paper for you to see.'"

Expected Operation, London Hospital, Wednesday, May 17th.—*Osteotomy.*—Mr. Maunder will perform Subcutaneous Section of the Femur below the Trochanter on Wednesday, the 17th May.

The Jacksonian Prize for 1877.—The subject for competition will be "The Disease of the Lymphatics."

A Curious Mistake.—In the *Lincolnshire Chronicle* of Saturday last occurs the following:—"Mr. J. B. Jacobson, son of Dr. Jacobson, of Sleaford, last week passed the preliminary examination at the *Agricultural Hall*, London, as required by the Medical Council of candidates for the medical profession." Readers of this paragraph need not be timorous that our governing body have added the science of producing turnips to the already stiff curriculum, nor need they wander to Islington, as Mr. Jacobson appears to have done, the Apothecaries' Hall is the only Hall whose whereabouts they need trouble themselves to find for their preliminary.

Communications, Enclosures, &c., have been received from—Dr. Carpenter, Croydon. Dr. Delawarre, Paris. Dr. Dalton, New York. Dr. Ogilvie Will, Aberdeen. Dr. Julius Althaus, London. Dr. Handsel Griffiths, Dublin. Mr. Porter, Dublin. Dr. Davis, Newport. Dr. Middleton, Westmeath. Dr. Drysdale, London. Dr. Dickinson, London. Dr. Abrath, Sunderland. Mr. Bremridge, Pharmaceutical Society. Dr. Ashenden, Hastings. The Registrar-General. Mr. Haden, London. Mr. Bircham, London. Dr. Despailles, Contrexville. Mr. Fleming, Chatham. Mr. Brown, Islington. Mr. Browne, Newport. Mr. Crawford, Edinburgh. Dr. Parke, Aghalee. Dr. O'Neill, Dublin. Dr. Whittaker, Broadway. Dr. Thompson, Bray. Dr. Scully, Clonmel. Dr. Symes, Skerries. Dr. Welsh, Ballyshannon. Dr. Barry, Limerick. Dr. Browne, Dungannon. Dr. Morton, Castleblaney. Dr. Whilta, Monaghan. Dr. Stoney, Abbeyleix. Messrs. Graham and Co., Dublin. Dr. Thornley, Newry. Dr. E. Rawson, Carlow. Dr. Langley, London. Dr. Booth, Chesterfield. The President of the Medical Society of London. Dr. Charlton Bastian, London. Dr. Bayes, London, &c., &c.

VACANCIES.

Royal Infirmary, Liverpool.—Medical Superintendent of the Lunatic Asylum. Salary, £2 0, with £50 for wife, as matron, with board and residence. Applications to E. Gibbon, Esq., at the Infirmary.

Keighley Union.—Medical Officer of Health for Sanitary Inspection. Salary, £50 per annum. Applications, endorsed "Medical Officer of Health," to be sent to the Town Clerk's Office, Keighley.

Cancer Hospital, Brompton.—Surgeon. Also an Assistant-Surgeon to out patients. Honorarium. 100 guineas and 50 guineas respectively. (See Advt.)

Ashton-under-Lyne Infirmary.—House-Surgeon. Salary, £80, with board. Testimonials to Mr. Hugh Mason, Ashton-under-Lyne.

Westminster Hospital Medical School.—Demonstrator of Anatomy. Salary, £75. Address the Dean.

Ipswich Lunatic Asylum.—Assistant Medical Officer. Salary, £100, with board, &c. Address the Medical Superintendent.

Bournemouth General Dispensary.—House-Surgeon. Salary, £120. Testimonials to R. T. Hearn, Esq., at the Dispensary.

Brighton Lying-in Institution. House-Surgeon. Salary, £120. Applications to the Chairman of the Committee.

Knighton Union.—Medical Officer for the Leanbister District. Salary £100, with fees extra. Testimonials, &c., to the Clerk to the Guardians.

Newport Union, Achill Dispensary District.—Medical Officer. Salary, £100, with £10 extra as Sanitary Officer. (See Advt.)

APPOINTMENTS.

Bigger, S. F., M.R.C.S.E., M.B., Assistant Resident House-Surgeon to the Liverpool South Dispensary.

Boreham, W. T., L.R.C.P.Ed., M.R.C.S.E., Medical Officer for the Winfrith District of the Wareham Union, and Medical Officer of Health.

Brown, T. Ll., M.R.C.S.E., L.S.A.L., House-Surgeon to the Warneford, Leamington, and South Warwickshire Hospital.

Browne, T. J., A.B., M.B. (Univ. Dub.), L.R.C.S.Ed., L.M., Medical Officer, Public Vaccinator, and Registrar of Births, Deaths, and Marriages to the Dungannon Dispensary District, Dungannon Union.

Burgess, R., L.R.C.P.Ed., L.R.C.S.Ed., Medical Officer, &c., for the Coagh Dispensary District of the Cookstown Union, co. Tyrone, Sanitary Officer for the Coagh Sub-district of the Cookstown Rural Sanitary District, and Medical Attendant to the Royal Irish Constabulary, Coagh.

Clibborn, W., B.A., M.B., Assistant Resident House-Surgeon to the Liverpool North Dispensary.

Cogan, L. F., M.R.C.S., L.R.C.P.Ed., a Medical Officer of Health for the Borough of Northampton.

Cundell, G. R., M.R.C.S.E., Medical Officer for the Kew District of the Richmond Union, Surrey.

Iliffe, W., M.R.C.S.E., L.S.A.L., Medical Officer of Health for the Derby Urban Sanitary District.

McEwen, W., M.D., a Surgeon to the Royal Infirmary, Glasgow.

Madden, A.D., L.R.C.S.I., L.A.H.D., Medical Officer for the District comprising the Parishes of Harlow, Sheering, Matching, and Magdalen-Laver in the Epping Union.

Marriages.

EARDLEY-WILMOT—WHITBY.—On the 3rd inst., at the parish church, Ottery St. Mary, Devonshire, Robert Eardley-Wilmot, M.B., of Petworth, Sussex, to Frances Gwynne, eldest daughter of C. W. Whitby, M.B., of Ottery St. Mary.

MARSH—BEAVAN.—On the 3rd inst., at the parish church of St. Chad, Shrewsbury, Walter Alfred Marsh, M.R.C.S. Eng., of 2 Dante Road, Newington Butts, S.E., to Alice Matilda, fourth daughter of Mr. John Beaman, of Garmstone, Salop.

Deaths.

ARTHUR.—On the 2nd May, at Commercial Road East, John Arthur, L.R.C.P.Ed. & F.R.C.S.E., in his 71st year.

DIGBY.—On the 30th April, at Hunter Street, Brunswick Square, W.C., Edward Digby, M.R.C.S.E., aged 68.

GREEN.—On the 26th April, at Highgate, Kendal, Thomas Green, M.B., M.R.C.S.E., L.S.A., and L.M., in his 55th year.

INMAN.—On the 3rd May, at Clifton, Thomas Inman, M.D., late of Liverpool, aged 56.

MASON.—On the 27th April, at Sunnyside, Ayr, Dr. James Mason, formerly of St. Anne's, Montreal, aged 81.

PATTERSON.—On the 26th April, at Foulmire, Cambridgeshire, Mervyn Patterson, L.S.A.L., aged 74.

RUSSELL.—On the 5th May, at Greenfield, Rathfarnham, Dublin, the residence of her father, Henry Croly, M.D., F.R.C.S.I., after a long and painful illness, Isabel, the beloved wife of J. Russell, 2 Park Road, West Brompton, London.

RUST.—On the 28th April, Henry Rust, M.R.C.S., of Weathersfield, Essex, aged 59.

ST. MARY'S HOSPITAL MEDICAL SCHOOL, Paddington, W.—October, 1876.—Scholarships in Natural Science, Classics, and Mathematics, ranging in value from £120 to £20.—For further particulars apply to the Dean.

A. B. SHEPHERD, M.B., Dean of the School.

GENERAL NURSING INSTITUTE for TRAINED HOSPITAL NURSES.
5 Henrietta Street, Covent Garden, W.C.
A. EBSWORTH, F.R.C.S., Director.

MEDICAL PROFESSION.—WANTED, a Catholic Qualified Medical Practitioner, a good Accoucheur, to carry on an established house in Thurles, the Proprietor being over-worked in another neighbourhood. Will pay a fair salary. Testimonials required. Address M. J. C., 28 Ely Place, Dublin.

THE STEWART INSTITUTION FOR IMBECILES, AND LUNATIC ASYLUM, LUCAN.

PATRON:—H.R.H THE PRINCE OF WALES.

This Institution was founded in 9, and has already attained a large measure of success. It is situated in a healthy locality, and is under the superintendence of a Resident Physician, with trained teachers, who endeavour by the most improved methods to develop the powers, mental and physical, of Imbeciles.

To the pupils who can receive such instruction useful trades are taught. In that of mat making, particularly, excellent progress has been made, and an inspection of the work is invited either at the Institution or at the office

The Institution is the only one of its kind in Ireland, and is mainly supported by voluntary contributions.

Pupils are admitted free by election, or by payment of £40 per annum. A higher rate is payable for separate accommodation.

Contributions to the fund for the erection of the proposed extensive buildings at Palmerston are earnestly solicited.

Each donation of Five Guineas gives the donor a life-vote.

Annual Subscribers are entitled to one vote for each half guinea paid.

An Asylum for Lunatic Patients of the middle classes, under a well-organised administration, also forms part of the establishment.

Full particulars as to the working of both Institutions, terms, &c. can be had at the office,

40 MOLESWORTH STREET, DUBLIN,
W. O'NEILL, Secretary.

J. CROSS & SON
18, HOLBORN HILL,
LONDON, E.C.
ESTABLISHED 1813.
ENGRAVERS, PRINTERS, AND LITHOGRAPHERS.

DISPENSING LABELS.

DISPENSING AND CHEMICAL STOCK LABELS
1s. 8d. per 1000.
DITTO, WITH NAME & ADDRESS
from 2s. per 1000.
LABELS CUT BY MACHINERY.

TASTELESS PILLS.—COX'S PATENT.
Dated and Sealed, April 13, 1854.

Surgeons and Chemists supplied with an excellent Aperient Pill (the formula for which will be forwarded), covered with a thin non-metallic film, rendering each pill perfectly tasteless, at 1s. a gross. Postage free. They present an elegant pearl-like appearance, and may be kept in the mouth several minutes without taste, yet readily dissolving, even in cold water, in an hour. Any formula dispensed and covered, and samples, with a list of pills, from 500 different forms which are kept in stock, will be forwarded free on application.

Twenty years' success, as proved by unsolicited testimonials from Medical men in almost every town and village in the kingdom, has produced imitation likely to bring an useful invention into disrepute.

ARTHUR H. COX and CO., Tasteless Pill Manufacturers, Brighton.

ROYAL MEDICAL BENEVOLENT COLLEGE.—Notice is hereby given that the Annual General Meeting of the Governors of the College will be held at the Office of the College, 37 Soho Square, on Thursday, 25th May, at 3 o'clock precisely. Ten Members of the Council will go out of office on that day, in accordance with the provisions of the Act of Incorporation, and it will be proposed to the Meeting that nine of these gentlemen, viz., H. J. Burford Hancock, Esq., Dr. John Hogg, C. F. J. Lord, Esq., N. Montefiore, Esq., Dr. Julius Pollock, B. W. Powys, Esq., J. Lumsden Propert, Esq., Dr. Stamford Felce, and Erasmus Wilson, Esq., be re-elected for a further period of three years, and that John Birkett, Esq., be elected to fill the vacant seat.

The Meeting will also elect a Treasurer in the place of Henry Hancock, Esq., who resigns.

By order of the Council,
ROBERT FREEMAN, Secretary.
37 Soho Square, London, May, 9th, 1876.

India Office, 3rd May, 1876.

INDIAN MEDICAL SERVICE.—Notice is hereby Given, that an Examination of Candidates for thirteen appointments as Surgeon in Her Majesty's Indian Medical Service will be held in London in August, 1876.

Copies of the Regulations for the Examination, together with information regarding Pay and Retiring Allowances of Indian Medical Officers, may be obtained on application at the Military Department, India Office, London, S.W.

A further notice will be issued when the exact date of examination has been fixed.

T. T. PEARS, Major-General,
Military Secretary.

IRISH CIVIL SERVICE PERMANENT BUILDING SOCIETY.

OFFICES—52, LOWER SACKVILLE STREET, DUBLIN.
PRESIDENT—ALEX. PARKER, Esq., J.P.
(Firm of Ferrier, Pollock, and Co.)
VICE-PRESIDENTS:
C. G. Burke, Esq., Master Court of Common Pleas.
T. F. Brady, Esq., Commissioner of Fisheries

NOTICE.

The present rate of interest allowed on Deposit Receipts is 3½ per cent. per annum.

Depositors have the following guarantees, viz.:—

The entire funds must, under the Act of Parliament, be invested on mortgage of freehold or leasehold property.

The total amount receivable on deposit is limited by the Act to two-thirds of the balance due to the Society on its mortgages.

The Paid-up Capital exceeds £135,000.

Remittances may be made by cheque or bank order, payable to the undersigned.

Prospectuses and every information will be forwarded, post free, on application to

ALFRED H. MERCER, Secretary.

NEWPORT UNION.—ACHILL DISPENSARY DISTRICT.—MEDICAL OFFICER WANTED.—The Committee of Management of the Achill Dispensary District will, on Tuesday, the 23rd day of May, 1876, proceed to Elect a properly qualified Medical Gentleman to discharge the duties of Medical Officer in the Achill portion of said District at a Salary of £100 a year, and £10 a year as Sanitary Officer, as also Registration and Vaccination Fees.

There are four Coast Guard Stations in the District, and one Police Barrack, as also private practice.

Applications accompanied by Diplomas and Testimonials, to be forwarded to the Honorary Secretary, Patrick Sweeney, Esq., Currane, Mulranny, Newport, or to the Vice Chairman, J. Potts Brice, Esq., Achill Sound, Newport, Co. Mayo.

By Order, D. BROWNE,
Board Room, Newport, Clerk of Union.
5th May, 1876.

THE DUBLIN DENTAL DISPENSARY,
MIDDLE ABBEY STREET.

Consulting Physician—THOMAS. P. MASON, Esq., M.B., London, F.R.C.S.I., Physician to Mercer's Hospital.

Consulting Surgeon—EDWARD LEDWICH, Esq., F.R.C.S.I., Surgeon to Mercer's Hospital.

Surgeon Dentist—H. CLIFFORD ESKELL, Esq., L.D.S., R.C.S.E.

Anæsthetist—F. ALCOCK NIXON, Esq., L.R.C.S.I.

Secretary—MR. JAMES GERAGHTY.

&c., &c.

This is the first institution of its kind established in Dublin especially devoted to the gratuitous relief of poor persons suffering from diseases of the teeth. It is conducted on perfectly unsectarian principles, where all absolutely poor persons, independent of their creed, will be entitled to, and can obtain qualified dental advice and assistance gratis.

The Dublin Dental Dispensary is intended to be supported by voluntary subscriptions and donations, the success of the movement being entirely dependent on the liberality of the Public.

It is unnecessary here to dilate on the numerous advantages to be derived from the opening of this Institution, which will rank amongst the most deserving of the Dublin charities. Prospectuses, giving full particulars, can be obtained gratis and post free from the Secretary.

The dispensary is open to the public from 9 to 10 o'clock daily (Sundays excepted).

On every Wednesday morning. Anæsthetics will be administered, when medical men are specially invited to be present.

Donations or Annual Subscriptions (however small) will be appreciated, and gratefully acknowledged by any of the officers of the Institution, or by the Secretary (Mr. James Geraghty), to whom Post-Office Orders may be made payable, and cheques may be crossed to Messrs. Ball and Co., Bankers to the Dublin Dental Dispensary.

The Medical Press & Circular.

THE NATURAL HISTORY OF PULMONARY CONSUMPTION. (a)

By A. B. SHEPHERD, M.A., M.B., F.R.C.P.,

Physician to the Victoria Park Hospital for Diseases of the Chest; Assistant Physician to St. Mary's Hospital; &c.

CHAPTER I

MR. PRESIDENT, FELLOWS, and GENTLEMEN,—There are moments, I suppose, in every young man's life when an idea—to himself seemingly a fresh one—stamps itself upon his mind as true, and therefore to be worked out to its full meaning. Such a time occurred to myself, when, one afternoon, I accompanied into one of his wards at Guy's Hospital the late Dr. Barlow, sometimes Goulstonian Lecturer and Censor of this College. I had been working clinically and microscopically at cases of so-called—more commonly, perhaps, in that day than this—"tubercular phthisis". I remember asking him, with the audacity of a student, not always to be reprehended, what was the difference between this "tubercular phthisis" and fatal cases of acute pneumonia, except in the much slower march of the former, and the absence to a very large extent, in it of the pungent heat of skin always present in the latter. I told him that in both I had found what seemed to me very often to be the same microscopical appearances. His answer—the answer of one who had been a fellow-worker with Addison—was that he recognised their great similarity. The thermometer was then unknown; and neither of us had in our minds cases of acute miliary tuberculosis, but cases only of acute primary lung-affection on the one side, and, on the other, cases of chronic primary lung-disease. It needed but little later reading to learn the existence of a discussion—at that time even by no means new, by no means even yet satisfied—the discussion as to the *rôle* of inflammation in phthisis. In the course of events, I became connected with a hospital where, more than before, I was brought face to face with a disease which already had for me great interest; and also with one which gave me large opportunities to observe and watch to its end the occurrence of general tuberculosis in children; side by side have I worked at these cases of "tubercle" in the child, of what I believe to be the same so-called tubercle in the adult, and those much more common cases of so-called "tubercular infiltration" in the latter; and these, Sir, are the sole grounds of excuse for bringing this well-worn subject ouce more before the College.

Since that day of my first wakening to its importance, attention has been paid tenfold to a subject the literature of which in England had slumbered almost since the time of Morton, till the works of the brilliant writers of France stirred the pens of Carswell and Addison; in France itself had interwined round their central point of work the names of Bayle, Portal, Laennec, Louis, Broussais, and Andral; and in Germany had passed on from these, through the hands of Rokitansky and others, the steady flame of increasing light. And every one of the last ten years has added more and more to that literature, in every tongue, till the united voices of all medicine, to use the words of the Latin poet, (a) "tractim susurrant" of "phthisis" and "tubercle." And yet, withal, it has seemed to me for some time that this question of the minute anatomy of pulmonary consumption—this ever-recurring disputation as to the origin and signification of tubercle and its degenerations, which has been, and still is, looked upon in many quarters not only as the most frequent, but the sole, cause of that pulmonary consumption—has overshadewed almost entirely the clinical history and the clinical symptoms. Tubercle has been worshipped, and the patient has been forgotten. And however much it may have seemed so to my mind before,

(a) Goulstonian Lectures.

(a) Virgil., *Georg.* iv. 260.

the discussion on "tubercle" at one of our learned societies not long ago, would, I think, have opened the eyes of most of us to the utter vagueness and confusion in which the subject is encouraged to lie; to the absence of definition and precision in the use of simple words; to the professedly larger knowledge which has not advanced so very much beyond that of the great Frenchmen I have already mentioned—aye, and of Morton himself.

The word "tubercle" has come to be so loose in its usance, both clinically and pathologically, that the most ordinary thinker is bewildered by the variety of its meaning. To quote a late instance—not that it is by any means an uncommon one—Volkmann (*a*) in a paper written last year on the relation of lupus and tuberculosis, looks upon the former as a "granulation-tumour," and so far to be classed with the latter. From the clinical point of view, he thinks it is not very exceptional to find lupus combined with cheesiness of the lymph-glands, &c., in its neighbourhood; and he is of opinion that "tuberculosis of the lungs"—I leave the term, as he does, undefined, though I have a very strong theory as to what he does mean—is no infrequent occurrence in the members of families afflicted with lupus. It is yet, as Rokitansky put it years ago: "The question of old—What is tubercle?—must at this day be changed into, What is this particular tubercle?" (*b*) To some of us who are teachers the matter is brought yet closer; the student, perplexed by the uncertain use of the selfsame word, cries in vain for some definition of "tubercle" and "tubercular"; begs in vain to see this "tubercle," amid the contrariety of opinion, in its supposed development and degenerations; and in time departs from us with only that glib vagueness for which we, his teachers, are most to blame. Yet, once more, the friends of patients affected with early signs of pulmonary consumption, ask us, "Is it tubercle?" and, with a readier judgment than some of us may have intended, place at once the seal of fatality on a disease which is not by any means absolutely hopeless.

My desire in these lectures would be to make an attempt—however feeble—to bridge over the chasm which at present seems to exist between the pure microscopist and the clinical worker; to weld together, if that were possible, and as is much to be desired, the knowledge of the histologist and that of the bedside worker—the real τέλος, as I take it, of the true physician. And in any attempt of this kind—ambitious and difficult as the task be—it is surely of the highest importance to follow out, as far as possible, the dictum of Morgagni, quoted by Andral, as the motto of his incomparable work: "Nulla est alia pro certo nocendi via, nisi quam plurimas et morborum et dissectionum historias, tùm aliorum, tùm proprias, collectas habere, et inter se comparare." (*c*) After this fashion, however imperfectly, I intend to lay before the College the results, not of much original work on my part, but of the comparison of other men's experience and observations, weighed with such justice as my own small knowledge of bedside work and after-death dissections enables me to have. And as I shall try to be precise in my use of language throughout these lectures, I shall not shrink from defining the exact meaning which attaches itself to certain terms in my own mind. Morton in the very first chapter of his *Phthisiologia* (*d*) has accurately laid down what he intended by the name, the English rendering of which, rather than any Latin equivalent, I have purposely placed in the title of these lectures. "*Phthisis Pulmonaris* est consumptio partium universalis a morbido affectu seu infarctione, tumore, inflammatione et exulceratione Pulmonum primum orta, indeque tussi, dyspnœâ, aliisque ejusmodi symptomatis thoracis ab ipso initio stipata, et cum febre primum lentâ, et hecticâ, dien inflammatoriâ, et tandem putridâ intermittente conjuncta (*op. cit.*, p. 3)." On those words, "primum orta," "ab ipso initio stipata," hang more of the natural history of this disease than may be at first suspected. That definition I accept with but small reservation. Had its terms, thus accurately laid down, been followed by later writers, we could never have had the confusion which even still exists in some minds between cases of undoubted phthisis and cases of as undoubted miliary tuberculosis. I shall show presently, from the histories and examinations given by various writers of a more distant as well as of the present day, that the two clauses of Morton's definition on which I have laid stress cannot in any way fairly be applied to cases which are classed by these authors under pulmonary phthisis.

And thus I am led up to a statement—which it is necessary to make to clear my way—of what I believe pulmonary phthisis never to be. And the points to which I shall address myself to-day are these: Firstly, that the primary "tubercle" to which pulmonary consumption was considered to be due was, according to older writers, and is still, according to some writers of the present day, an interstitial growth: Secondly, that this interstitial, extra-alveolar, growth is not the commencement of ordinary consumption. In my other lectures, I shall hope to show that, with certain exceptions to which I shall draw attention, these particular interstitial growths play but a slight, and that a secondary, part in phthisis; and I shall hold, with authorities equal at least in reputation, if not in number, to those who support the contrary, that the pulmonary consumption of this country consists primarily in intra-alveolar changes.

It is impossible not to be struck, in reading works published since the time of Laennec, with the manner in which men's minds, prejudiced already by what seemed an easy, and certainly a very enticing, explanation of the origin of pulmonary consumption, argued, not from fact to fact, but from theories as to facts to further theory. The φυμάτα ἄπεπτα of Hippocrates and Galen had been recognised as the pathological results of phthisis since the early dawn of medical observation; and the general theory of their development and course in the lungs, down to the very moment almost of Laennec's statement, may, I think, be summed up in the words of one whom I have already quoted, and shall frequently quote again. The writer of the *Phthisiologia* lays down (*op. cit.*, p. 73): "Gradus hujus morbi sunt quæ sequuntur, sc. 1°. Infarctio Pulmonum a sero sanguinis inibi copiosè secreto. 2do. Tumor renitens, præsertim vero in partibus Pulmonum glandulosis, ab eodem sero partes istas nimis distendente, et difficilem exitum habente. Qui tumor videtur mihi esse Tuberculum crudum a Galeno memoratum: Quæ tubercula sive crudos, et glandulosos tumores, sæpe in Phthisicorum cadaveribus deprehendi, cum ceteræ pulmonum partes Apostematibus et exulcerationibus essent obsitæ." In his address to his reader, he had already said: "Quin et tubercula per pulmonum parenchyma hic inde dispersa, quæ serius, vel citius inflammata, atque exulcerata funestam phthisim tandem inducunt, nihil aliud sunt quam glandulosæ tunicæ vesicularum pulmonarium quædam intumescentiæ a sero copiose nimis inibi secreto, ibidemque coagulato efformatæ" (*op. cit.*, third page of preface). Here, at any rate in word, though not in fact, was already a foreshadowing of the lymphoid and perivascular theories of Broussais and of to-day; there can, however, I think, be no doubt that these "tubercula cruda" were the old φυμάτα ἄπεπτα—the latter crude, yellow, infiltrated tubercles of Laennec. And probably to Laennec's theory as to the genetic connection between these infiltrations and the grey miliary nodules, which he described as "nascent tubercle," is due the largest part of the uncertainty of thought, and therefore of language, of to-day.

It is, I think, worth while to consider what Laennec's position really was—a position which very largely explains, as I take it, his strong opposition to the views of Brous-

(*a*) "Lupus und Tuberculose." *Berliner Klinische Wochenschrift*, 1875, No. 30.

(*b*) *Path. Anat. Syd. Soc. Translation*, vol. i. p. 294.

(*c*) *De Sedibus et Causis Morb.*, lib. iv. Proem.

(*d*) *Phthisiologia seu Exercitationes de Phthisi* Tribus Libris comprehensæ. Authore Ricardo Morton, Med. D. —Londini: MDCLXXXIX.

sais in reference to inflammation. To Laennec, the "peculiar form of accidental product"—to quote his own words (*a*)—to which modern anatomists have especially applied the name of tubercle, which aforetime was given indiscriminately to every kind of abnormal tumour or protuberance," was essentially extra-alveolar, extra-bronchial. M.Thaon (*b*) credits Laennec with what he considers to be a praiseworthy silence as to the original seat of "tubercle." But his idea of its seat is to be gathered, not, so far as I can remember, from any direct statement, but from the general description which his work conrains. For instance, Laennec distinctly lays down what he conceives to be the difference between excavations in the lung due to ulcers, and those due to tubercles. He asserts (*op. cit.*, i. 20) that a cavity due to ulceration spreads by corroding the tissue in which it is formed; while tubercular cavities, the result of the spontaneous destruction of an accidental product which has discarded and pushed aside, and not destroyed the pulmonary tissue, have no tendency to grow at the expense of the latter. The original words are strong: "Qui a écarté et refoulé, et non détruit le tissu pulmonaire." (*c*) He proceeds to show how the tubercles, at first miliary, develope into crude tubercles; how, "about this period, the lung-tissue, which had been untouched up to that moment, becomes dense, greyish, and semi-transparent, from an infiltration of tubercular matter in its substance; till, on its complete softening, this tubercular matter makes its way out into one of the bronchi"(p. 21-23). Again, he holds (p. 25), that the bronchi are scarcely ever to be distinguished in the tubercular masses, though the direction in which they open into cavities, however small, shows that they must originally have traversed the tubercular matter; not, like the vessels, pushed aside by it, but enveloped by it, and destroyed by compression. These views had been, also, the views of Bayle, in his comparison of tubercular with ulcerous phthisis: he held that, in the former, the lung-tissue was simply compressed, not destroyed by the tubercles. In addition to these tubercles, and a form of infiltrated tubercles (cf. esp. *op. cit.*, ii. 13), Laennec had noted tuberculous masses, not round like ordinary crude tubercles, but irregular and angular, paler, duller, and less distinctly marked off from the lung-tissue (p. 30) than the ordinary ones; these masses he calls tuberculer infiltration, and allows that he has found them by themselves in lungs affected with pneumonia. So far this third kind was evidently due to lobular pneumonias—a fact borne out even by the pathology of our day.

But Laennec, misled even with his eyes open—for he confesses his surprise (*op., cit.*, 2nd edition, 1826, tome i. 538) (*d*) at finding only crude yellow tubercles in cases which he states had presented, during life, all the signs of phthisis—misled, further, by the apparition, side by side in some cases, of certain pathological results which he himself (*op. cit.*, 2nd ed., i. 553) had distinguished, only less accurately than some of us to-day are able to distinguish them, as extra-alveolar and intra-alveolar; and misled, also, as I believe, by confounding the "miliary granulations" of Bayle with the former, the extra-alveolar product, came to that conclusion, which, after him, took fast hold upon the minds of men; and, seeing in the yellow infiltration only the degeneration of the primary nodule, laid the foundation for that mass of generalities which the words "tubercle" and "tubercular" call up. This argument of causation, founded on coincidence of place, led at once to the result of imperfect observation. Bayle (*e*) had noticed, in what he called his "tubercular miliary granulations," a small opaque point in the centre, black or white. Laennec (*op. cit.*, 2nd ed., i. p. 538), in remarking on this in a footnote, claims it at once as evidently the sign of their commencing softening. Andral, (*a*) commenting on Laennec, holds that this central point is the lumen of a bronchus; and here, at last, we come upon an experimental proof which, thirty years afterwards, Virchow, in his *Krankhaften Geschwülste*, following in the wake of Carswell, who had pictured it in 1838, and Addison, who had drawn it even more accurately in 1845, is late to recognise.

Well, indeed, may Dr. Wilson Fox (*b*) say, referring to two distinct views as to this so-called "tubercle," "if tubercle be only the grey granulation, its demonstrable part in the destruction of the lung-tissue is small; if tubercle be a diffused growth passing into or causing caseous change, its part in the production of phthisis is large." And this very alternative impressed me at the time I mentioned my difficulty to my teacher, Dr. Barlow, with the importance of distinguishing between extra-alveolar and intra-alveolar products—a distinction like that made by Buhl into "superficial" and "parenchymatous." For some time I have held and taught that there is no developmental connection between these grey miliary extra-alveolar nodules and the intra-alveolar and intra-bronchial changes which are the commonest results found in the pulmonary phthisis of this country, in the sense that the former are a first stage of the latter—that the two changes are dependent the one on the other I do not deny; to that point I shall return presently; I have held and taught that these grey miliary extra-alveolar nodules never undergo the cheesy change; that the most ordinary form of consumption in this country, as Addison years ago pointed out, consists in slow degenerative changes, which commence in the epithelial lining of the bronchi and alveoli. I should not, perhaps have been so bold in stating these views, which, though already accepted, at least in part, by some, will naturally meet with opposition, had it not been for the publication of the second part of Professor Klein's book on the "Lymphatic System," which to some extent supports me in holding them. As the results of his work must carry more authority than my humble efforts in the same direction, I make no apology for quoting from his book the points in which we both agree. I must refer for the moment to his statement of the results found by himself in the lungs of guinea-pigs in cases of artificial tuberculosis, in elucidating the pathology of which affection writers in this country have borne a very large part. Dr. Klein says (*op. cit.*, p. 53): "The granulations of a lung, which is so far advanced in the process of artificial tuberculosis that the bronchial glands have undergone already necrotic changes, may be distinguished into three kinds: (A) nodules of a more or less well defined outline, being in connection with the wall of a bronchiole; (B) cord-like structures; and (C) nodular structures of a conical or irregular shape." He shows further on that the cord-like structures are due to perivascular cords in connection with the minor branches of the pulmonary artery, or of the pulmonary vein, most probably of the former (pp. 55, &c.); and that the third form of granulations, the nodular structures, owe their origin, as Dr. Burdon Sanderson had already stated, to catarrhal pneumonia. And he asserts (*op. cit.*, p. 53) that "all these three kinds of granulations are of the peculiarly semi-transparent aspect; only the third kind undergoes a cheesy transformation, marked as an opacity in the centre." The argument drawn from these statements in confirmation of my own work was the more strengthened when I came to read a little later on (*op. cit.*, p. 60) that not only are there "cases of artificial tuberculosis in guinea-pigs . . . whose lungs contained miliary granulations, due *only and exclusively* to perivascular cords of adenoid tissue;" but that the professor had "seen a case of 'natural' tuberculosis in a guinea-pig, where the spleen and the liver, and likewise the lungs, but not to such an extent as the former organs, were penetrated by numerous very minute miliary granulations. The mesenteric glands were distinctly, the liver, spleen, and bronchial glands (*c*) only slightly, en-

larged. In the lung the "miliary granulations were found to be due *entirely* to the presence of perivascular adenoid cords;" that is to say—and I am no longer quoting Professor Klein—to the presence of structures of which probably Rokitansky (*op. cit.*, i. 326) spoke with his usual correctness: "This tubercle is subject to no metamorphosis." So far as *post-mortem* facts go to show it, Rokitansky's sentence apparenrly applies to other products, which, as it seems to me, are quite as secondary as these lymphatic, perivascular productions, but seem, if I may be allowed the term, to have had no time to undergo this change. I had hoped at one time to prove, at any rate to my own satisfaction, as others (Deichler, Colberg, Rindfleisch) had professed to demonstrate, that the miliary nodules found in acute tuberculosis, whether in children or adults, were due to perivascular nodules, or at least to proliferation of the capillary nuclei; the unique guinea-pig of Dr. Klein was the type I had hunted for. What I had found, at any rate in the acute tuberculosis of children, was certainly perivascular growth, accompanied generally by slight catarrhal, vesicular products and lobular collapse. And I had noticed, as any man may notice, that especially at the two ends of life—in the general tuberculosis of childhood, and the bronchitic and emphysematous phthisis of advancing age—there were to be found, not only the true perivascular nodules, not always easy to be defined, but products, often themselves alone—products to all naked-eye appearance resembling the "tubercle" of authors—the "grey granulations" of Bayle, which Andral (*op. cit.*, vol. iv., p. 10) recognises, and rightly, as the results of "vesicular pneumonia," and Buhl describes as "lobular foci of desquamative pneumonia." Thus far the results found by myself in these cases differ but slightly from the facts stated by Dr. Klein.

ON THE RIGHT OF THE STATE TO OBTAIN EARLY INFORMATION OF THE APPEARANCE OF EPIDEMIC OR INFECTIOUS DISEASE IN A GIVEN DISTRICT—OUGHT THE MEDICAL ATTENDANT TO BE THE INFORMER?

By Alfred Carpenter, M.D. Lond., M.B., &c.

Probably, in the case of a wilful and atrocious murder, or in the case of wilful injury inflicted upon some unoffending and helpless person, the medical man would decline to be the confidant of the wrong-doer. Even then if the information came to him in the practice of his profession, it would not be *contra bonos mores* to be passive in the matter, just as a barrister who, whilst defending the same man before the court, and who had become aware of his client's guilt, would not be called upon to publish it and thus ruin his client's chance of escape. There would, however, be this difference in the case in point—the medical man would not be allowed to plead privilege in the witness-box, whilst the barrister's plea would be immediately accorded. The medical attendant upon a case of scarlatina should be in a similar position to the medical man in the former case—not called upon to disclose the fact unless he is actually interrogated by some one who has a right to demand the information. We could scarcely put the medical officer of health in the place of the judge and give him a judicial authority over his fellow-practitioners. But still, in the event of such information being demanded in a given case and false information afforded, it would, if my conclusions are adopted, be only right that the private practitioner should be subject to a penalty for so doing.

I think it, however, imprudent to place restrictions upon the confidence which should exist between doctor and patient. The Legislature has very properly declined to place the duty of giving information to the registrar of births and deaths as to the actual fact of a birth or a death upon the medical attendant. A medical man is bound to afford informaiton as to the cause of death in a given case, because he alone is able to certify upon that point, but the fact of the death itself has to be communicated to the registrar by some other person. To make it incumbent upon the medical man alone to give the information was felt at the time the Act was passed as likely to lead to evils worse than those for the correction of which the Registration Act was passed, and as it became necessary to place the duty somewhere, it was not necessary to include in the enactment two classes of persons whilst one class was sufficient. It would not conduce to perfect knowledge to enact a law which should compel medical men to give information to medical officers of health. Another class of persons would have to be included in the Act, and as that other class would be cognisant of every case known to the medical attendant, it is not necessary for perfect knowledge to make both contribute the information.

It is certainly important that medical officers of health should have the earliest possible information as to the appearance of infectious disease in their district, and that early measures should in all cases be taken by the local sanitary authority for its localization and for preventing its spread, and for its eventual destruction.

This information is at present not forthcoming. The domestic and the social habits of the people are in opposition to the promulgation of the required information. The privacy of the family circle is at present so sacred that the medical officer of health has no correct and certain means of getting at the truth. Yet, just as in the case of a birth or a death, there is always some one besides the medical attendant who becomes cognisant of the fact almost as soon as, and often long before, the medical man, and who stands in the position of parent or guardian, or who is responsible to the patient himself for the correct governance of the household during the illness of the head of the establisnment; there is always some one responsible for the sick person's safe keeping, and that person should be obliged to afford the requisite information to the medical officer of health. It is recognised on all hands that the registrar of births and deaths is entitled to demand the information as to a birth or a death from a particular class of persons, and there can be no reasonable objections made to the same class of persons being obliged to give information to the medical officer of health as to the occasion of a case of infectious disease in their establishment as soon as it comes to their knowledge.

Indeed, the law is already in force as to disease of a similar character among cattle. The owner is obliged to give immediate notice to the inspector of his district in the event of infectious disease appearing on a particular farm, and the inspector at once visits the place and gives his instructions. It is no argument against the law that as far as cattle diseases are concerned it is useless towards prevention, because the laws which regulate the spread of infectious diseases among cattle are all but totally disregarded by the farmer, notwithstanding the instructions given by the inspector. But the fact of the law remains, and there is no reason whatever why the rule, which has been made absolute in the case of cattle, should not have a similar effect as regards human beings.

Any medical man holding a public appointment of any kind would assuredly find it to his interest to give the requisite information to the medical officer of health of cases which he met with in the performance of his duty, and no sacred tie would in such cases be interfered with and no possible injury could arise; but these cases are not the most dangerous. Neither the privacy of the family circle nor the privileges of a profession ought to be a bar to the enactment of benificial laws, if there was no other way of reaching the evil; the enactment making it compulsory upon the parent or guardian or the occupier of the premises in question to give the requisite information would meet the case and be sufficient for the purpose, whilst the fact that the medical attendant would be bound, if interrogated by a proper authority, to answer correctly, would prevent the chance of frequent attempts being made to keep medical officers of health in the dark

as to the actual presence of particular diseases in given spots, and be ample for the purpose.

A question is sometimes most broadly put as to why a medical man, being a public servant, should not be bound to give the required information? It is said that the medical man is bound to attend upon the public when called upon, and that he ought, therefore, to be called upon to give information which may protect the public from the danger which infectious diseases produce to the community at large.

The argument, however, is not sound, for the medical man is not a public servant, and cannot be called upon to attend upon a given case unless he sees fit to do so. He is no more called upon by law to visit a sick person than a lawyer is called upon to defend a blackguard before a bench of magistrates, whether he will or no; or a baker to let a beggar have bread without paying for it; or a butcher to let a poor person have the best meat in his shop when he knows that the person in question cannot pay for it.

The public servant, such as is the union medical officer, or the surgeon to a dispensary or a public hospital, whilst performing his public duties, is in a different position, and might be called upon to give the requisite information without loss of dignity, and without betraying the privacy of the family circle, or breaking the tie which ought to exist between doctor and patient, but the public servants are not equal to the occasion.

There is a class of cases in which it is rightly insisted on that information must be afforded at once, viz., in the invasion of the country by a fresh outbreak of cholera or plague; in such case it must be the duty of the medical attendant to give such information at once to the medical officer of health, because in such cases the medical man is certain to be the first to get the knowledge of the fact itself. It could scarcely happen that any medical man or any family would decline to give the medical officer of health the required information under such circumstauces. This duty is rightly demanded at our outports. The small amount of possible private wrong cannot be allowed to stand in the way of a great public benefit.

The Local Government Board, in the General Order, November 11th, 1872, considered it desirable that the guardians should instruct their clerk to copy from the district medical officer's report-book the new cases which are reported at each meeting of the guardians, and forward the same promptly and regularly to the medical officer of health within the union.

"It is very important (says the Order) that this information should reach the medical officer of health without delay, and the Board trust that arrangements will be made for the regular transmission of the copies referred to as early as practicable after each meeting. The board also recommend that the guardians should request the Poor-law medical officer to give the medical officer of health or inspectors of nuisances acting within their respective districts the earliest possible information of *dangerous cases* of infectious disease under their charge."

These orders are comparatively useless for the purpose; they only recommend that clerks to boards of guardians should do that which it is notorious that clerks do not do. It only recommends that cases of dangerous disease should be reported to the medical officer of health, whilst it is absolutely necessary *that all cases* should be so reported, whether dangerous or otherwise. However, whilst the Local Government Board is not in earnest in affording early information for its own officers, it is scarcely to be expected that the general public, or even boards of guardians themselves, will act more energetically.

Whether Parliament will force on the Local Government officials more work than the heads of that department think to be required in the case remains to be seen; it is certain that clerks to local boards and boards of guardians will not do additional work without additional pay, and until the country is more bountiful, or, indeed, more just, towards its sanitary staff than is the state at present, I much doubt whether legislative enactment, even in the direction indicated, will bring satisfactory results.

The "love of his subject" enables the medical officer of health "par excellence" to triumph over many obstacles; he does so from real love of his work; but the majority of men only follow a particular profession as a means of livelihood, and it is not to be expected that they will continue to perform gratuitous work for the benefit of the public alone, and with the natural result to themselves of public odium and ill-merited abuse. Any legislative action, therefore, which provides extra work for Local Government officials must also provide for extra pay; if information of a special kind is also expected from private individuals of any profession those persons ought to be paid for it. Let it be made incumbent upon the parent or guardian or the head of an establishment to give immediate notice to the medical officer of health of the advent of infectious disease in a given house. The medical officer of health should also have power given him to apply to the private medical attendant in a given case for such information as he may really require after the knowledge of that case has reached him. In such case the medical attendant furnishing a report should be entitled to a fee for it, and it should be obligatory upon the reporter to make a true answer to his interrogator.

A regulation of this kind would provide for the the immediate discovery of all infectious diseases, and thus would place upon the medical officer of health the responsibility of advising measures for preventing its further extension, and for taking such measures as he may deem requisite for the safety of the commonwealth, whilst the ordinary medical attendant would restrict his duty to the case of his patient and his patient's friends alone, and save him from the evil consequences which would follow if he were obliged to be a common informer.

TWO NEW MEDICINES: SALICYLIC ACID AND NITRITE OF AMYL.

Translated from *l'Union Médicale*, by FRANCIS M. LUTHER, M.D., Cappoquin.

AN antiseptic and a calmative, two agents which may be destined to render great services in therapeutics, in which we have so often to battle with contagion, and to soothe morbid irritability.

Salicylic acid appears to be, in fact, an excellent type of an antiseptic agent. In its pure form it is a white powder, little soluble in water, soluble in alcohol and heated glycerine. It is the result of various distillations of phénol.

From Muller's comparison of this agent with carbolic acid, it appears that, contrary to the latter, its behaviour towards mucous membranes is so favourable, that it is perfectly tolerated by the stomach and digestive organs. Moreover, it has no odour, and its taste is insipid, rather sweetish.

It is easily absorbed, and two hours after its ingestion Kolbe has been able to demonstrate its presence in the urine by means of perchloride of iron, which colours it deep violet. It is then evidently eliminated by the kidneys, and probably mainly by them.

Now at every point of its passage through the economy this agent plays its antiseptic *rôle*. Neubauer has shown that it is an antiferment, in experimenting with it upon must, mould, &c., and he believes it is destined to be turned to account in the preservation of articles of food and drink. W. Knop has proved that it can even arrest nutrition in the roots of maize and germination in seeds. These facts induced its antiseptic efficacy to be tested as a dressing for wounds. Thiersch has applied it in this manner, and has frequently substituted it for carbolic acid in the dressings practised after Lister's method. Its effect as a disinfectant has always been most satisfactory, in all cases at least in which the state of the wound did not demand a stimulating topical application. Wagner

also remarks that salicylic acid is insufficient for the dressing of venereal ulcers, which require more powerful modifying agents, often even cauterising ones.

I do not know what to think of the use which Wagner has made of it in eczema of the face, but he has found it serviceable in this case too.

The antiseptic power of salicylic acid appears to be exerted in the *primæ viæ*, and even all along the gastro-intestinal tube. That is why Wagner has recommended it in all affections of this apparatus in which there is a tendency to abnormal or excessive fermentation. Stepsanides especially has recognised its efficacy in chronic diarrhœa in general, and dysentery in particular.

With still more reason should it be useful in septic affections of the mucous membranes of the upper portion of the tube; accordingly Wagner has experienced its efficacy as a topical remedy for diphtheria. Frontheim has administered it with apparent advantage as a prophylactic.

From its power of checking fermentation in the contents of the intestinal canal, its exhibition appears to be especially indicated in typhoid fever. Fürbringer, who tried it with this intention, experienced the beneficial effect of its antiseptic action. The modification that the febrile heat seemed to undergo under its influence made him think that it had also some antipyretic influence. Bult came after him, and he attributed to salicylic acid this latter effect. In our present state of knowledge upon this subject its antiseptic properties cannot be doubted. The experiments of Fürbringer have proved that these effects are produced not only in the *primæ viæ*, but even in the blood itself. Thus by injecting salicylic acid directly into the circulation of rabbits whom he had inoculated with pyæmia and putrid infection of the blood, he enabled them to resist the poison, and even get well, thanks to the intervention of this agent, as was proved by several comparative experiments in which salicylic acid was not given, and the infected animals succumbed.

But if it has been clearly demonstrated that the antiseptic action of this medicament extends even to the blood, it is likewise probable that the antipyretic effect or lowering of the febrile heat is rather a secondary than a primary action, and the direct consequence of the destruction of the pyrogenic germs.

This action as an antiferment extends farther. I have said that salicylic acid is eliminated by the urine; now its presence in this product of excretion suffices to arrest the ammoniacal fermentation of the urine (Furbringer), and it becomes on that account an excellent remedy for catarrh of the bladder. Crede gave it also with advantage in uterine catarrh; but in that case it is its topical effect that is wanting; and it is employed in irrigations and injections in puerperal and post-puerperal cases. It is more difficult to explain its efficacy in diabetes; and still Muller and Erbstein succeeded in attaining good results from its use. Must one suppose this due to its power of checkIng fermentation? (*a*)

Salicylic acid is given in doses varying from 2 to 4 grains up to 15 grains and more. Kolbe took, five days running, 20 grains without experiencing any inconvenience. It may be given in solution (it is but slightly soluble), or in powder, by itself or mixed with powdered starch. For dressings it is applied with wadding, like carbolic acid.

Nitrite of amyl, discevered by M. Balard in 1844, is a yellow-greenish, very volatile liquid, with a fruity perfume, obtained by the reaction of nitric acid upon amylic alcohol.

Among the questions that the physiological action of this body raises, that of ascertaining if it is a poison acting on the muscles (Brunton), or on the blood (Gamgee), is not the least important. Now, if the facts of paralysis proved by experiment incline one to see in it an agent that paralyses the muscles or the motor extremities of the nerves, it is also sure that it decomposes hæmaglobuline, as Hope Seyler has succeeded in showing by spectral analysis. One may suppose that such is its essential action, and that it is only secondarily a paralyso-motor.

The effects that it produces are: First, an acceleration of the pulsations of the heart, with dilatation of the capillaries, particularly of the head and neck. Secondly, greater frequency of respiration also. Thirdly, the temperature is lowered; as regards the nervous system there is a cerebral stupefaction. The eye sees a yellow spot according to Pick and Crichton Browne, it has an influence upon the centre of motion of the mouth, and this influence is betrayed by yawns or attempts at this sort of instinctive movement. Under this same influence the urine augments and becomes strongly diabetic.

Stillé, who has classified these data in his "Treatise on Therapeutics," relates that nitrite of amyl has been employed with success against spasmodic maladies. It has been given in angina pectoris (Anstie, Brunton), in spasmodic asthma, (T. Jones), and even in cardiac asthma (?), in tetanus, trismus, and also in syncope (Hunt) (?), and in melancholy (Hosterman).

More extended and more numerous experiments have been collated regarding its effects in epilepsy, and especially the *petit mal*. Bourneville, who has employed it with this aim at Salpétrière, in Charcot's wards, in imitation of Crichton Browne, Pick, and Stecketec, considered that its action was transient and its exhibitions difficult. Perhaps it may be more effective in the treatment of puerperal convulsions (Jenks), and in migraine. Mauzi has given it with success in facial neuralgia, and Fuckel in gastralgia. Lastly, it is a good antidote to strychnine.

Bourneville, alluding to the modes of exhibiting it, remarks that its administration by the stomach is a faulty method; Amez-broz has found the hypodermic injection uncertain. The simplest mode to employ the nitrite of amyl is by inhalation; five drops on a handkerchief is the dose for an adult (Stillé). It is evidently an agent requiring delicate handling. What is chiefly important is to watch the state of the heart during the administration of the drug. Stillé, however, appears to consider of less importance the dangers that it might bring upon the central organ of the circulation than its effect upon the peripheric circulation, should the capillaries be atheromatous or diseased.

In *résumé*, if the employment of salicylic acid as an antiseptic appears simple, easy, and efficacious, it is not by any means so with the nitrite of amyl, which, though doubtless efficacious as a stupefying agent, does not appear to be yet sufficiently withdrawn from the domain of experiment to be classed amongst practical remedies. New essays may soon enable us to draw more favourable conclusions.

(*a*) M. Bouchardat's last theory is worth quoting: "The gastric juice of diabetics, instead of containing only *gasterase*, which, aided by a weak acid, dissolves flesh and albuminous matters, secretes also *diastase*, dissolving amylaceous substances. Let us suppress or considerably diminish for a time the use of amylaceous food. The nature of the fermentible substance being changed, the ferment itself will become modified by degrees, and will insensibly resume the properties which characterise it in the physiological state, that of dissolving fibrinous and albuminous matters without acting on the amylaceous ones."—*Translator.*

Transactions of Societies.

MEDICAL SOCIETY OF THE IRISH COLLEGE OF PHYSICIANS.

The sixth meeting of the Session of this Society took plase on Wednesday, April 12th, 1876, Dr. Gordon, President of the College of Physicians, in the chair.

After the transaction of some formal business, the adjourned discussion on Dr. Hayden's paper on Biliary Colic took place

Dr. Hayden having given a brief *résumé* of the points touched upon in his paper, an abstract of which has already appeared in these columns,

Dr. Grimshaw said he had not very much to say with regard to Dr. Hayden's paper. The fact was that the paper was so full and extensive, the cases given were so well detailed,

and the theories and points treated of in the paper so ably dealt with, that there was scarcely any room left for discussion. He (Dr. Grimshaw) had an opportunity since he heard the paper read of seeing a case which was one of those that had often escaped notice on other occasions, and which had been, he was aware, diagnosed as gastralgia. He had seen the lady on two other occasions suffering from pain, which he now believed to have been owing to the condition which she laboured under when last he saw her. On the last occasion there was no doubt that she was suffering from biliary calculus —though he did not get the calculus ; but he could assure the meeting that Dr. Hayden's remarks on the subject threw a great deal of light on the case, and helped him (Dr. Grimshaw) in his diagnosis. He thought the Society should be indebted to Dr. Hayden for bringing forward a paper of the description that he had read—a paper in which a group of cases had been brought forward, when they had so often to form conclusions from one or two cases.

Dr. HENRY KENNEDY said that one of the exact symptoms of gall-stone might be and had been produced by hydatids and not biliary colic at all. In another case that he had to do with when he was doing duty at the South Dublin Union Workhouse, a robust girl 25 years of age was suddenly attacked with pain at the right side of the stomach. The pain was wonderfully localised. Suddenly vomiting set in, and he was conscious of a tumour developing itself exactly over the liver. The symptoms went on, and did not yield to treatment, and the girl died in 36 or 40 hours afterwards. He felt the tumour during life, and subsequently found that a very ragged biliary calculus had got so far through the duct that it led to peritonitis. The calculus was excessively rough. With regard to the diagnosis, he had never found it as simple as a good many supposed it to be. He had seen a considerable number of cases, but he could not say whether they were biliary calculi or not. They had most of the symptoms, but there was no evidence, as Dr. Hayden had said, of their having passed away. In many cases biliary calculi did not come away. It was merely when calculi got into the ducts and stretched them that great suffering was given rise to. The treatment might be divided into two parts, during the attack, and between the attacks. One of the famous men of the last century—Sir Walter Scott—was a terrible sufferer in the latter part of his life from the disease, and on account of the individual in whom it occurred, the case attracted considerable notice. He was seen by a number of surgeons, and they were all in doubt as to the exact nature of the disease. Well, in that case an army surgeon suggested the use of calomel. He (Dr. Kennedy) was not sure whether Dr. Hayden alluded to that medicine, for he believed it could be made of very great use indeed. He had found a single dose of it have quite a specific effect. He thought that by calomel or blue pill a great deal could be done. The treatment which had been used in the intermediate stage had been ether with turpentine, given with the view of dissolving the stone, and still later an attempt had been made with chloroform. An American physician had proved that chloroform given in such doses as the stomach would bear had proved very useful.

The PRESIDENT said he would take the opportunity of adding to the number of cases enumerated by Dr. Hayden as those for which biliary calculus might be mistaken, and would add cholera, from the fact that he had a perfect recollection of having some time ago been called to see a lady, and he was told she was suffering from a sudden attack of cholera, and he had no doubt after examining her that what she was suffering from was biliary calculus. He did not know whether Dr. Hayden in his paper made mention in any of his cases of the administration of chloroform. Dr. Kennedy had spoken of its administration internally, but not by inhalation. The case he (the President) had mentioned was characterised by marked intermissions, and the moment after an intermission there was intense pain. There was the collapse and a return of the agonising pain, and during the intervals of pain he administered chloroform, giving it pretty freely and at length with perfect success. He supposed that the effect produced was, while under the influence of chloroform, the spasm subsided and at length the calculus passed through. He administered it four different times at short intervals, and as he had before observed, it was eventually most successful. He adopted that method of treatment in consequence of a case that Sir Dominic Corrigan told him he had had a few nights before—that Sir Dominic had been called to see a gentleman suffering from intense biliary colic, agonising pain, vomiting, and then collapse. By the administration of chloroform, the case was completely relieved.

Dr. HAYDEN did not consider that any question had arisen in the course of the discussion to which it was necessary for him to reply, and he had no further observations to make.

Papers were then read by Dr. Grimshaw, "On an Outbreak of Small-pox," and by Dr. Churchill (for Dr. King Kerr, by permission of the Council), entitled, "Notes on some Epidemics in the district of Coagh, Co. Tyrone," upon which discussion took place.

The Society then adjourned.

DUBLIN OBSTETRICAL SOCIETY.

SURGEON-MAJOR JOHNSTON read an interesting paper upon a case of

INTESTINAL OBSTRUCTION,

in which he made an exploratory incision into the abdomen and opened the cæcum. The woman recovered, and after eight months regained the natural use of the bowels. The salient points of the case are that the woman was delivered of her second child in June last year. During the latter half of that pregnancy she suffered from most obstinate constipation, and never had the free use of her bowels after her confinement, even although she took strong purgative medicines. In August and the beginning of September she ate large quantities of damsons, and swallowed the stones and skins. These damson stones appear to have become imbedded in the clayey fæces accumulated in the colon, and to have caused complete obstruction. She was under Dr. Johnston's care for three weeks before the operation was performed, but enemata, opium, belladonna, galvanism, &c., failed to relieve the bowels. On the 13th of October the distension was very great and her sufferings severe. Drs. Banks and Kidd were asked in consultation, and as they also failed to pass the long tube any distance, the latter suggested that the lower bowel should be explored by hand. This was done under chloroform. Dr. Kidd passed his hand through the anus into the rectum and up through the sigmoid flexure into the descending colon. Having met with no obstacle he passed the long tube beyond his hand, and a large quantity of water was then injected towards the transverse colon. No feculent matter came away. No tumour or accumulation of solid fæces could be detected whilst she was under chloroform. When admitted into the Dublin Hospital for Soldiers' Wives, on the 25th September, she retched frequently, and suffered from constant pain and tenderness on the right of the umbilicus, and from intermittent pain a little on the left of it. The fixed pain soon subsided under treatment, and never returned, but the intermittent spasmodic pains became most intense towards the middle of October, and on the 17th were so agonising and incontrollable that her life was considered to be in imminent danger. It seemed impossible she could live many hours. All hope of a natural evacuation taking place was evidently gone, and it was considered a duty to give her the only chance of life.

There being still a doubt as to the seat of obstruction, it was decided to make an anterior exploratory incision. She was therefore placed under chloroform, and an incision, about six inches long, was made from the umbilicus to within an inch and a-half of the pubis. The small intestines protruded and were found to be free from obstruction ; the cæcum and ascending colon were however greatly distended with semi-fluid fæces, and as it now appeared that the obstruction was in the transverse colon, which could not be reached unless the incision was extended upwards, the cæcum was opened and stitched to the lower part of the opening in the abdominal wall. In doing this much difficulty was experienced in preventing the overflowing of the putrescent fæces with the peritoneum, but this danger was apparently obviated, and free vent was then given to the intestinal contents which poured out in great quantities for several days.

About the 12th day the sutures, which were of strong silk, were removed, and the union of the bowel to the abdominal wall was found to be satisfactory. She sat up for five hours on the 21st day after the operation, and her subsequent convalescence was almost uninterrupted. A few days after the operation several damson and raisin stones and skins and vegetable marrow seeds were seen in the discharged matters, and numbers of damson stones were subsequently washed out

of the colon by the enemata which were used in trying to restore the communication with the natural outlet.

Up to the 1st, her urine had to be drawn off very frequently, but on that day and afterwards she passed it naturally.

On the 29th of April of this year she discharged flatus per anum and on the 1st of May she had a hard stool. This was followed by a slight diarrhœa, and since that ceased she has had a natural motion every day. The sphincter ani has quite recovered its injury and contracts firmly. The artificial opening was prevented from contracting by means of a plug of gutta percha attached to a plate of the same material kept in position by a bandage. This was removed once or twice a day. Since the communication has been restored, the plug has been discontinued so as to allow the opening to contract. The woman is in robust health. Two excellent water colours of the case in different stages were submitted to the Society, and a temperature chart, the novel feature of which was, that most of the observations had been made in the cæcum through the artificial opening.

THE VIVISECTION BILL.

The bill "to prevent cruel experiments on animals," which was recently presented to the house of Lords by the Earl of Carnarvon, has been printed. The preamble declares the object of the bill to be to extend the law relating to cruelty to the cases of animals which for medical, physiological, or other scientific purposes are subjected, when alive, to experiments calculated to inflict pain, and the following are the principal clauses by which it is sought to effect that result:—

A person shall not perform on a living animal any experiment calculated to give pain except subject to the restrictions imposed by this act. A person performing or taking part in performing any experiment calculated to give pain, in contravention of this act, should be guilty of an offence against this Act, and shall, if it be the first offence, be liable to a penalty not exceeding £50, and if it be the second or any subsequent offence, be liable, at the discretion of the court by which he is tried, to a penalty not exceeding £100, or to imprisonment for a period not exceeding three months.

The following restrictions are imposed by this Act with respect to the performance on any living animal of an experiment calculated to give pain; that is to say—1. The experiment must be performed with a view only to the advancement by new discovery of knowledge which will be useful for saving or prolonging human life or alleviating human suffering; and 2. The experiment must be performed in a registered place; and 3. The experiment must be performed by a person holding such licence from one of her Majesty's Principal Secretaries of State, in this Act referred to as the Secretary of State, as in this Act mentioned; and 4. The animal must, during the whole of the experiment, be under the influence of some anæsthetic of sufficient power to prevent the animal feeling pain; and 5. The animal must, if the pain is likely to continue after the effect of the anæsthetic has ceased, or if any serious injury has been inflicted on the animal, be killed before it recovers from the influence of the anæsthetic which has been administered; and 6. The experiment shall not be performed as an illustration of lectures in medical schools, hospitals, colleges or elsewhere; and 7. The experiment shall not be performed for the purpose of attaining manual skill.

"Provided as follows, that is to say:—1. Experiments may be performed under the foregoing provisions as to the use of anæsthetics by a person giving illustrations of lectures in medical schools, hospitals, colleges, or elsewhere, on such certificate being given as in this Act mentioned, that the proposed experiments are absolutely necessary for the instruction of the persons to whom such lectures are given with a view to their acquiring knowledge which will be useful to them for saving or prolonging human life or alleviating human suffering; and 2. Experiments may be performed without anæsthetics on such certificate being given as in this Act mentioned that insensibility cannot be produced without necessarily frustrating the object of such experiments; and 3. Experiments may be performed without the person who performed such experiments being under an obligation to cause the animal on which any such experiment is performed to be killed before it recovers from the influence of the anæsthetic on such certificate being given as in this Act mentioned, that the so killing the animal would necessarily frustrate the object of the experiment, and provided that the animal be killed as soon as such object has been attained; and 4. Experiments may be performed not directly for the advancement by new discovery of knowledge which will be useful for saving or prolonging human life or alleviating human suffering, but for the purpose of testing a particular former discovery alleged to have been made for the advancement of such knowledge as last aforesaid on such certificate being given as is in this Act mentioned that such testing is absolutely necessary for the effectual advancement of such knowledge.

"The substance known as urari or curare shall not for the purposes of this Act be deemed an anæsthetic.

"Notwithstanding anything in this Act contained, an experiment calculated to give pain shall not be performed on a dog or cat.

"Any exhibition to the general public, whether admitted on payment of money or gratuitously, of experiments on living animals calculated to give pain shall be illegal. Any person performing or aiding in performing such experiments shall be deemed to be guilty of an offence against this Act, and shall, if it be the first offence, be liable to a penalty not exceeding £50, and if it be the second or any subsequent offence, be liable at the discretion of the court by which he is tried to a penalty not exceeding £100, or to imprisonment for a period not exceeding three months. And any person publishing any notice of any such intended exhibition by advertisement in a newspaper, placard, or otherwise, shall be liable to a penalty not exceeding £1. A person punished for an offence under this section shall not for the same offence be punishable under any other section of this Act."

By the subsequent clauses it is enacted that the licence is to be granted for such time as the Secretary of State may think fit, and may be revoked. Any licensed person is to make such reports as may be required, and all registered places are to be visited by inspectors. Rules are given as to the certificates of scientific bodies, and the judges are given power to grant a licence for an experiment when it may be necessary in a criminal case. With regard to the legal proceedings to be taken against offenders, it is provided that any justice may grant a search warrant, and the prosecution is to be in any court of summary jurisdiction. An accused person may elect to be tried on indictment before a jury, and in England, if summarily convicted, he may appeal to the quarter sessions.

Surgeon-General James Mouat, V.C., C.B., in accordance with a new Medical Circular which makes retirement compulsory on reaching a prescribed age, has relinquished the position of chief medical officer of the Southern Military District, in which office he has been succeeded by Deputy Surgeon-General H. Lionel Cowen. In causing the above information to be published in orders, Lieut.-General Sir Hastings Doyle, Commanding-in-Chief, remarks that he cannot allow Surgeon-General Mouat to leave the garison without his receiving from him an expression of his deep regret at losing his valuable services, and of his high sense of the zeal and energy invariably displayed by the doctor in the performance of his onerous duties.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, MAY 24, 1876.

THE STUDY OF FORENSIC MEDICINE.

When in our article upon the "Conjoint Board" we insisted on the necessity of candidates showing a fair knowledge of forensic medicine before obtaining their certificate to practise, we little thought that the truth of the principle we then inculcated would be so soon and so forcibly attested as it has been by the mysterious death which has recently occurred at Balham. When commenting on the new conjoint scheme we took occasion to regret that forensic medicine was not put down among the subjects on which the future candidate would be examined by the Board. The comparatively unimportant subject of medical botany was specified in connection with materia medica, but no mention was made of forensic medicine and toxicology. We were the more surprised considering the great practical importance of a knowledge of this department of medicine to gentlemen engaged in general practice, and considering "that the candidate has scarcely obtained his diploma before he may be called upon to recognise and to treat a case of poisoning," or to have his knowledge of forensic medicine put to the test in some other way. The sad and very lamentable occurrence at Balham shows how suddenly the general practitioner may be called upon to give a really practical demonstration of his skill and promptitude in handling a case of acute poisoning—what serious consequences might result from his failing to recognise the nature and gravity of such cases, and how possible it may be even for the ends of justice to be defeated through the ignorance or negligence of the medical attendant. We cannot, perhaps, in the exercise of our profession fall into a more serious error than that of mistaking a case of poisoning for one of natural disease, or a case of natural disease for one of poisoning. And yet, as we all know, there are cases which may puzzle well-educated and experienced members of the profession, much more those whose information in this department of medicine is very imperfect, or which has never even been tested. With respect to this case at Balham, which is by no means so obscure as some that have happened, a leading public journal went so far as to say that until one of the witnesses, an eminent physician, was called in, there was no suspicion that the unfortunate gentleman had taken poison, and that had he not been in the position to pay for the best advice in London, his death would have been ascribed to dysentery or to some form of cholera, and no inquest would have been held. We are glad to see that this hasty and intemperate statement has been contradicted, and we quite believe Dr. Harrison when he says that both he and Dr. Moore "were convinced that the deceased was suffering from the effects of some irritant poison some time before he was seen by any other medical men." But still it must be admitted that what has been erroneously asserted in respect of this case has really happened over and over again, and would happen more frequently were it not that forensic medicine has been long recognised as a separate branch of study at all our medical schools, and were it not that the majority of general practitioners have the certificate of a licensing body which has never neglected that important branch of practical medicine.

Although tartar emetic is one of those poisons the effects of which may be, and often have been, mistaken for those of disease, we are not surprised that in this particular instance the suspicions of the medical attendants were very soon aroused. All the more reliable symptoms of poisoning were present. The symptoms came on suddenly without any warning, and were very alarming in their severity. They came on soon after a meal in a man who was previously in the best of health, and who had not been exposed to any of the ordinary causes of disease. Moreover, the irritating and depressing nature of the poison was shown by the great failure of the heart's action, the vomiting and purging, the severe pains and cramps in the stomach and bowels, the distressing tenesmus, and the admixture of blood with the vomited matters and the fæces. At the same time there was much to make a medical man hesitate before pronouncing such a case to be unmistakably one of acute poisoning, and some of the symptoms just mentioned might at the outset have been attributed by a careless observer to an attack of English cholera, or to enteritis, or even to dysentery. Many years ago Dr. Taylor remarked that "many acquittals on criminal charges have taken place from the great difficulty which exists in distinguishing English cholera from arsenical poisoning, and that if in any case medical evidence rested upon symptoms alone, it would be scarcely possible in some instances to draw such a clear distinction between the symptoms of this disease and those of poisoning as the law would deem absolutely necessary for conviction." Now what has been said in respect of arsenic is far more true in respect of antimony, a poison whose effects upon the system are far more likely to be attributed in almost any case to those of natural disease than arsenical poisoning would be, and which, for that very reason, has been more frequently used for criminal purposes than for the sake of self-destruction. It is not only quite possible, but very probable, that had Mr. Bravo been attended by only one medical man, and had that medical man had no suspicion of the real nature of the case, the death of the deceased gentleman might have been set down to natural causes, and might have even

escaped the scrutiny of a coroner's inquest. It is, however, this very element of uncertainty in the diagnosis of some cases of poisoning that makes it all the more imperative for those who are responsible for the qualifications of the general practioner to see that his credentials to practise are such as to reduce to a minimum the chance of his committing in such cases any grave mistake, and perhaps of his becoming unconsciously an abettor in the screening of a criminal from the punishment he deserves. But this security cannot be ensured if the study of forensic medicine as a special department of medical education be neglected, and if examining boards fail to demand from their candidates a fair knowledge of that important branch of practical medicine.

This affair at Balham is all the more shocking from the peculiarity of the circumstances attending it, and the mystery in which it appears to be involved. But out of such evils some good often arises, if only they show that no part of a general practitioner's education can be neglected any defect in which would be in the least wise prejudicial to the interests of society.

"HODDING."

Our readers will recollect that some months ago a pharmaceutical *furore* was excited in England by the publication of a Report by Mr. Allen, the Public Analyst for Sheffield, of the result of his examination of a number of bottles of medicine dispensed according to a given prescription in various pharmacies in his town, which investigation divulged the fact that hardly one of the dispensers had taken the trouble to weigh the ingredients, and several of them had grossly defrauded the customer and the prescriber by omitting or curtailing some of the constituents of the prescription. This report of Mr. Allen excited—as might have been anticipated—a tempest of protestation on the part of the pharmaceutists and their journalistic representatives, who affirmed that their trade ought not to be judged by the acts of a couple of dozen dispensers in a low locality of a manufacturing town, and they called for vengeance on the analyst who had identified them with such practices.

Within the last fortnight, however, Mr. William Thomson, of the Manchester Royal Institution, has published the result of nearly 200 analyses of prescriptions, compounded, not in any one town, or in any one locality, but throughout all parts of England and in eighty-one separate establishments, and he has placed it beyond doubt that, as a rule, great irregularity and carelessness exists amongst English pharmacists, amounting in some instances to dishonest subtraction of important ingredients, greatly to the prejudice of the medicine prescribed, and no doubt to the disappointment of the physician who prescribed it. The prescriptions were a mixture of potassium iodide and spirit of chloroform and a lotion of sulphate of zinc.

Mr. Thomson says:—"In looking over the above table it will be seen that only two druggists out of the eighty-one have given the exact weight of potassium iodide; thirty-four have given *more* than the prescribed amount, and forty-five *less*; but it may be of further interest to notice that when the whole of the quantities of potassium iodide given by the eighty-one different druggists are added together the total quantity comes to 220½ grains less than it would have been if each druggist had dispensed the exact quantity. Again, in the lotion, only one druggist out of the eighty-one gave the exact weight of zinc sulphate; forty-three have given *more* than the prescribed amount, and thirty-seven *less*; and when the whole of the quantities of the zinc sulphate given by the eighty-one different druggists are added together it comes to only 12½ grains *more* than it would have been if each druggist had dispensed the exact quantity."

In other prescriptions, containing quinine, nitrate of silver, and other expensive drugs, the errors were shown to be much larger, and always on the side of a subtraction of the costly ingredient, the 60 grains of silver nitrate or quinine being represented in some instances by 42 and 44 grains, while in the case of the potassium iodide solution the 120 grains prescribed were reduced by some of the pharmaceutists to 44 or 60 grains. In several instances other ingredients were omitted altogether, the result of which was the deposition of a sediment or the insolubility of the quinine. Finally, it appears that, as to price there is an extraordinary diversity of practice; for the potassium iodide and the zinc sulphate prescriptions the prices varied between 9d. and 2s. 9d. Of the eighty-one prescriptions, sixteen cost not more than 1s. 6d., while sixteen others cost 2s. 6d. or more.

This inquiry is of much interest to the medical profession in England, and we give publicity to it because we observe that an effort has been made by the Pharmaceutical Society to withhold Mr. Thomson's facts from the public knowledge. The paper in which they were embodied was forwarded to the Committee of the Society, accepted by them—we suppose without careful perusal—and afterwards rejected on the day on which it was to have been read before the members. Consequently Mr. Thomson was obliged to read it before the Manchester Philosophical Society, where one of the debaters appealed to Mr. Thomson "not to publish it in the papers."

The investigation, which seems to us to have been carried out with an accuracy which leaves no room for doubt as to the facts, proves that while a certain small number of pharmaceutists, even in the best localities, are not only negligent, but dishonest in their dispensing of prescriptions, the great majority are guilty of no greater offence than that of "hodding," or guessing quantities which should be carefully measured or weighed. It also proves that medicines dispensed in such a way are liable to serious errors in quantity, even when as much care is exercised as is usual in the hasty compounding of a large pharmacy. Furthermore, it is plain that medical men have good occasion for suspicion when they find that a medicine containing a quantity of expensive drugs does not produce a satisfactory effect, and will do well to be vigilant in the interest of the patient and of their own good name. Lastly, it is pretty evident that a dispenser who gives 44 grains for 120 of potassium iodide, 8 grains for 40 of sulphate of zinc, or 42 for 60 of quinine, is a rogue, and when detected, should be prosecuted.

Altogether, Mr. Allen and Mr. Thomson have disenchanted the profession, and given them good reason for caution in pharmaceutical matters, and the Pharmaceutical

Society have added to these suspicions by endeavouring to "burke" the inquiry.

THE SURGEON-OCULIST TO THE QUEEN IN IRELAND.

THIS distinction, which has been the subject of competition between the leading ophthalmic surgeons of Ireland has been conferred on Mr. Charles Fitzgerald.

The selection is one which the MEDICAL PRESS AND CIRCULAR would fail in its duty if it recorded without comment as to its propriety. It is, or ought to be, the blue riband of ophthalmology in Ireland—was conferred on Sir William Wilde only when he had reached the summit of his professional success, and was held by him as, after the retirement of Dr. Arthur Jacob, not only the senior, but as admittedly the highest authority on eye surgery in Ireland. On his death the honour was sought by Dr. Archibald Jacob, an ophthalmic surgeon of sixteen years' standing, who is on the Council of the Royal College of Surgeons, and who has held the surgeoncies of public hospitals and other offices of honour in the profession; and by Mr. Wilson, the successor to Sir William Wilde in St. Mark's Hospital, the Professor of Ophthalmology in the Irish College of Surgeons, and Examiner in the University of Dublin, and whose standing in the profession is about equivalent to that of Dr. Jacob. Next in seniority to these gentlemen is Dr. Swanzy, who has been just ten years in the profession, and holds the ophthalmic surgeoncy of the Adelaide Hospital.

Mr. Fitzgerald, whom Her Majesty's adviser in such matters has selected, is three years Mr. Swanzy's junior, and is that gentleman's assistant in a small proprietary ophthalmic institution. He is also surgeon in charge of the ophthalmic speciality at the Richmond Hospital, without regular appointment, and with the charge of about four beds. His first entry into public ophthalmic practice was as Mr. Swanzy's assistant, five years ago, and his connection with the Richmond Hospital just three years. His announced contributions to ophthalmic literature consist of three papers in professional journals.

While we feel that justice to Mr. Fitzgerald's less successful competitors obliges us to state these facts, we emphatically repudiate the least desire to depreciate that gentleman's position. He is without doubt a young man of promise, who, by industrious application to his speciality for ten or fifteen years, might very probably merit Her Majesty's decoration; and no doubt the fact that his father is a judge and his uncle a bishop must have impressed Her Majesty's adviser with confidence in the future of a gentleman who possesses hereditary qualities of such value. The little that he has written or done gives evidence of culture and skill only requiring experience for its development.

We have reason to believe that he has been fully conscious that his professional standing gave him little claim to such a distinction, and he has not in any way forced his pretensions upon those authorised to make the selection for Her Majesty, his name having been put forward by friends whose action we consider to have been most injudicious. Sympathising with Mr. Fitzgerald's feeling in the matter, we the more regret that his pretensions should be exposed to public criticism, which cannot but prove adverse, but we touch the subject for the purpose of protesting with all vehemence against the present system of selection for the medical distinctions conferred by Her Majesty in Ireland.

Had the opinion either of the profession or of the public in Ireland, or even of any considerable section of them, been taken as to the surgeon entitled by attainments, position, or seniority to Her Majesty's consideration, we do not hesitate to say that Mr. Fitzgerald's name would not have occurred to any one's mind. If either Her Majesty's medical or her political advisers in Ireland had been allowed to give their verdict, we believe ourselves entitled to state that the same would have been the result. We hold that etiquette and expediency should both influence the Queen's adviser to consult the Queen's surgeons and physicians in Ireland on such a subject, and we are bound to say that the omission to do so has connected Her Majesty with a grievous mistake, which the profession in Ireland will interpret to be nothing less than an indefensible job. If surgical honours in Ireland are in future to be distributed at the suggestion of a London official who himself has only the most imperfect sources of information—if those who are acknowledged to be first in their speciality and in social position are to be set aside for youthful claimants whose qualities have yet to be manifested, these distinctions will cease to be an honour, and will be shunned by those whose position ought to entitle them to a mark of Her Majesty's approval.

THE GOVERNMENT VIVISECTION BILL.

WE give in another column an abstract of the Bill which Lord Carnarvon has introduced into the House of Lords entitled "An Act to Prevent Cruel Experiments on Animals." It appears that experiments "calculated to give pain" will henceforth have to be performed only in registered places by persons holding a licence from the Secretary of State, and "under the influence of some anæsthetic of sufficient power to prevent the animal from feeling pain," and if serious injury has been inflicted on the animal it must be killed before the effect of the anæsthetic subsides. This latter is a doubtful provision, and, of course, must add to the number of animals slaughtered during the year. The exception to the prohibition, however, is "demonstrational experiments absolutely necessary" for the instruction of students, and made with a view to their acquiring knowledge which will be useful to them for the purpose "of saving or prolonging human life or alleviating human suffering," and then even the anæsthetic state must be secured. The next provision is one calculated to give annoyance and trouble, for it is provided that whenever the object of an experiment intended for purposes of research cannot be attained without giving pain to the animal, a special certificate to that effect is to be required from a properly constituted scientific authority, who, we suppose, is to be the judge of the pain suffered by the animal. A good deal of official trouble will be involved if the clause remains which requires an accurate report to be made to the Secretary of

State of all experiments made, and if not given in a proper form, the licence may be revoked; and with singular perversity, the use of curari as an anæsthetic is to be prohibited, and dogs and cats are to be exempted from all experiments. Teachers of physiology must look closely to the provisions of the Bill, otherwise we fear they may find its requirements a long way beyond "the bounds dictated by humanity."

Notes on Current Topics.

Uncertified Deaths.

Attention is drawn by the Registrar-General to the fact that during the three weeks ending the 6th inst. the causes of no less than 13 per cent. of the deaths registered in Peckham were uncertified either by registered medical practitioner or by coroner. This unsatisfactory condition of the death register is, he says, mainly due to the employment of unqualified assistants by medical practitioners in that neighbourhood. It is pointed out that when patients are exclusively attended by unqualified assistants, no legal certificate of the cause of death can be obtained unless an inquest be held.

If it be true that the great number of uncertified deaths is due to the employment of unqualified assistants, some discredit must fall upon the employers. There are a large number of medical men throughout the kingdom employing unqualified assistants, and though we would gladly see such assistance discontinued, we see no means of avoiding it at the present time. We believe it to be the rule however that an unqualified assistant does not attend any case through an illness, but acting with his employer, sees the patient alternately with the qualified practitioner, or more or less often according to the particular circumstances of each individual case. Every case therefore is or ought to be literally under the care of the medical practitioner, and not under the care of the unqualified assistant, in which case the certificate of death would be signed by the practitioner. If any surgeon leaves a case entirely in the charge of his unqualified assistant, we cannot but think that he is greatly to blame. He is responsible to all his patients for their proper treatment, and if so heavily worked that he cannot attend to all, it is at least his duty to provide attendance by one who is recognisably qualified. If unqualified assistants are to be allowed to have sole charge of cases, it will be as correct to sanction the formation of dispensaries under unqualified medical officers. It would be a satisfaction to hear from the registered practitioners residing in Peckham that some error has accidently crept into the report of the Registrar-General; but if, on the other hand, the statement is correct, that the excessive number of uncertified deaths is due to the cases having been under the medical attendance of unqualified assistants, we must call the attention of those practitioners to an error in their practice which it is their duty at once to rectify.

Self-Development of Ova.

Dr. Moquin-Tandon, of Paris, gives some remarkable observations made on the unimpregnated eggs of frogs, showing a limited power of self-development. The process was more rapid than in fecundated eggs which were allowed to develope at the same temperature. Only a small number of the ova presented this evidence of commencing development; the majority died without sign of segmentation. In all cases the phenomena soon ceased, the spherules produced soon separated, and the whole mass began to decompose. M. Moquin-Tandon points out that the observation establishes incontestably that the ova of vertebrata not impregnated by spermatozoa may pass through the earliest stage of development in certain conditions, the exact nature of which is at present unknown. These facts may be placed beside those of the same kind observed by Bischoff on the sow, by Hensen on the rabbit, by Agassiz and Burnett on fish, and especially with the remarkable fact observed by Oellacher that in fowls kept far from a cock unfecundated eggs undergo segmentation in the interior of the oviduct.

Vitality of Ova.

The degree of cold which a hen's egg can bear without losing its power of development has lately been investigated by M. Colasanti. Having first observed that salt water at ordinary temperature did not affect the development of eggs, he buried some eggs in a freezing mixture of ice and ordinary salt. Of any three or four treated thus one or other always breaks its shell; and the contents both of these and of the unbroken ones were found solidly frozen. After remaining one to two hours in the mixture (the temperature of which quickly went down to —7 deg. to —10 deg. for 30 to 40 minutes, rising again to —4 deg. or —5 deg. by the end of the second hour), the unbroken eggs were taken out, washed and dried, and placed in the hatching oven, having a temperature between 36 deg. and 40 deg.; and after ten days they were examined. In every case a normal embryo was found to be developed, without the least trace of anomaly. They were in all respects like the normal embryos of eggs that had been placed in the hatching oven without previous exposure to cold. M. Colasanti remarks that the fact is in harmony with a large number of other natural history facts, which altogether show that the germs of organisms possess a considerably greater power of resistance than the completed organisms themselves.

Rapid Death from Snake-bite.

The last number of our contemporary the *Melbourne Medical Record* contains an account of the death of a man from snake-bite in the shortest time, we believe, on record. The person referred to, named Wilson, had placed his foot on a snake about seven inches from its head, put his hand down to seize it, and was bitten on the finger. He then took hold of the tail and lifted the snake, striking its head repeatedly against the door. He showed his finger where the marks of the bite were visible, but refused to allow it to be interfered with. He went out, and returned in a few minutes and fell into the arms of a man present. A few convulsive struggles and life was extinct. The time from the bite to the death was from eight to ten minutes.

Infusoria in Fever Stools.

Dr. Felix Marchaud, of Berlin, reports in Virchow's *Archiv* the case of a young man, aged fifteen, suffering from enteric fever, in whose stools, in addition to bacteria, he observed infusoria in a state of great vital activity several times during the early stages of the disease. They were of a roundish triangular form, compressed laterally, the posterior angle was elongated into a long cilia-like tail, and some long cilia were placed round a depression near the front of the ventral surface. To these structures the rapid movements of the animal were doubtless owing. In the interior were seen some granules and one or two vacuoles. In addition to these forms were others which exhibited motions rather of an amœboid character, but which, however, possessed cilia and vacuoles which the author regards as the imperfectly-developed condition of the former. The disease ran a moderately severe course, and ended in recovery.

Kryolite.

Epsom salts is very largely manufactured in Philadelphia from the mineral called kryolite. One house has the monopoly of this substance, which is obtained from the coast of Greenland. The importations since June, 1874, are valued at over 80,000 dollars. Kryolite is a soft magnesian mineral.

Liberation of Heat on Blood Coagulation.

It is well known that the passage of a body from the liquid state to the solid is accompanied with liberation of heat; and it is not surprising that the same should occur in coagulation of the blood. M. Lepine has been making exact experiments on this. He has demonstrated that the temperature of the blood of a dog, about four minutes after it has been taken from the artery, presents an elevation of several tenths of a degree (generally more than one degree), for about four minutes, and then the blood cools progressively. At the first moment of fall of the mercurial column, one may assure oneself, by drawing the thermometer from the vessel, that the blood is completely coagulated. Considering the small quantity of fibrin contained in the blood, relatively to the whole mass of the liquid, M. Lepine is disposed to doubt whether the heat observed is due solely to the physical phenomenon of change of state of the fibrin; and in some cases the heat observed was very small, almost *nil*. He thinks the phenomenon rather one of a chemical order.

The Skin and Bodily Temperature.

The *Philadelphia Reporter* quotes the following conclusions given by Dr. Winternitz, on the importance of the cutaneous function with regard to the heat of the body. His paper is given in Stricher's *Jahrbücher:*—

1. The increase and diminution of loss of heat from the skin can be stated approximately in figures.

2. Experiments show that the giving off of heat may vary more than 60° downward, and more than 92° upward.

3. Such a variation in loss of heat can compensate variations in the production of heat three times the normal amount.

4. The discoverable variations in the loss of heat suffice to explain the constancy of temperature, so far as it exists under the usual cooling and warming influences.

5. The diminution in the loss of heat, consequently its retention, after previous loss, even if the production remain constant, is sufficient to replace in a short time the loss of temperature.

6. A diminution in the loss of heat alone can in many cases explain a febrile rise of temperature.

7. The possible increased loss of heat of more than 92° explains the frequently observed rapid disappearance of fever.

8. There is, consequently, no doubt that one of the most important factors in the regulation of temperature is to be found in the function of the skin.

Small Pox and Vaccination.

The Toronto *Sanitary Record* says that nearly one-eighth of all the deaths in Montreal in 1875 were from small-pox. The number was 784, and of these 653 were French Canadians. There is a ready explanation of this wanton slaughter. A crusade was got up against vaccination mainly by one or two French physicians, who availed themselves of the ignorance and prejudice of the French Canadian population to foment a fanatical opposition to the practice, which even broke forth on some occasions into mob violence. Posterity should build a monument to anti-vaccinationists, constructed like some monuments we read of in Africa, of the skulls of their victims.

The Plague in Mesopotamia.

A bulletin of the Sanitary Board issued last week shows a serious increase of the plague at Hillah and Bagdad, but happily no extension of the epidemic outside the circle now enclosed by a sanitary cordon. At Bagdad, from the 16th to the 22nd April, there were 336 fatal cases, or an average of 48 per day. At Hillah, 159 deaths were registered during the same period, or an average of 22 per day. Some isolated cases, too, are reported from Imam-Mousa and Nedjef, but these localities are within the sanitary cordon, outside of which, up to the 22nd inst., no instance of plague had occurred. According to private information we have received, the number of deaths at Nedjef was 11 from the 16th to the 21st of April, and at Imam-Mousa (a village within an hour's distance of Bagdad) 7 from the 15th to the 19th.

The Typhoid Epidemic at Croydon.

The report of Dr. Buchanan to the Local Government Board on the origin of an epidemic of typhoid fever which occurred at Croydon in 1875 has just been issued. He thinks this was caused by the escape of infected air from the sewers, and remarks that hardly anywhere in Croydon can there be found an arrangement for severing the sewer from the air of the house-drain. There was also reason to believe that polluted water played some part in the phenomena of the epidemic; but he thinks the water had much less to do with the fever than the sewer gas. He makes a variety of suggestions to prevent a recurrence of the fever.

Sir John Cordy Burrows.

At an influential meeting at Brighton it was resolved to erect some public memorial to the late Sir Cordy Burrows, who was to have presided at the meeting of the British Medical Association in Brighton this year. An influential committee, comprising the borough members and member for East Sussex, was appointed.

Sewage Experiments.

In response to an invitation issued by the Sanitary Carbon Company, a number of gentlemen interested in the purification of sewage effluents met recently at Mr. Campbell's Model Sewage Works, Wandsworth Road, to witness some experiments illustrative of the disinfecting and decolorising action of a peculiar form of carbon, first introduced to public notice at the Social Science Congress at Brighton last autumn. This material, to which has been given the name of "Sanitary Carbon," is the residual coke obtained in the manufacture of gas from blackstone, or bituminous shale, a substance found in large quantities in Dorsetshire. This residue differs from ordinary coke in having a large admixture of earthy matters and possessing decolorising, deodorising, and purifying properties similar to those of animal charcoal, and is scarcely, if at all, inferior in its action. The purposes to which it is proposed to apply it are the final clarification by filtration through it of sewage effluents after the great bulk of their impurities have been removed by some one of the many precipitation processes now in use, and also the decolorisation and clarification of the waste liquors or effluents from dye-works, &c. The experiments performed under the direction of Mr. C. W. Wollaston conclusively proved the efficacy of the new filtering medium for the purposes referred to, raw and precipitated sewage and water darkly coloured by various kinds of dies and colouring matters, both vegetable and mineral, being thoroughly and rapidly rendered clear and colourless by a single filtration.

Accidental Poisoning.

An inquest was held at Wormleighton, near Banbury, on Saturday, on the body of the Rev. Reginald Hibbert, D.D., rector of the parish. It appeared that the deceased complained of a headache, and had been in the habit of using chlorodyne, but some chloral having been put in a chlorodyne bottle, he had taken an overdose of chloral by mistake.

The circumstances are somewhat curious. It appears difficult to mistake chloral for chlorodyne, or to take an overdose of the one—the supposed correct dose of the other. A verdict to the above effect was returned.

The New Metal, Gallium.

M. Wurtz has presented to the Académie de Sciences three specimens of the new metal which was recently discovered by M. Lecoq de Boisdandron. The new metal is solid and malleable, and of a silvery bluish-white colour. Its density is between those of aluminium and indium. It can be produced in a crystalline form, which is obtained by the electrolysis of gallium chloride dissolved in ammonia or potash. Unfortunately, gallium is the most fusible of all metals, and becomes liquid at a temperature of 29° (Centigrade). This, the *Paris Medicale* remarks, will render it of little use in the manufacture of spoons, unless for the purpose of eating ices. Gallium is therefore condemned to remain a curiosity of the laboratory until someone shall discover to what uses it can be applied.

Novel Treatment of Obesity.

The *Paris Medicale* discusses the treatment of obesity by the administration of sea-water combined with a residence at the sea-side. Sea-water, taken internally acts like diuretic and purgative salts, a remarkable fact being that the diuretic effect increases when the purgative diminishes. The water should be obtained, when possible, from some depth, and far from the shore. It is then to be left to settle for six to twelve hours, and filtered. It is to be taken three times a day in doses of a small tumbler glassful, or in half that quantity at a time with fresh water or milk. It is stated as a fact that sea-water thus used facilitates the oxygenation of the blood, and that it hastens the elimination of effete materials. In combination with this treatment sea-water baths are to be taken, free exercise is to be carried out, and at the same time fattening foods are to be avoided. Cases which have resisted other measures are stated to yield to this treatment.

Frauds upon Medical Men.

In a recent number we cautioned our readers that a woman was going the round of the houses of members of the profession, sending them upon a fool's errand to some very important case where she stated their presence was immediately required, and in their temporary absence pocketing any little articles upon which she could lay her hands. The extent of these frauds may be gathered from the report of a case which occupied the attention of one of the London magistrates on Friday last, and we rejoice that at least one of these female marauders is safely in custody. The thief in this instance is the notorious Mina Jury, one of the most prominent witnesses in the Tichborne case. She was charged with no less than twenty-two robberies, nearly every one committed at the houses of medical men.

The mode generally adopted by the prisoner was to make a statement at the house of one of these that his services would be required on the following day, upon which he called. She as a rule came when the doctor was absent, and, while waiting, managed to carry off various articles. The evidence showed that a few days back prisoner paid a visit to the house of Mr. Philp, surgeon, of Peckham, and after she left a gentleman named Cole, residing in the same house, saw some portion of a travelling rug extending beyond the folds of a large cloak worn by prisoner. The travelling rug of Mr. Philp was then missed from the consulting room in which the prisoner had been, and found in her possession, though upon being given into custody declared it was her own. Upon her was found two tobacco pouches, a cigar case, surgical instrument, and a box of cigars. These articles were identified as the property of Mr. Morden Wright, surgeon, of Walworth Road, and his assistant. It was shown that prisoner had paid a visit to Mr. Wright, and said he would be wanted to attend a lady. In the temporary ab-

sence of the assistant the prisoner managed to take the articles found upon her. It was now stated that on the 4th inst. the prisoner visited the house of Mr. Bebett, surgeon, of Cambridge Road, Hammersmith, and after she left a case of instruments valued at about £15 was missed. In the next case prisoner went to the house of Dr. Pink, of Croom's Hill, Greenwich, under the pretence that his services were required, and after she left a case of surgical instruments valued at £7 was missing. In another case the prisoner on May 9 went to the house of Mr. Jameson, dentist, of 30 High Street, Camden Town, and stated that a lady in Edward Street, Hampstead Road, required him to visit her. After she had left a large clock from the sideboard was missed. It was worth about £8. The prisoner declared that the rug said to belong to Mr. Philp was her own, and denied that she had ever been near any of the places mentioned by the witnesses. She declined to make any further defence. The magistrate strongly animadverted upon the carelessness of the pawnbrokers who had received the articles in pledge without proper inquiries; it was almost holding out a premium for dishonesty. He then committed the prisoner for trial at the next Old Bailey Sessions.

Typhoid Fever at Rome.

Sir Robert Rawlinson writes, warning persons visiting Rome of the risks incurred from typhoid fever in the present insanitary state of the city. The site of the city has a subsoil bearing the saturation of ages of human occupation; the houses are old and musty, and the hotels have in some instances sanitary appliances added without the necessary precautions to prevent atmospheric contamination. That fever should be the result is only in the natural order of things. To remove entirely all the sources of fever from Rome will be a laborious and costly proceeding, as new sewers and drains will be required, and if these are not designed and executed upon correct principles they had better be left alone, as stirring up old accumulations is about the most deadly operation men can be engaged in. Then as to the recent so-called improvements in hotels—that is, the introduction of modern water-closets within the body of the building, to be connected with old drains and cesspools—no more deadly contrivance could be invented, as the leaven of the old site and tainted subsoil will set up putridity in the matter discharged from the new closets, generating and pouring out noxious gases. Introducing English water-closets into old hotels, without a proper water supply, full ventilation, and proper drainage, will only make a new source of danger; and if these closets are within the body of the building and adjoining bedrooms the danger will be the greater. Reliance on disinfectants is never safe. If any Roman hotel proprietor wishes, however, to have English water-closets, let him place them outside the walls of the hotel, at the end of a corridor or passage, and let there be daylight, and full ventilation to the open air at the ceiling, and let the closet pipe be carried above the roof and have its full diameter open. Such a closet may then be used safely and the internal atmosphere of the hotel will not be contaminated. Closets in small rooms within the body of the hotel, having no daylight nor any ventilation, should be avoided as a dose of known poison would be avoided.

The London Water Supply.

Dr. Frankland reports that the excessive pollution of the Thames which occurred in March had somewhat abated, whilst that of the Lea had altogether ceased, when the samples were taken on the 18th of April. The water delivered by the Chelsea and Southwark and Vauxhall Companies was slightly turbid from imperfect filtration. These waters contained moving organisms, and that of the Southwark Company confervoid growths. The Kent Company's water from deep wells was clear, brilliant, and wholesome. We learn from a report in the papers that a Mr. Hopping, of High St., Barnes, was last week summoned at the instance of the Richmond Rural Sanitary Board for using polluted water drawn from a well on his premises. The medical officer of health said he had analysed the water, and found it very foul through percolation from a cesspool. In reply to the magistrate, the witness said it was more impure than the water supplied by the Southwark Company. The witness said he had no interest in the Water Company, beyond drinking their water and paying their rate. The defendant consented to an order to use the water for trade purposes only.

A Mysterious Death at Balham.

Mr. Charles Delauney Turner Bravo, a young barrister of wealth and position, was, on Tuesday, April 18th, taken suddenly ill with symptoms of poisoning, from which he died after an illness of fifty-six hours. An inquest was held upon the body at which important witnesses were not allowed to give evidence, and the jury, who were apparently dissatisfied with the evidence given, brought in a verdict "that the deceased gentleman died from the effects of antimonial poison, but how or by whom the poison was administered there was no evidence to show."

It appears that Mr. Bravo, in his usual good health and spirits, on the day mentioned dined with his wife and a widow lady who resided with them in the capacity of a companion to Mrs. Bravo. They partook of the same food in every item with the exception of some Burgundy wine, of which neither Mrs. Bravo nor the companion, Mrs. Cox, drank. Of this wine a quantity was left, but what became of the remainder was not made known. It is *stated* that Mr. Bravo went to his bedroom at *half-past nine*, and when there he called for some warm water. Mrs. Cox then found him vomiting *out of window*. It seems strange that he should have chosen to vomit out of window instead of into a convenient utensil; however, the vomit lodged on a parapet, and the quantity which was collected by order of Dr. George Johnson was found by Professor Redwood to contain over ten grains of antimony.

When Mrs Cox discovered that Mr. Bravo was ill she asked him what was the matter, and her account is that he replied, "Oh, I have taken poison; but do not tell Florence" (his wife). Dr. Moore and Dr. Harrison were sent for, and though in attendance, no mention of the poison was made to either medical gentleman for four or five

hours, according to the admission of Mrs. Cox, who stated in evidence that she had told Dr. Harrison four or five hours after, but on that gentleman denying it, she said she had perhaps told Dr. Moore. Dr. Geo. Johnson arrived at the house in company with Mr. Royes Bell at 2·30 a.m., when they found the patient unconscious, breathing deeply; pulse 100, heart sounds normal, and pupils natural size. He had vomited blood-tinged fluid, and a motion had passed in the bed involuntarily. About 3 o'clock consciousness partly returned, and he recognised Mr. Bell. He then denied having taken poison, but added that he had rubbed his gums with some laudanum. Vomiting and purging, with blood in the motions, continued throughout the day, but his intellect was *clear*.

In the evening he was seen by Sir W. Gull, who, with Dr. Johnson, again begged him to state if he had intentionally taken poison, suggesting that, if he should die, some one might be accused of murder, to which he replied he was aware of it, but could tell nothing more. He died at 5·20 a.m. on the Friday.

Professor Redwood found antimony in the vomited food, in the dark-coloured liquid evacuation, in the urine, and in the contents of the large intestine, but could find none solid in the stomach or intestine. It is strange to say that the coroner, who, we are glad to add, is not a medical coroner, was either totally incapable of dealing with the case, or else he, having in his mind concluded that it was one of ordinary suicide, refused to call evidence as to the food and other important matters, concerning which we must now remain in ignorance. The case is throughout veiled in mystery, but further inquiries are now being prosecuted by order of the Home Secretary.

The Medical Microscopical Society.

This young but useful society has just issued its third annual report, from which we learn that it is steadily progressing towards fulfilling the objects for which it was designed. We are glad to find also that it has proved of considerable advantage to the younger members of the profession in various ways. This society, however, seem to be hardly so well known and appreciated as it deserves which the Committee believes is mainly due to the non-publication of a volume of proceedings. But this cannot be done, owing to the want of funds, and in consequence of the large number of subscriptions being unpaid. Notwithstanding this drawback, its meetings have been well attended, and the discussions on the various propositions and papers brought before the society have been of a most instructive character. We trust to hear in another year that every third year's man in London has joined the Medical Microscopical Society, as they must find it of inestimable value in their pass examination at the College.

The Irish Registration Service.

We understand that Dr. Malachi Burke, the Medical Superintendent of Statistics under the Irish Registrar-General, has been advanced to the office of Assistant Registrar-General, in which capacity he will relieve Mr. Donnelly, the Registrar-General, of a portion of those duties which his age renders too onerous. It is also rumoured that the appointment of Medical Superintendent will not be filled up, but that eventually the office of Registrar-General will be made a medical one, an arrangement which cannot fail to be beneficial to the public service and to the efficiency of this most valuable department. Should such intention be carried out, no doubt Dr. Burke will be the first medical Registrar-General.

The Profession at the Levee.

The following gentlemen were presented to H.R.H. the Prince of Wales on Monday:—Surgeon Alges, R.N.; Surgeon-General Sir Joseph Fayrer, M.D.; Surgeon-General Francis; Fleet-Surgeon Gordon, R.N.; Surgeon T. Gray; Staff-Surgeon McDonnell, R.N.; Mr. Simon, F.R.S., C.B.; Surgeon-Major Thorpe; Surgeon R. Temple Wright, M.D.; and Staff-Surgeon H. C. Woods, M.D.

Foreign Surgeons for the Army.

Some weeks since a statement appeared in the *United Service Gazette* in reference to the future of the Army Medical Service, in the nature of a threat that, if the medical officers continued to give trouble by asking for redress of grievances, or if the profession continued to refuse the terms offered by Mr. Gathorne Hardy, the Government would call in the services of German and other foreign medical graduates, and fill the vacancies in the department with them. This statement would have attracted no attention, but that the *United Service Gazette* has been understood to speak—to some extent—upon the authority of the Medical Director-General, and its pronouncement was therefore looked upon as an unofficial hint on the part of those in authority. The subject having been brought under the notice of the Council of the Irish College of Surgeons, they requested Dr. Brady, M.P., to interrogate the War Minister on the subject. The honourable member did so last week, and received a satisfactory assurance that no such move was intended, and that there was no truth in the statement.

The Vacancies in the Medical Council.

The Crown nomination to the Medical Council, vacant by the death of Professor Parkes, has not yet been filled up; and another seat has fallen vacant by the resignation of Dr. Sharpey, who persists in his intention to retire, although urged to remain with the Council. We have several times urged the appointment of a pure surgeon to one of these vacancies, with a view of equalising in some respect the representation of surgery and medicine in the Council. *The British Medical Journal* demands the selection of a provincial general practitioner, and suggests the nomination of Mr. Simon to the other vacancy on his retirement from the Privy Council Office, which latter suggestion is a happy one, and will, we trust, be acted upon.

Registration of Foreign Degrees.

A petition will be presented to the General Medical Council next week, praying that foreign degrees may be registered if possessed by those who are already entitled to register their names as qualified to practise medicine. British physicians have from an early period of medical history graduated at foreign universities, and the

degrees granted by some universities have been acknowledged by the profession. Without enumerating such universities, we may say that examinations there held are superior to the examinations held at many of our own universities, and therefore the holders of such diplomas may naturally feel themselves aggrieved at not being able to register them.

At the present time there is a clause to the effect—

"That any Doctor of Medicine of any foreign or colonial university or college practising as a Physician in the United Kingdom before the 1st day of October, 1858, who shall produce certificates to the satisfaction of the Council of his having taken his degree of Doctor of Medicine after regular examination, or who shall satisfy the Council under Sections 45 and 46 of the Medical Act that there is sufficient reason for admitting him to be registered, may register the degree."

This clause, with slight modification and the omission of the date, would give the Council power to admit to the Register any diploma or degree which they might consider worthy of registration, and there is no reason why such power should not be vested in the Council.

If after due consideration the Council be willing to register certain foreign degrees, it will be better that an open clause remain, than that any particular degrees should be enumerated, for at the present time some foreign universities are vastly improving their examinations, and it must be admitted that certain cases are altered by circumstances.

The Elections at the Irish College of Surgeons.

The Fellows of the Irish College of Surgeons will meet on the 30th of May to receive from the Council the Annual Report, and will again assemble on the 5th of June to elect the Council for the ensuing year. Dr. Kidd, the present Vice-President, will, of course, assume the Presidential Chair, and Dr. Robert McDonnell will be unopposed in his candidature for the Vice-Chair. Mr. Edward Hamilton, the existing President, will seek re-election to the Council, and, if he be replaced, some one of its members who seek to hold their seats must give place. Mr. Corley, of the Richmond Hospital, is as yet the only candidate outside the Council, Mr. McDowel, of Mercer's Hospital, whose name had been mentioned, not having announced his intention to stand.

Reopening of the Children's Hospital, Chelsea.

On Saturday last, her Royal Highness Princess Louise, Marchioness of Lorne, supported by a distinguished company, formally opened the new building situated on the Chelsea Embankment of the Thames, which was commenced several months since, for the purpose of taking the place of the former private house used as a hospital since its foundation in 1866. The new structure will accommodate 65 beds, and we trust will efficiently fulfil its mission in the midst of a large and not over-wealthy population.

Charing Cross Hospital announces a vacancy on the staff as Assistant-Surgeon.

The office of Demonstrator of Anatomy at the Westminster Hospital is now vacant.

Mr. Salter, F.R.S., has been re-elected an Examiner in Dental Surgery in the Royal College of Surgeons of England.

Notice has been given that an examination of candidates for thirteen appointments as Surgeon in her Majesty's Indian Medical Service will be held in London in August next.

A prisoner in Cardiff gaol has been poisoned by the administration of a dose of carbolic acid in mistake for a diarrhœa mixture. He was shortly afterwards found insensible in his cell, and he died next day.

Dr. Hill, the Medical Officer of Health for Birmingham, reports that the water supplied to that town was turbid, with numerous particles and animalculæ. The water needs improved filtration, but there was considerable abatement in the proportion of organic nitrogen.

The *Lancet* understands that Dr. Brown-Séquard will shortly visit England for the purpose of delivering a series of lectures on the Physiological Pathology of the Brain. Dr. Brown-Séquard will enunciate entirely new views in connection with a subject on which he is known to have worked assiduously.

Dr. E. J. Mills, F.R.S., Professor of Technical Chemistry in the Andersonian University, Glasgow, reports that the water supplied to that city contained suspended vegetable hairs, and just visible particles of ochre. It was much lighter in colour than last month, and was free from all evidence of previous sewage or animal contamination.

Last week one of the inmates of the Richmond Lunatic Asylum, Dublin, threw himself out of a window, death resulting from fracture of the skull. The jury, at the inquest held, stated that the unprotected state of the window at the time of the accident was indicative of neglect on the part of some of the staff connected with the asylum.

The *Medical Times and Gazette* says: It is rumoured that a Bill will be introduced into Parliament during the present session to empower licensing bodies to admit women to examinations for their medical licences or diplomas. We have not heard, however, whether the Bill will have the support of the Government, nor whether it will attempt in any way to remove the obstacles that at present prevent female medical students from fulfilling the regulations of the English licensing bodies.

In the House of Commons, on Thursday last, a question was asked relative to filling up the vacant post of surgeon to several militia regiments. In reply thereto the Secretary for War stated that it was true that in some 35 militia regiments the posts of surgeon or assistant surgeon

were vacant owing to the appointments having been suspended pending new regulations, but it was not intended to fill up any vacancy until the militia warrant, which was now under consideration, had been confirmed. It would not be long before this took place.

THE annual *conversazione* of the Pharmaceutical Society of Great Britain was held on Thursday evening last in the South Kensington Museum. Upwards of 3,000 persons were present, amongst whom were seen many well-known faces of members of the medical profession. The arrangements were, on the whole, satisfactory, no attempt being made in the way of amusements of a special character, the majority present contenting themselves, as is usual at such gatherings, with staring at one another and getting terribly hot with the exertion.

THE *Pacific Medical Journal* says :—"They have had a 'commencement' lately in Philadelphia, at the Woman's Medical College—the oldest medical college for females, we believe, in the world. The editor of a leading Philadelphia newspaper went there to look at the wiry old maids and to enjoy a laugh at the expense of the 'ill-favoured, near-sighted, vinegar-tempered, odd-costumed, eccentric, and unfeminine' doctresses. But he played Balaam, and was so enraptured with the personal appearance and graceful demeanour and literary accomplishments of the ladies, that he applies to them the lines of Tennyson :—

> 'They sat along the forms like morning doves
> That sun their milky bosoms on the thatch—
> A beauteous range of pupils.'"

Literature.

THE MEDICAL AND SCIENTIFIC SERIALS.

THE last numbers of these publications contain an average amount of instructive and useful matter.

The *Journal of Psychological Medicine* (*a*) opens with an article from the pen of Dr. Winn, who protests against the "materialistic atheism" of Professor Tyndall, who, after having reduced soul and mind to matter, with a conspicuous inconsistency, immediately takes flight in an opposite direction, and suggests that vegetables may possibly be endowed with consciousness, and minerals with properties which are only conceded to living organisms. In a later article in the *Fortnightly Review*, Dr. Tyndall's atheistic proclivities, he says, become more apparent; for he hesitates to admit with Gassendi and Clerk Maxwell, that even the atoms were created, and remarks "that little profit to the human heart seems derivable from this mode of regarding the Divine operations." Dr. Winn concludes that he may apply to the Professor what he applies to an opponent in a note to the *Times*, on the question of spontaneous generation, for in his own case "the cloud of cosmic dust which he has raised may be safely left to the slow, sure process of self-subsidence." A second article by Mr. W. A. F. Browne, on "Deuteroscopia or Second-Sight," is well worth perusal; Dr. Semple treats of the "Pathology and Treatment of Cerebral Diseases;" Dr. Shaw, on "General Paralysis in Combination with other Diseases of the Brain;" Dr. Mann, on "Intemperance and Dipsomania as related to Insanity." The number concludes with a retrospect of subjects relating to mental pathology, reviews, &c.

(*a*) London: Ballière, Tindall, and Cox.

The Practitioner (*a*) contains original articles by Dr. Burdon Sanderson "On the Process of Fever," by Dr. Binz "On Febrifuges," by Dr. Farquharson "On Official Dosage, with some Remarks on Homœopathic Tinctures," by Dr. Faber "On the Influence of Sea Voyages on the Human Body and their Value in the Treatment of Consumption;" Clinic of the Month, Extracts from British and Foreign Journals, the Influence on the Public Health of Foul Water, &c., &c.

The Obstetrical Journal (*b*) has many important original communications, and in addition gives Reports of Hospital Practice and Abstracts of the Societies' Proceedings in London, Edinburgh, and Dublin, together with Reviews, Summaries of Cases, &c.

The Monthly Microscopical Journal (*c*) is scarcely up to the mark; it contains, however, an article of some interest to geologists—"Results of a Microscopical Study of the Belgian Plutonic Rocks," by M. A. Rénard; and "Notes on the Markings of Navicula Rhomboides," by Dr. J. J. Woodward, U. S. Army, and which clearly shows that specie-makers often jump to conclusions on very insufficient data. "The Progress of Microscopical Science" occupies a fair proportion of the number.

LITHOTOMY AND THE EXTRACTION OF STONE. (*d*)

SURGEON-MAJOR HARRIS, of H. M. Bengal Medical Service, has evidently had great experience with calculous patients, having operated on no fewer than 365 cases.

All his operations were by the knife: "Following the general custom of surgeons in India," he has not performed lithotrity (preface).

It will be a useful book of reference, for the author has given the opinions of every lithotomist of importance. Whenever he speaks from his own experience his words are worthy of attention and his advice of following. Dr. Harris's remarks and statistics (p. 240) are founded on 300 cases of lithotomy (299 left lateral operations, and 1 bilateral operation). Of these 191 were in children. As regards the children (below 16 years of age), the death ratio was, in 27·29 cases. Of the adults he lost 1 in 6·05.

Unfortunately, the notes, with the results of the remaining 64 cases, have been lost from various causes. However, as the author assures us that the statistics of them would be equally favourable with the above, we must rest content. We must congratulate the author on the success which he has obtained in his operations, and the more so as we believe he obtained it without the necessity of establishing a "special hospital."

If a second edition of the work should be called for, we would venture to suggest that it should be reduced in size by a narrowing of the too liberal margin, and by a condensation of the text.

Correspondence.

MEDICAL EDUCATION.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—I have just seen a leader in the *Lancet*, of the 6th inst. concerning medical education at the Universities. The learned editor is of opinion that it is not possible to teach clinically at Cambridge. He writes: "With regard to the Professorships of Surgery and Midwifery, if these are established, students will be encouraged to remain at the University to prosecute their studies in these branches. Can it for one moment be supposed that a town like Cambridge could furnish material for such courses. How many important operations

(*a*) London: Macmillan and Co.
(*b*) London: J. and A. Churchill.
(*c*) London: Hardwicke and Bogue.
(*d*) "Lithotomy and the Extraction of Stone." By W. Poulett Harris, M.D. London: J. and A. Churchill. 1876.

in surgery or midwifery would a student have an opportunity of witnessing during the time of study? Who is to be Professor of Medical Jurisprudence? To take rank as a University professor, he must at least have made that subject a special study," &c. Nothing is more true or sound in practice than the above extract. If such is applicable to Cambridge, (and it can hardly be held that it is not), how much more is it applicable to Galway? Galway must not be lost sight of in the discussion of such a question. It has always been a source of wonder to me how a complete medical training can be imparted in Galway. The town is not larger than Cambridge. Why then should a complete medical curriculum not be recognised when imparted at Cambridge as well as at Galway? Or if not permitted on good grounds by the former, why permit the latter? The editor referred to goes on to remark thus: "The fact is that purely medical education can only be properly carried out in London and other large centres of population," &c. I think every unprejudiced medical practitioner will admit that such is the fact, and that Galway is not the town wherein to train students for a profession which involves so much responsibility. I think it is unfair to the profession that gentlemen trained solely at Galway should be admitted by having the highest degree in medicine conferred upon them after four years' Galway training. I consider that Galway simply on account of its population is the cause of the Queen's University falling into disrepute. The professors at Galway will compare favourably with those of any other school in Ireland or elsewhere. What chair of anatomy and physiology would Cleland not adorn? It is not, unfortunately, the fault of the professorial staff.

I merely refer to the above question in order that the profession in Ireland can, if they think proper, offer their opinions on the matter, believing as I do that it is the duty of every member of our profession to contribute towards its scientific progress and develope its prestige.

I am, Sir, yours faithfully,

JOHN LOWE.

3 St. Andrew Street, Blackburn,

Medical News.

Royal College of Surgeons of England.—The following gentlemen having passed the required examination for the diploma, were duly admitted Members of the College on May 16th and 17th:—

Anderson, Charles M., Donegal.
Batchelor, Henry T., L.R.C.P., Bancroft Road.
Berridge, William A., Upholland.
Brumell, Arthur, Morpeth.
Chadwick, Walter S., Wakefield.
Clubbe, Charles P. B., Hull.
Coates, Harcourt, Salisbury.
Coley, Frederick C., Blackheath.
Cook, Joseph B., Nottingham Place.
Cooper, Peter, Farningham, Kent.
Denison, Arthur H., Sheffield.
Dinnen, William T., L.K.Q.C.P.I., Holyhead.
Drewitt, Frederick G. D., B.A. Oxon., Arundel, Sussex.
Emmerson, John B., Newcastle-on-Tyne.
Essex, James R., Pontypool, Monmouthshire.
Feltham, William P., L.S.A., Portsea, Hants.
Harrhy, William R., Tredegar.
Henwood, John D., L.S.A., Millbrook, Cornwall.
Hewett, Augustus, L.S.A., Twickenham.
Johnstone, Charles R., L.S.A., Haxey.
Jones, John D., L.R.C.P., Great Torrington.
Lee, Charles G., Chester.
Lush, John S., L.S.A., West Lavington.
Makund, Manikji D., Bombay.
Moore, Charles A., L.S.A., Thetford, Norfolk.
Morgan, William, L.S.A., Swansea.
Page, William H., Cheltenham.
Patron, Alfred, M.D. Toronto, Clapham.
Pearce, Arthur, L.S.A., Kingsbridge, Devon.
Porter, Thomas L., L.S.A., Exeter.
Robinson, George W., Faversham, Kent.
Rodwell, Edward M., L.S.A., Loddon, Norfolk.
Roughton, James W., Kettering.
Seymour, C., M.B. and M.C. Aberd., Odiham, Hants.
Stamp, William D., Honiton, Devon.
Stark, Mark D., M.B. Toronto, Toronto, Canada.
Thomas, John H., L.R.C.P. Ed., St. Ives, Cornwall.
Tyrrell, Walter, Exeter.
Upton, Alfred, L.S.A., Petworth, Sussex.
Walker, David F., Emsworth, Hants.
Welchman, Henry P., Lichfield.
Willey, John M., Leicester.
Young, Percy G., St. Stephen's Square, London.

Vital Statistics.—From the Registrar-General's return we learn that during last week 6,096 births and 3,755 deaths were registered in London, and twenty-two other large towns of the United Kingdom. The mortality from all causes was at the average rate of 24 deaths annually in every 1000 persons living. The annual death-rate was 24 per 1000 in Edinburgh, 22 in London, 28 in Glasgow, and 26 in Dublin. The annual rates of mortality during the same period in the other large towns were—Norwich 24, Hull 22, Leicester 21, Portsmouth 22, Newcastle-upon-Tyne 27, Birmingham 24, Brighton 27, Leeds 28, Wolverhampton 25, Bradford 30, Sheffield 26, Plymouth 27, Bristol 29, Oldham 28, Manchester 32, Salford 32, Nottingham 22, Sunderland 15, and Liverpool 27. The annual death-rate from the seven principal zymotic diseases averaged 3·4 per 1000 in these towns, and ranged from 0·0 and 0·6 in Norwich and Nottingham to 6·4 and 6·5 in Salford and Plymouth. The high zymotic rate in Plymouth was due to the fatality of measles, and scarlet fever continues very prevalent in Portsmouth. Ten more deaths were referred to small-pov in Manchester and Salford, within which municipalities 131 fatal cases have been recorded since 1st January last, exclusive of those occurring in the Monsall Hospital situated without the city of Manchester. In London, the 1,457 deaths included one from small-pox, 31 from scarlet fever, and 25 from different forms of fever. To the seven principal diseases of the zymotic class 199 deaths were referred, against 247, 217, and 214 in the three preceding weeks. These 199 deaths were 43 below the corrected average number from the same diseases in the corresponding week of the last ten years, and were equal to an annual rate of 3·0 per 1000.

Obituary.

DR. ANDREW WYNTER.

DR. ANDREW WYNTER, who died at the end of last week at his residence at Chiswick, at the early age of 56, was born at Bristol in 1819. He graduated M.D. in 1853, and subsequently became Member of the College of Physicians. He first became known as a writer by his "Pictures of Town from my Mental Camera" and "Pictures of Town and Country Life." He was one of the earliest and most regular contributors to *Once a Week*, under the editorship of Mr. Samuel Lucas, and he was the author of many able articles in the *Quarterly* and *Edinburgh Reviews*, and for fifteen years the editor of the *British Medical Journal*. Subsequently he contributed very extensively to the *London Review*, *Good Words*, &c. Very many, perhaps most, of his papers contributed to serial publications were reissued by him in a collective form, under the names of "Curiosities of Civilization," "Our Social Bees," "Subtle Brains and Lissom Fingers," "Curiosities of Toil," &c., which have gone through several editions. Dr. Wynter's last work was of a more strictly professional character, being a treatise on "The Borderlands of Insanity," a subject to which he had devoted much attention during the last fifteen years.

Syphilitic Reinfection.

CASPARY (*Deutsch. Med. Wochens.*, 1875, No. 7) gives three cases of syphilitic reinfection occurring two, thirteen, and four years after cure of the first attack. These afforded the usual symptoms: primary induration, universal adenitis, exanthema, &c. Caspard is inclined to regard reinfection as not infrequent, but at the same time insists upon the symptoms of universal adenitis or affections of the skin or mucous membranes in connection with the indurated sore in order to make the diagnosis positive.

NOTICES TO CORRESPONDENTS.

☞ Correspondents requiring a reply in this column are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

Reading Cases.—Cloth board cases, gilt-lettered, containing 26 strings for holding each volume of the Medical Press and Circular, can now be had at either office of this Journal, price 2s. 6d. The postal regulations not allowing the Journal to be stitched, these cases will be found very useful to keep each weekly number intact, clean, and flat, after it has passed through the post.

Testimonial to Dr. Maurice Corr, F.R.C.S.I.—The following subscriptions have been already received:—Dr. R. Battersby, £1; Dr. Benson, £1; Dr. Bennett, Clonalkilty, £2; Dr. D. F. Brady, £1; Dr. Burnside, Clondalkin, £1; Dr. Cameron, £1 1s.; Dr. Chapman, £2 2s.; Dr. Chaplin, Kildare, £1; W. Colles, Esq., £2 2s.; Dr. Darby, Bray, £2; Dr. Davys, Swords, £1; Dr. N. B. Duncan, £1; Dr. Elliott, Waterford, £5; Dr. Goodisson, Enniscorthy, £1; Dr. Harvey, Cork, £1; Dr. Hayden, £3 3s.; Rev. Prof. Haughton, £1; Dr. Kidd, £5; Dr. J. Little, £3; Dr. Mapother, £5; Dr. Martin, Portlaw, £1; Dr. M'Gusty, Slane, 10s.; Dr. Mollan, £2; Dr. Nicholls, Longford, £1; Dr. Nolan, Gort, £1 1s.; Dr. T. H. Purdon, Belfast, £10; Dr. Shannon, £2 2s.; Dr. Shaw, Lurgan, £1; Dr. Smith, Ballybrophy, £1 1s.; Dr. Wharton, £2 2s.; W. I. Wheeler, Esq., £5. The following gentlemen have kindly agreed to act on the Committee and receive further subscriptions, which are urgently needed:—Dr. C. Benson; Dr. Chaplin, Kildare; Dr. Chapman; W. Colles, Esq.; Dr. Darby, Bray; Dr. Harvey, Cork; Rev. Prof. Haughton, T.C.D.; Dr. Hayden; Dr. James Little; Dr. Martin, Portlaw; Dr. Nolan, Gort; Dr. O'Leary, M.P.; Dr. T. H. Purdon, Belfast; Dr. Smith, Ballybrophy; J. H. Wharton, Esq.; W. I. Wheeler, Esq.; Dr. Mapother, 6 Merrion Square North, Hon. Sec. and Treasurer.

Examination in State Medicine at Cambridge.—We are asked to announce that the next Examination for Certificates in Sanitary Science will be held in Part I. on Tuesday and Wednesday, June 13 and 14, and in Part II. on Thursday and Friday, June 15 and 16. Candidates must send their names and fees to Professor Liveing, Cambridge, on or before Tuesday, May 30. Any one whose name is on the Medical Register of the United Kingdom and is 24 years of age may be a candidate.

Dr. Dolan.—We shall refer to the subject in our next.

Mr. R. E. T., Falmouth.—Letter received, but not the enclosure to which you refer.

Dr. B. F. will find the subject of his communication referred to in another column.

Dr. West is thanked.

Dr. Austen Meldon.—There are several institutions of the kind in both France and Belgium; we will make inquiries and inform you of the best in our next issue.

Clinical Society of London.—The following is the programme for Friday evening next:—Mr. Barwell: Singular Result of Excision of the Knee in a Child (the Patient will be exhibited).—Mr. Geo. Brown, "On a Case of Amputation of the Thigh for Acute Necrosis of the Tibia and Suppuration of the Knee-joint in an Infant nine months old" (the Patient will be exhibited).—Dr. Duffin, "On a Case of Tumour of the Corpora Quadrigemina."—Dr. Pearson Irvine, "On a Case of Diphtheritic Paralysis simulating Extensive Lung Disease."—Mr. Teevan, "On a Case of Traumatic Stricture with numerous Fistulæ Cured by Internal Urethrotomy."—Dr. Wolston and Mr. Maunder, "On a Case of Intestinal Obstruction."

THE TEMPERANCE MOVEMENT.

To the Editor of the Medical Press and Circular.

Sir,—I was not surprised to see the kind notice, in your last issue, of the intended political-temperance meeting in Hyde Park on Whit Monday, knowing as I do from pleasureable experience, the active benevolence which distinguishes the medical profession, and their continued efforts for the amelioration of human suffering and woe. I should be glad, however, if you would allow me to state, for the information of those of your readers who may not have yet become acquainted with the fact, that the demonstration promises to be of such vast proportions that the persons who originally conceived the idea are as gratified as they are surprised at the extraordinary support they have met with in all directions from gentlemen holding high social positions—members of Parliament, large numbers of the clergy, and medical gentlemen—who have promised to be present at the demonstration. There are to be four platforms in the Park, from which resolutions will be proposed, in accordance with the object we have in view—namely, the suppression of drunkenness, and the consequent elevation of all classes. Amongst those friends who will take part in the proceedings are Sir W. Lawson, Joseph Cowen, Esq., M.P., A. M. Sullivan, Esq., M.P., Alderman Carter, Samuel Pope, Esq., Lord F. G. Osborne, Rev. W. Lockhart, &c., &c. I am sure your noble profession will be pleased to know that the cause of temperance is so well supported, and that such good friends are coming to the front to assist the working classes in their endeavours to rid the country of the terrible mischief caused by the unlimited traffic in, and use of, strong drink.

I am, Sir,
Yours faithfully,
58 Poland Street, W. H. P. Gibson.

VACANCIES.

Charing Cross Hospital.—Assistant-Surgeon. Honorary. Must hold the F.R.C.S.E. diploma. Applicants must address the Secretary.

Bristol Royal Infirmary.—Assistant House-Surgeon. Salary, £100, with board. Address the Secretary.

Brighton Hospital for Sick Children.—Surgeon. Honorary. Full information from the Resident Surgeon.

Northampton County Lunatic Asylum.—Assistant Medical Officer. Salary, £120, with board. Applications to the Medical Superintendent.

Bournemouth General Dispensary.—House-Surgeon. Salary, £120. Testimonials to R. T. Hearn, Esq., at the Dispensary.

Ashton-under-Lyne Infirmary.—House-Surgeon. Salary, £80, with board. Testimonials to Mr. Hugh Mason, Ashton-under-Lyne.

Ipswich Lunatic Asylum.—Assistant Medical Officer. Salary, £100, with board, &c. Address the Medical Superintendent.

Westminster Hospital Medical School.—Demonstrator of Anatomy. Salary, £75. Address the Dean.

Knighton Union.—Medical Officer for the Leanbister District. Salary, £100, with fees extra. Testimonials, &c., to the Clerk to the Guardians.

Newport Union, Achill Dispensary District.—Medical Officer. Salary £100, with £10 extra as Sanitary Officer. (See Advt.)

APPOINTMENTS.

Atkinson, G. F., a House-Physician to the Glasgow Royal Infirmary.

Ballard, W. W., M.D., M.R.C.S.E., a Medical Officer to the County Hospital, Huntingdon.

Briggs, W. P., a House-Surgeon to the Glasgow Royal Infirmary.

Curran, J. W., F.R.C.S.Ed., L.R.C.S.I., L.K.Q.C.P.I., reappointed Medical Officer and Public Vaccinator for No. 2 District of the Mansfield Union.

Drew, S., M.D., L.R.C.S.Ed., Lecturer on State Medicine at the Sheffield School of Medicine.

Dunn, W. G., a House-Physician to the Glasgow Royal Infirmary.

Elliott, W. H., M.D., L.R.C.S.I. & L.M., Medical Officer, &c., for the Glendermott Dispensary District of the Londonderry Union.

Grahame, A., a House-Surgeon to the Glasgow Royal Infirmary.

Hemming, J. H., M.R.C.S.E., Medical Officer for the D District of the Thrapston Union.

McKenna, W., L.R.C.P.Ed., L.R.C.S.I., Medical Officer to the Carrickmacross Union Workhouse.

Macpherson, R. B., a House-Physician to the Glasgow Royal Infirmary.

Moyes, J., a House-Surgeon to the Glasgow Royal Infirmary.

O'Meara, M. A., L.R.C.S.I., L.K.Q.C.P.I., Medical Officer, &c., for the Piltown Dispensary District of the Carrick-on-Suir Union, co. Tipperary.

Orr, A. B. S., a House-Physician to the Glasgow Royal Infirmary.

Pinkerton, R., a House-Surgeon to the Glasgow Royal Infirmary.

Rose, W., Assistant-Surgeon to King's College Hospital.

Shearer, J., M.A., House-Physician to the Aberdeen Royal Infirmary.

Stone, G., L.R.C.S.Ed., L.R.C.P.Ed., House-Surgeon to the Liverpool Eye and Ear Infirmary.

Thompson, J. A., Physician to the Artists' Amicable Fund.

Tindall, D., a House-Surgeon to the Glasgow Royal Infirmary.

Townsend, C. P. G., L.R.C.S.Ed., Assistant Medical Officer to the Hospital for the Insane, Barnwood, near Gloucester.

Trail, G. S., M.A. House-Surgeon to the Aberdeen Royal Infirmary.

Tuke, J. H., M.R.C.S.E., Medical Officer for the South District of the Stratton Union, Cornwall, and Medical Officer of Health for the South Sub-District of the Stratton Rural Sanitary District.

Turner, F. J., L.R.C.P., a House-Physician to the Glasgow Royal Infirmary.

Marriage.

Duffin—Brennan.—On the 16th inst., at the Presbyterian Church, Belfast, Adam, eldest son of Charles Duffin, J.P., of Strandtown Lodge, county Down, to Maria, eldest daughter of John S. Brennan, M.D., Belfast.

Deaths.

Coleman.—On the 7th May, at Surbiton, Kingston-on-Thames, Matthew Trollope Coleman, M.R.C.S., aged 64.

Cooper.—On the 12th May, at Mansfield, Notts, Nathan Cooper, M.R.C.S.E., aged 72.

Duncan.—On the 13th May, at Bognor, James Duncan, youngest son of Robert Duncan, M.D., Hanover House, Tunbridge Wells.

Joy.—On the 9th May, at Seymour Street, Hyde Park, John Joy, M.R.C.S.E., aged 65.

Kerin.—On the 4th May, at Windsor, F. G. Kerin, L.R.C.S.I., Surgeon-Major 2nd Life Guards, aged 49.

Leigh.—On the 8th May, at Brighton, Henry Thomas Leigh, F.R.C.S.E., of Chiswick, aged 69.

Rendle.—On the 15th May, at 6 Buckland Terrace, Plymouth, Edmund Rendle, M.D., in his 76th year.

Thatcher.—On the 5th May, at Albany Street, Edinburgh, Lewis Hay Thatcher, M.D.

UNIVERSITY OF LONDON.

NOTICE IS HEREBY GIVEN, that the next Half-yearly Examination for MATRICULATION in this University will commence on MONDAY, the 26th of June, 1876. In addition to the Metropolitan Examination, Provincial Examinations will be held at St. Cuthbert's College, Ushaw; Stonyhurst College; St. Stanislaus College, Tullamore; Owens College, Manchester; Queen's College, Liverpool; and Queen's College, Birmingham.

Every Candidate is required to transmit his Certificate of Age to the Registrar (University of London, Burlington Gardens, London, W.) at least fourteen days before the commencement of the Examination.

WILLIAM B. CARPENTER, M.D.,
May 22nd, 1876. Registrar.

OWENS COLLEGE MEDICAL SCHOOL.—The Council of Owens College, Manchester, propose to appoint a LECTURER in PRACTICAL SURGERY. Candidates are requested to send in applications and testimonials, addressed to the Council, under cover to the Registrar not later than June 17th. Information respecting the duties and emoluments of the office may be obtained from Dr. Gamgee, Dean of the Medical School.

J. HOLME NICHOLSON, Registrar.

IRISH POOR-LAW INTELLIGENCE.

ATHY UNION.

CONSULTATION FEES IN MIDWIFERY.

THE relieving officer of the Athy district reported that Dr. Ferris, the dispensary medical officer, found it necessary to call in the assistance of Dr. O'Neill recently in a very serious case, and he (the relieving officer) had set down the fee charged (two guineas) as provisional relief.

In reply to some of the guardians, Mr. O'Brien said it was clearly in the power of the relieving officer to do so. If the guardians objected, the only course open to them was to call the attention of the auditor to the matter, and if he considered it an unwise discretionary act, he could surcharge the relieving officer with the amount.

Mr. Dunne called the attention of the guardians to a case that came beford the board recently, where a medical officer charged three guineas. The only objection he had to the present case was that the sum charged was too small.

ABUSE OF DISPENSARY RELIEF.

(From the *Sligo Independent.*)

ALDERMAN M'GILL, as honorary secretary to the Sligo Dispensary Committee of Management, has received from the Local Government Board a communication, relative to the abuse of dispensary tickets, which we give below. It is to be regretted that there appears to be no remedy for a very great grievance. The law does not specify who a "poor" person is, and those who are far from being poor, can get the gratuitous attendance of an overworked dispensary doctor, and can get expensive medicines at the expense of the ratepayers. However, as the law does not apply a remedy, a little care and attention on the part of the members of a dispensary committee, wardens, and relieving officers, would do much to lessen, if not do away with the abuse. They should strictly confine the giving of tickets to those they know to be really poor. The wholesale and indiscriminate filling up of dispensary tickets should be avoided, and those who can pay a doctor should be made to pay one. It is, indeed, lamentable that people with good means, and earning regular good wages, should be found accepting of medicines and medical advice as alms, for it is nothing else. The dispensary committee, too, by a careful inspection of the books at each meeting, can easily detect if the abuse is being carried on, and can check its further development. The Medical Charities Act brought a great boon home to those who are really poor, but it would have a demoralising effect if comfortable farmers and well-paid artisans, or those who had a good way of living could come within its scope. The operations of the Act are expensive, and it behoves dispensary committees to see that a serious abuse of this sort does not swell the cost. The following is a copy of the letter received by Mr. M'Gill :—

Local Government Board, Dublin,
9th May, 1876.

SIR,—The Local Government Board for Ireland acknowledge the receipt of your letter of the 28th ultimo, enclosing a resolution adopted at the meeting of the Committee of Management of the Sligo dispensary district on that day, in which the committee state that it has been brought under their notice that persons have obtained medical relief tickets who are not entitled to medical relief, and inquire what course should be pursued to check the abuse; and, in reply, the Board desire to state that there is no strict definition of the classes eligible or ineligible for medical relief under the provisions of the Medical Charities Act, 14 and 15 Vic., cap. 68.

By section 9 of that Act every member of a committee of management of a dispensary district, and every relieving officer and warden acting for an electoral division included in such dispensary district, is empowered to issue medical relief tickets to the medical officer of such district, requiring him to afford medicine and advice to, or attend upon, any "poor person" resident therein.

The Local Government Board have to add that they are not prepared, in the present state of the law, to suggest any remedy for the abuse of this privilege; but the regular meeting of the dispensary committee for the discharge of their duties would, no doubt, tend to lessen its occurrence.

By order of the Board,
B. BANKS, Secretary.

["A most lame and impotent conclusion," truly, and one which looks more like an unwillingness on the part of the Local Government Board to discourage the abuse of red tickets than a simple feebleness of purpose. The Local Government Board could, if they pleased, do much toward putting a stop to these abuses without altering the law, and it is their duty to do so for the benefit of the ratepayers, if not for the doctors. If they can suggest no better remedy than a more frequent meeting of the committee, it is hard to expect the committee themselves to combat the evil.—ED. M. P. & C.]

WORKHOUSE DIET IN IRELAND.

THE public must be astounded to learn that since the outbreak of the famine in 1846, a period of thirty years, no material change for the better has taken place in the scale of the dietary of the Irish workhouses. The scale was fixed when the Government and the Irish landlords were apprehensive that the assumed proneness of the lower classes to idleness and mendicancy, stimulated by pressure of the famine, would cause such enormous taxation for the relief of destitution as would confiscate nearly the whole real property of the country. The scantiness of the diet was therefore intended to serve as a deterrent. Framed in total ignorance of the true character of the people the scale has been maintained ever since, notwith-

standing the falsification of the apprehensions that inspired it, and in face of the vast social and economic changes that supervened. There are many times more paupers in receipt of relief compared with the population in England and Scotland than in Ireland, while some of the Irish workhouses often do not contain more than two or three score of inmates, not one of whom is able-bodied, and the majority of whom are aged or infirm, or children. These considerations should weigh powerfully with the Local Government Board and the guardians towards the reform on a liberal basis of the scanty scale of dietary settled in 1846, and never since improved. There are, however, other and very strong reasons in favour of this course. The scale of diet for paupers in a workhouse ought to a great extent to be framed in accordance, as to quantity, quality, and articles, with the habits and means of the humblest class of persons next above the paupers; but rather higher and more generous, however, as experience proves that workhouses, prisons, barracks, and all such institutions demand a more liberal scale of food for inmates of like age to maintain their health than private families. So far from this relation being regarded and preserved, the prison dietary in Ireland is much more generous than that of the workhouses, so that actual temptation is held out to a destitute poor person to become a criminal, and thereby obtain a more generous scale of dietary. Next, and a most important consideration, while the food and clothing of the labouring classes have improved vastly in quantity and quality since the present scale of workhouse dietary was fixed thirty years ago, no corresponding nor any improved change has been made in the latter. On medical, humane, and economical grounds, a generous diet should be adopted now, to which thirty years ago prudential objections might be made. The small element of pauperism now in Ireland is happily so contracted that it may be generously dealt with free from abuse. Consumption and diseases of the respiratory organs are peculiarly common and fatal in Ireland, and most so among the poorer and the destitute classes. If the children in the workhouses be not generously fed and warmly clothed, most of them will sink at an early age, or become the progenitors of successive races of sickly paupers.

BELFAST UNION—A WORKHOUSE GROG-SHOP.

At the last meeting of the Belfast Union the following transpired:—

The Chairman read a letter from Miss Mary Killen, nurse in the hospital, resigning the situation which she had now held for several years, but at the same time it was reported by the master that an inmate named M'Cann, and who was at present in charge of the lunatics as warder, had been found a few days ago with a small bottle of whiskey in his pocket, and that he stated he had purchased it from Miss Killen.

M'Cann was then sent for, and stated that he bought the half-pint of whiskey from Miss Killen.

The Chairman—How did you know she had it? I understood I would get it there. How did you know it? It was generally known in the house, and I knew that I could get it there.

Have you heard for some time that this woman was selling whiskey? I could not exactly say, but I heard it for some time from about a month ago.

How often did you buy whiskey from her before? This was the second time.

And who gave you the money to buy it? (No answer.)

The witness, after hesitating, said a young man and he joined, each giving 7d. to buy the half-pint.

Mr. Watt (master) here brought forward a sample of the whiskey kept in the house, and several of the guardians expressed themselves satisfied that both samples were not the same whiskey.

The Chairman, questioning M'Cann, further asked how often he bought whiskey from Mary Killen before? He said he bought it twice—once for James Salmon, and the other for Mary M'Kee.

James Salmon was next called forward. He said he was one of the two warders in charge of the lunatics. He admitted having sent for the whiskey with M'Cann.

Did you ever hear of whiskey being sold in this house? Yes, I heard it was sold in the hospital at different times.

How long have you been in the house? About ten months.

Who did you hear was selling it? I heard that Miss Killen was selling it.

Did you ever join with this person before in sending for whiskey. Yes; once or twice.

Miss Killen, in reply to the Chairman, said she had no questions to ask any of the men.

Mr. Clegg—Then you sold him the whisky? No, I did not; I gave it to him.

Dr. Strahan, in reply to the Chairman, said he had frequently heard rumours in the house that this was going on.

Chairman—And did you not tell the Master? I did not, because he saw that it was a general talk through the house.

The Chairman—What did you hear? I heard popular rumour through the house that there was whiskey being sold in it to the inmates.

The Master (Mr. Watt) said that some six months ago he consulted Dr. Reid on this subject, and he tried to gain every information that he could.

Mr. Ward—I don't think the board ought, under the circumstances, to accept Miss Killen's resignation, and I would beg to move her dismissal.

Mr. Clegg—I beg to second that.

The motion was passed unanimously.

Mr. Clegg—I now beg to move the discharge of all the inmates who were connected with the buying of this whiskey.

The motion was passed.

KILLESHANDRA DISPENSARY DISTRICT.

Mr. Duignan handed in a letter from Dr. Brown, resigning his office as *locum tenens* of Dr. Kenny, the medical officer of the Killeshandra dispensary district. It appears that Dr. Kenny has been indisposed for sometime and that the duties were performed by his son; but the younger Dr. Kenny having recently had his leg broken, the dispensary committee appointed Dr. Brown *locum tenens* at a salary of £3 per week. When the appointment came before the board of guardians on the 25th ult., it gave rise to considerable discussion, many of the guardians expressing themselves opposed to the scale of remuneration fixed by committee. Mr. Telfor moved that Dr. Brown be paid at the rate of half Dr. Kenny's salary (£50), which was seconded by Mr. Martin. An amendment was proposed to the effect that he receive as a remuneration an amount equal to Dr. Kenny's full salary (£100). A rider was proposed that Dr. Kenny pay his own *locum tenens*.

On a division there voted—

For the rider	...	...	7
For amendment	...	...	5
For original motion	...	...	2

The rider was thus carried by a majority of 2 over the amendment and 5 over the original motion.

Mr. Duignan wished to know how the committee were now to act, as the district was vacant in consequence of Dr. Brown's resignation.

The Board decided that it was the duty of the committee under the above circumstances to call an extraordinary meeting and appoint a properly qualified person to the office.

[Any medical officer who places himself at the mercy of such persons as these guardians has himself to blame if he is treated as they have treated Dr. Kenny. The medical officer has no occasion to give himself the least

trouble or undergo the least responsibility in the matter. It is his business only to notify his incapacity for duty to his committee secretary, and leave the committee and guardians to get out of the difficulty any way they please. If the medical officer takes upon himself the liability of bargaining with a *locum tenens* or nominating one he will leave both himself and the substitute open to be "done" by the guardians, and he is quite sure to get no thanks for his anxiety about it.]

REPORT OF THE INSPECTORS
ON THE
LUNATIC ASYLUMS IN IRELAND.
(*Continued.*)

We are gratified to report that during the past twelvemonths no tangible causes of complaint have been submitted to us either personally or by letter from any patient, neither have we been officially communicated with in regard to alleged grievances or unkind conduct towards the insane resident in private licensed establishments by their friends; in fact, dissatisfaction finds an expression much more from the confined, and, we regret to add, in some cases with justice, at the inattention and neglect of near relatives, who seem indifferent to them when social family intercourse has been broken by mental disease.

To such complainants the visits of the Inspectors are simply a consolation.

No escape or casualty occurred during the year, but unfortunately two suicides were effected—the first at Hampstead House, one of the best regulated of the private Asylums. A gentleman destroyed himself by strangulation; his dangerous tendency was well known, and it was thought every reasonable precaution had been taken. Two attendants were in special charge of him, one by day the other by night, but he momentarily eluded their vigilance, concealed a handkerchief, with which he effected his purpose in bed. A coroner's inquest was duly held, at which some very near relatives of the deceased and an Inspector attended. After a long and searching investigation, a verdict exonerating the proprietors of all blame was returned. The second took plaae at St. Vincent's; a lady who for many years had been resident in the institution, quiet and amenable at all times, and who was never suspected of a suicidal tendency, took away her own life by hanging. A coroner's jury acquitted the attendants of negligence.

We have to record no variation either in the number of private Asylumns or in their management; as observed by us in a previous report, some in a social point of view, and from the more liberal payments required for care and maintenance, are conducted in a very superior manner to others, and with every regard to social comforts and suitable enjoyment. When, however, deficiencies are noticeable, we do not fail to point out the expediency of meeting them. In regard to dietary, a regular and daily scale, showing the amount and variation, has been lately obtained by us; our object in procuring it was to have a condition to inquire the better into any dissatisfaction that might be expressed in regard to it at our different visitations.

The four mixed institutions for paying and free patients—St. Patrick's, or Swift's Hospital; Bloomfield Retreat, belonging to the Society of Friends; and St. Vincent's, for ladies only, under the immediate superintendence of a religious community, the Sisters of Mercy, continue to be efficiently managed in every detail.

Central Asylum, Dundrum.—The accommodation in the Central Criminal Asylum is adapted to 185 patients, in the proportion of 120 beds for males and 65 for females. On the 31st December, 1873, there was a total of 160 in the house—121 of the former, 39 of the latter sex. During the subsequent twelvemonth 13 were admitted—11 men and 2 women—while within the same period the discharges amounted to 9—2 males recovered, 2 improved, 1 incurable, and 2 females improved, 2 incurable. The deaths, 5—3 of men, and 2 of women, with 1 male escape, diminished the full number under treatment by 15: thus leaving on the 31st December last 123 males and 25 females in confinement, or 2 less than at the close of 1873. With regard to age—of the 158, 49 were over 50, and to social condition, 32 only were married, and 126 unmarried, the illiterate of both, or those who could neither read nor write amounted to 63; thus the illiterate criminal lanatics, judging from the general statistics at our command, would appear to be proportionately three times more numerous than the patients in District Asylums. Further criminal propensities among the insane according to the above date seems to be more developed in males and the unmarried, than in females and the married classes.

Analysing the mental state of the resident in Dundrum, 22 may be considered sane, and the remaining 136, with the exception of 4 males, incurable. The category of offences comprises 64 homicides, 16 violent and 24 common assaults, 6 burglaries, 5 cases of arson, with 42 minor infractions of law, but for the most part by individuals of a passionate or vindictive disposition. The escape referred to was effected by a prisoner acquitted of homicide on the plea of insanity, who was of sound mind all through in the Asylum, and as far as is known has emigrated to America.

The admissions, thirteen only during the year, taking into consideration the excitable character of the lunatic population in Ireland, were certainly very limited in number. Still we believe few as they have been that the discretion exercised by us and a strict examination into the merits of each of the cases submitted from transference from convict prisons, or more directly from gaols subsequent to trial at assizes or quarter sessions, have been attended with no local injustice or inconvenience. Were all lunatics charged with misdemeanours in this country to be immured in a criminal asylum and detained therein for indefinite periods, we should probably have an annual influx of some five and thirty individuals, necessitating a continual increase of buildings and a longer confinement than in ordinary institutions for the insane. Regarding the establishment at Dundrum as primarily designed for persons who are supposed to lose their reason when undergoing penal servitude, and some of them it must be added are for a time accomplished malingerers, or for persons who while insane committed grave offences or even minor ones, but with the exhibition of malignant feelings, as a rule we restrict admissions to them alone; bearing further in mind that not unfrequently the charge against a lunatic is merely symptomatic of his malady, as when in a moment of excitement he injures through inadvertence property not his own, attempts personal violence, or is instigated to criminal acts by designing persons, as in the case of a man indicted for breaking farm gates and the robbery of cattle which at night he was found driving along the high road to market, the true culprit following at a distance.

The discharges during the year amounted to 9—2 recovered, 4 improved, and 3 incurable, which were thus disposed of—4 females and 2 males were transferred to district asylums, and 3 males removed by their friends, all having terminated the legal periods of imprisonment.

The mortality, and in each case, from natural causes was limited to three males and two females advanced in life, being as nearly as possible at the rate of three per cent. No casualty of any kind occurred in the institution save one, a dislocation of the elbow-joint in a refractory patient from a fall, when being borne by the attendant nurses to a padded cell. Devoid of all prison-like appurtenances as the buildings, airing courts, and grounds can be truly represented, no personal violence has been committed by any of the patients on their companions, or injury done to property, furniture, or the interior ornamentation of the house.

The large number of patients of both sexes daily employed during the year presents a strong indication of good management at the Dundrum Asylum; 85 men,

between trades, out-door, and miscellaneous occupations, and 25 women at domestic work, show to what useful purposes the time of the insane can be converted.

The stock and cultivation of the farm, twenty-eight acres in extent, incurred an outlay of £699 12s. 10d. The return for which sum reached £930 4s. 2d., thus accounted for—£104 19s. 6d. was received and paid into bank, for produce sold, £825 4s. 8d., being the estimated value of produce consumed at current market prices, leaving a profit as vouched and transmitted in detail to the audit commissioners £240 11s. 4d.

The total monetary receipts from the Treasury for the maintenance of an average per day during the year of 154 patients, including salaries and allowances of officers, wages of servants and attendants, their clothing, sustenance, &c., land and garden expenses amounted to £5,286 6s. 5d., with a balance in hands of £323 19s. 4d., constituting a capitation cost for the twelvemonth of £35 14s. 7d. The items not accounted for by us in the above general expenditure were fuel and washing materials supplied by the Board of Works; as also superannuation pensions which, after twenty-four years of occupation, did not exceed £108 6s.

Independent of remunerative employments, the inmates of the Dundrum Asylum are fairly supplied with other and more agreeable means of occupation within and out of doors as may be suited to their taste—athletic games, cards, drafts, music, periodicals, papers, &c. The interior of the institution with a strict regard to cleanliness, order, and ventilation, in the various corridors, dayrooms, dormitories associated and single, while the pleasure grounds opposite the front buildings are ornamentally arranged and planted; thus though the epithet of criminal attaches to the name of lunatics there, a benevolent attention to their wants and comforts is liberally accorded, still the yearning for freedom is not the less urgent among the convalescent or those who recognise their position. The malingerer after a time gets tired of his condition, the conversation, and monotonous language of his associates. The female convicts whose principal title to insanity is not unfrequently referrable to insubordination, virulence, and an utter disregard to rule and propriety of conduct when in prison, seek a return to penal confinement with promises of good behaviour if the favour be granted, sent back, the same violence and contumacy, which no discipline or punishment can repress, are repeated, to end in the same result, a medical certificate of lunacy. Notwithstanding the antecedent character of many of the inmates of the Dundrum Asylum, as a body they are remarkably quiet and well-disposed, fully as much as in ordinary institutions, living in harmony among themselves. Any cause of complaint is immediately referred to the Inspectors for adjudication by the Resident Medical Superintendent and Governor who exercises great vigilance over the well-being and interest of the institution professionally and fiscally.

THE GENERAL COUNCIL OF MEDICAL EDUCATION AND REGISTRATION.

WEDNESDAY, MAY 24TH.

Mr. Lister, Dr. Pitman, Mr. Simon, and Mr. Teale were introduced as the new members of the Council in place of Dr. Begbie, Dr. Bennett, Dr. Parkes, and Dr. Sharpey. The President then delivered the following Address :—

The Medical Council meets once more, deprived of four of the members who shared last year its deliberations. Dr. Bennett, as President of the College of Physicians of England, removes his clear calm judgment and assiduous services to another and kindred sphere. The persuasive speech and large knowledge of Dr. Sharpey will be longed missed by the Council. Feelings of hearty regard will linger round the earned repose of this nestor of biological science. Of Begbie and Parkes I can scarcely speak. Any formal obituary notice would be out of place here. Yet may it be said, that Dr. Begbie was already endeared to us all, having won at once by his gracious presence that esteem which all Scotland had long bestowed. The Council would probably hold any words from the President concerning Dr. Parkes to be inadequate. His purity of heart, his self-sacrifice, his courage, his grasp of details, were beyond praise. Whenever his powers were brought to bear on our work (and when were they not?) we felt them to be the powers of a strong man, whose strength was surpassed by his generosity, his gentleness, and his goodness. Whilst regretting these great losses, we cannot but feel that the interests of the science and practice of our profession, the care of the public health, the progress of medical education in its complex relations, will be honourably and efficiently considered by those now appointed to succeed them. Although the work of the Council lies strictly within the Act of 1858, it nevertheless increases as time goes on. The Council closely holds to the function of securing a sound education for those who have to do with individual or with national health. But the whole question of national education has shifted within the last twenty years, and the relation of the public to the medical profession in respect of scientific knowledge has altered also. When Mr. Walpole's bill of 1858 was passed, the corporations of physicians, of surgeons, and of apothecaries were still generally accounted in England the chief promoters of biological learning. Now, universities and society at large are not less its promoters and guardians. In literary serials and in common society abstruse questions on all the physical sciences, and notably on biology, are freely discussed in a way which fifty years ago very few persons even in the medical profession could have followed. Psychological problems find data formerly unexpected in minute physical inquiries into development, inheritance, and pathology, ranging through the animal series of every epoch of the globe. It is not then surprising that the topics which the Council has to consider little favour a supposition once entertained and last year alluded to, viz, that its work would be almost ended when all the licensing bodies had been visited by inspectors, and their reports had been received. It would be nearer the truth to say that when once the whole Council was satisfied that it could implicitly rely on the uniformity of a minimum standard in all the examinations, then there would be leisure calmly to study in detail the exact value of that standard, and of the education which was to be tested by it. The Council would then be in a position to take a broad view of the relation in which the medical student of our day stands to modern wants, modern science, and modern division of professional labour. The Council has had once and again to do this in a general manner; but the many undiscussed reports before us may satisfy us what a mass of unsolved detail remains. Dr. Farr, the eminent statistician, at the beginning of the year drew my attention to a statement in the Supplement to the 35 th Report of the Registrar-General. (*a*) He says there that in the army there is a surgeon to every 202 men; in the general population 1 to every 1276 of the population. The proportion of medical

(*a*) "Supplement to Report of Registrar-General," p. lxxxii.

men was in 1851 9·7 to every 10,000 living, 8·3 in 1861, and only 7·8 in 1871. In the army 49 per 10,000 are required. It has become a matter of public concern that it is difficult to supply the vacancies in the army medical staff with competent practitioners. Dr. Farr further writes to me, "One thing is certain, that the medical attendance for the people of England was extremely defective in 1851, and that it is still more defective in 1876. The danger is that it may grow quite inaccessible to vast numbers of the people. We know how this arises. Every one in the profession wishes to see every man in it instructed up to the highest standard." It appears from Dr. Burke that in Ireland the proportion of medical men seems to have increased from about 4 to each 10,000 in 1851 to 5 per 10,000 in 1861, and 6 per 10,000 in 1871. But Mr. Pitt Dundas states that in Scotland the number has diminished as in England. There were 7·2 per 10,000 in 1851, 6·1 per 10,000 in 1861, and 5·2 per 10,000 in 1871. (*a*) Should it appear on investigation that the supply of medical men is inadequate, and that the poorer classes especially are attended by unregistered practitioners, it may become a proper subject for inquiry by the Council whether there is any ground for supposing the examinations to be undesirably deterrent, or the methods of preparing for them in any special manner inadequate, or whether there are any details of study enforced, which have no direct relation with the clinical practice of their profession, and of which the average student's memory may be lightened, or whether the secondary schools which our students attend do indeed give the best preparation for the medical life, whatever that may be. This subject has an important bearing on the question which is more and more forced upon the Council, how to ensure such a test of a sound minimum education in each branch of the kingdom, as can be relied upon not so much for its severity as for its wisdom, and which we may feel sure is the fittest preparation for actual practice and daily life. It will appear presently that a sharp debate may spring up on this matter from an unexpected quarter. It may be well here briefly to refer to subjects brought before your executive committee since the last meeting. These have been few, but neither unimportant nor unsuggestive.

First, as to Registration of Death Certificates.—Representations have been again made with regard to the signing of death certificates by unqualified practitioners, or by qualified practitioners in cases where they have never seen the deceased. (*b*) The Registrar-General has written fully on the subject in letters (*c*) which appear in the minutes of the executive committee. It will be a public benefit if this often-raised question brings about a uniform and satisfactory mode of certifying to the causes of death in the three branches of the kingdom. The Registrar-General is entitled to the thanks of the Council for his uniform and courteous attention to a question, often repeated, because in its very nature difficult of settlement in both dense and thin populations. An apt illustration of this is found in the weekly return of births and deaths in London for the 13th of May. "During the three weeks ending the 6th instant the causes of no less than 13 per cent. of the deaths registered in Peckham were uncertified either by registered medical practitioner or by coroner. This unsatisfactory condition of the death-register is mainly due to the employment of unqualified assistants by medical practitioners in that neighbourhood. When patients are exclusively attended by unqualified assistants, no legal certificate of the cause of death can be obtained unless an inquest be held."

Second, as to Proficiency in Vaccination.—A case of some importance should be named to the Council, though a further statement will come from a committee. A practitioner in Essex was refused an appointment under the Local Government Board in the district where he lived on the ground that his certificates were not in conformity with the regulations of the board, as regards the knowledge of vaccination. Such a refusal, besides causing inconvenience, would tend greatly to his discredit. He had complied, as he believed, with all that had been required by the Medical Council and the College of Physicians, and had the testamur which the college recognised. It was ascertained that this was not a solitary case, and as it was one calculated to inflict real hardship on innocent students no time was lost in obtaining the fullest information on the causes of the occurrence. That information has been laid before the executive committee, and before the Branch Council of England, and committess have been appointed to report on the whole subject. It had been hitherto supposed to have been finally adjusted by the careful discussions in the Council in the years 1867 and 1868. (*a*) It is to be hoped that such regulations will hereafter exist that both the efficacy of vaccination and the character of the younger practitioners may be alike secured. We may pass to subjects brought before the legislature since you separated. The attention of the government was drawn to the state of the conjoint scheme in England by a question put in the House of Commons on March 9, 1876, to the vice-president of the Privy Council. Lord Sandon's reply was that, "The government has reason to believe that as regards England considerable progress has been made towards settling the basis of an arrangement which is likely to receive general assent. We have not the like information respecting Ireland and Scotland; but if satisfactory arrangements are concluded in England, I cannot but hope that they will lead to a like result in the other parts of the United Kingdom. In this state of the case I cannot give any opinion as to what may be the views hereafter of her Majesty's government as to the expediency or necessity of proposing legislative measures to promote or hasten the general adoption of the conjoint scheme." It is possible that at a later period of our meeting the matter may be more fully gone into. At present it stands broadly thus: After thirty-nine meetings at the College of Physicians a scheme for England was agreed upon in 1874 by all the bodies in England except the Apothecaries' Society, and was accepted by the Medical Council. In the course of last year, before it could come into operation, this approved scheme was rediscussed at the instance of the Royal College of Surgeons of England. Another scheme was agreed to, after seven meetings, by a majority of the representatives of every licensing body in England. It must be a matter of regret to Sir James Paget, the assiduous chairman at these conferences, that all the bodies represented have not confirmed the conclusions of the majority of the delegates. The only scheme now before the Council is that of 1874, which is not cancelled; but, also, it is not in operation. There is therefore no motion on the subject before the Council; and there is no "conjoint scheme" for England. The facts remain as heretofore, that a qualification either in medicine or in surgery entitles students to be placed on the Register; and there is no common standard for a minimum qualification. It is right, perhaps, to add to this brief statement, that the College of Physicians in England adds surgery and midwifery to its medical examinations, and is recognised as conferring a qualification in surgery and midwifery as well as in medicine, and that the College of Surgeons adds medicine to its surgical examinations, when a candidate has not a medical qualification. The Bills which are before Parliament need not detain the Council long to-day. The Council has partly gone into the subjects of both. See Minutes of Council as to Mr. Cowper-Temple's Bill, June 24, 25, 26, 1875; as to Public Health, July 7, 9, 1869. Mr. Cowper-Temple's Bill, the same as that of last year, will not, unless the Council change its opinion, be taken as an adequate settlement of the vexed question of women's admission to the Register. Nor is the Government likely, therefore, to promote its passage

(*a*) For the above figures I am indebted to the kindness of Dr. W. Farr, F.R.S., Dr. Burke, and Mr. Pitt Dundas.
(*b*) See Executive Committee, March 23, 1876.
(*c*) Branch Council for England, April 11, 1876.

(*a*) Vol. v. 280–286; vol. vi. 228–236.

through Parliament. At the same time, considering the opinion expressed by the Council in a report on the subject last year (June 26); considering the promise by the Government on the withdrawal of Mr. Cowper-Temple's Bill, that attention should be given to the question; and considering the Act obtained last year by the College of Surgeons of England, and its difficulties this year, with regard to granting licences in midwifery, it would seem both impracticable and impolitic to defer a settlement of the question. Mr. Gibson's Bill deals with two subjects only. The first is, the equality of qualification for certain offices in Ireland, on which information is required before the Council can ask the Government to support the Bill; the second is, the Registration of Public Health diplomas or certificates as an additional qualification. On this subject a committee of the Council has already reported. Mr. Ouvry also gave his opinion as to the form of a clause for a Bill recognising public health certificates. It was laid before the Council on March 1, 1870. This might be a proper subject for a committee, inasmuch as the Government has asked the opinion of the Council on Mr. Gibson's Bill, and awaits an answer before announcing its intentions thereon. This point, also, does not admit of delay. It may be remarked, that the Universities of Dublin, Edinburgh, Cambridge, Oxford, and London, have successfully instituted examinations in subjects bearing on public health. In a sanitary conference held in London, in the early part of May, and presided over by Lord Aberdare, it was suggested that the chief Medical Officers of Health should be required to have such certificates or diplomas. A report on the subject from the British Medical Association will be laid before the Council. There appears to be a growing feeling that the possession of certain professional attainments defined by the Medical Council, should, without regard to sex, be the condition of admission to the *Medical Register*. This is part of the general movement in modern society, and notably in England, America, and Russia, which may be cheerfully accepted by some who would not spontaneously promote it. There is a further conviction that there should be a completer and more systematic training for women who are engaged in midwifery, and a registration of those who are properly qualified according to a legal standard. As regards both of these propositions, the Council will doubtless feel, that if, either by an enabling or compulsory Bill, or by the creation of a new Examining Board, women are admitted to the present Register, and also classed in a Register of their own with special qualifications, still, there will remain many details with respect to education, hospitals, schools, and examinations, which will severely tax the attention of teachers and licensing bodies, and ultimately, and that before long, occupy this Council. The Rt. Hon. Russell Gurney indeed is prepared to bring in a Bill in which it is proposed that the existing licensing bodies shall be enabled, though not required, to admit persons to examination without regard to sex. This Bill will be shortly laid before you for consideration by desire of the Lord President, who has requested me to obtain your opinion thereupon at your earliest convenience. A communication from the President of the Council of Surgeons, regarding the position of the College in respect of midwifery licences, will be also submitted to you. But it would occupy the time of the Council too long to enter fully into these two subjects on this occesion.

One other detail requires notice to-day. A question was put by the Commission on the practice of subjecting live animals to experiments for scientific purposes, whether the Medical Council recommended the establishment of physiological laboratories, or whether the recommendation came from individual teachers, or the different medical corporations and licensing bodies (Q. 980). The subject had been advisedly postponed last year, and has not been discussed by the Council. But it is one of the class just now alluded to as requiring careful attention. A motion on the subject will be proposed for your consideration with regard to the Bill on cruelty to animals, introduced into the House of Lords by the Earl of Carnarvon.

In this connection it may be named that the Government desires to afford every facility to members of the Medical Council for examining the remarkable educational appliances and apparatus for scientific research, now collected at South Kensington, whether from England or from foreign countries. This valuable series throws light upon the question of the extent of training in physical science which is thought possible by various countries, either in ante-professional education, or in relation to technical professional studies. It may be quite right that time, money, and energy should be freely, nay lavishly, expended by great investigators, on matters which may be useless, even injurious, to ordinary students. It cannot be doubted that great freedom of action in this matter should be left to individual teachers of advanced students, while the Council collectively fixes the standard which is indispensable for attaining an adequate knowledge and skill for the practice of their profession.

The Council, in looking over the programme of work before it, will observe the number of committees which will be proposed for appointment.

The reports of visitors, as well as the observations upon those reports, that have yet to be considered, are numerous. The committee nominated on June 18, 1875, presented a report on June 25 on thirteen of the reports of visitations; and this is found in the Minutes of that date. Several important general questions are raised. The same amount of interest and industry bestowed for many years on this part of our duty by Dr. Parkes will, we may be sure, be brought to bear by Professor Humphry, whom the executive committee have asked to take up this work during your pleasure.

When the Reports of the Committees are before the Council either at this or a subsequent meeting, the Council will be in a position to revise the recommendations which it has issued, and on which it has received commentaries from the several licensing bodies. Of all these recommendations probably none will demand graver consideration than those which press on the nineteen Licensing Bodies the importance of combining to form Examination Boards, and those which suggest that no persons be placed on the Register who have not an adequate knowledge of every branch of their profession. The Council cannot fail to observe that the tendency to create new qualifications which press for admission to the Register, by the Bodies independently, has not diminished, as is shown by the independent action of the Universities in respect of the new Examinations in Public Health, and the concurrent desire expressed in various quarters to make these additional Qualifications or either admissible on the Register.

On all these and many other points, the free discussion, for which the meetings of this Council afford us an opportunity, is a great instrument for evoking order out of the disturbed conditions necessarily attending a transitional epoch, and a period of rapid, and on the whole satisfactory, progress. I will detain you no longer from the consideration of the various important subjects which will be brought before you.

On the motion of Mr. Quain, seconded by Dr. Storrar, resolutions were passed for the appointment of a committee to consider and report on (1) Mr. Cowper-Temple's Bill, with resolution of King and Queen's College of Physicians in Ireland; (2) Mr. Gibson's Bill, with resolution of King and Queen's College of Physicians in Ireland; (3) Letter from the Obstetrical Society of London, with the President's Letter to the President of the Royal College of Surgeons of England, and his reply thereto; (4) Report on State Medicine Qualifications from the British Medical Association; (5) Memorial from English Practitioners possessing Foreign University Degrees.

COMMUNICATIONS FROM THE LICENSING BODIES.

The next business was the reception of voluminous communications from the various licensing bodies upon

the reports presented last year by the visitors of examinations. These letters are, of cours, much too long for our columns, occupying as they do about forty pages of the Council's minutes ; our readers, however, will doubtless remember that in several instances severs strictures were passed by the visitors upon the methods and subjects of examination adopted which we fully reported and commented upon last session. The communications now presented consisted generally of explanations and suggestions of such individual cases, and in some promises of carrying out the recommendations of the visitors. The bodies who remitted communications on these topics were the Royal College of Physicians, London, the Royal College of Surgeons of England, the University of Oxford, the University of Durham, the University of Edinburgh, the University of Aberdeen, the University of St. Andrews, the King and Queen's College of Physicians in Ireland, the Apothecaries' Hall, Dublin, the Queen's Colleges of Belfast, Cork, and Galway.

THE GOVERNMENT BILL ON VIVISECTION.

A full abstract of this Bill having appeared in our last issue, before the meeting of the Council, we refer our readers to its provisions.

In moving for the appointment of a committee thereon, Professor Lister said he felt that no apology was required for bringing the subject before the Council, as every one must be satisfied that the Bill introduced by the Earl of Carnarvon was one that demanded very serious attention at their hands. Two courses had been suggested—one to appoint a small committee to consider the subject, and the other for the Council to resolve itself into a committee for that purpose.

Dr. A. Smith proposed that the Bill should be taken as read, and placed on the minutes.

Sir D. Corrigan opposed touching the question of vivisection at all ; he said the Council was established to enable the public to distinguish qualified from unqualified practitioners; it was a Council of Education and Registration, and he maintained that Lord Carnarvon's Bill came under neither of those heads.

Sir Wm. Gull replied that it was true the Council was an educational one ; on this account they were charged with the duty of supervising the course of study to be gone through by practitioners. He could not, therefore be otherwise than interested in any legislation which might tend to throw impediments in the way of the study of natural science. He agreed that the purpose of the Council was to enable the public to distinguish between qualified and unqualified practitioners. But how was a man to be qualified except through a proper course of study? It was the duty of the Council to decide what that course should be. It was not enough that a man should be able to pass an examination ; that might make him a qualified practitioner in a very qualified sense ; but this was not all that was to be desired.

Dr. Rolleston remarked that the subject was clearly within the domain of the Council, and he was in favour of its being taken into consideration. He might disagree with the views of Professor Lister on the subject, but everyone interested in the welfare of the medical profession would desire that the Council should give a distinct pronunciamento upon it.

Dr. Wood supported the motion for putting the Bill upon the minutes of the Council, and contended that the question was one having a material bearing upon the education of medical practitioners, and therefore coming within the scope of the Council's duties.

Dr. Smith's motion was then agreed to.

Professor Lister then renewed his motion for the appointment of a committee to consider the subject, which was carried, the following being appointed, Professor Lister, chairman ; Sir Wm. Gull, Dr. Allen Thomson, Mr. Teale, Mr. Simon, Professor Rolleston, Dr. Humphry, Mr. Turner, Dr. A. Smith, Mr. Lister.

RECOMMENDATIONS FROM THE LICENSING BODIES.

On the motion of Dr. Wood it was resolved—"That the observations on the recommendations and opinions of the Medical Council from the various licensing bodies be referred to the following Committe: Dr. Andrew Wood, Chairman, Mr. Bradford, Dr. Fleming, Dr. Thomson, Dr A. Smith, Dr. Apjohn, Sir Dominic Corrigan, Mr. Teale. And that it be an instruction to the Committee to consider the whole question of the registration of medica, students, together with the letter from Professor Harveyl of Aberdeen, concerning materia medica."

THE ARMY MEDICAL WARRANT.

Dr. Stokes rose to move "that a committee be appointed to take into consideration the recent warrant relating to the Army Medical Service." Dr. Stokes read a long speech which, we presume, was in furtherance of the foregoing motion, but as it was perfectly inaudible at the reporters' table, we are unable to say. Regretting our inability to give the opinions expressed by Dr. Stakes, it would be useless to chronicle the remarks made on his motion by other speakers. We must therefore content ourselves by adding that it was met by the following resolution of Dr. Thomson, seconded by Dr. Smith, and carried:—"That it does not come within the province of the Council to take into consideration the recent Warrant for the Army Medical Service."

The Council then adjourned.

Thursday, May 25th,

was a *dies non* for the reporters, the Council assembling but for half-an-hour to confirm the minutes of the preceding day, then resolving into various committees for the remainder of the day.

Friday, May 26.

The following questions were put to the President:—

1. Dr. Andrew Wood asked "in what state the negotiations of English bodies, as regards the conjoint scheme, are at the present time."

2. Mr. Turner asked if he could inform the Council what resolutions the several licensing bodies that have been negotiating for the formation of a conjoint board for England have arrived at.

The President replied as foliows :

"With respect to the first question, I have to state that the nogotiations are incomplete.

"As to the second : On the 30th of March, 1876, at a meeting of the conference of all the medical authorities in England, held at the Royal College of Surgeons of England, it was resolved—

> 'That the conference of representatives appointed by all the medical authorities in England, adopt the scheme for an examining board for England as this day amended, and submit the same to the several medical authorities for their consideration.'

"This scheme as amended was forwarded to all the licensing bodies by Sir James Paget, Chairman of this Conference.

"The University of Oxford has replied assenting to the scheme. The University of Cambridge has replied that the Syndicate appointed to consider the scheme are unable to recommend the University to approve the alterations proposed to be made as to the appointment of examiners. The University of London has not replied. The University of Durham assents. The Royal College of Physicians approves the amended scheme, as does the Society of Apothecaries. The Royal College of Surgeons approves, if all the other bodies agree.

"It is proper to state that suggestions have been made by Oxford, the College of Physicians, and the College of Surgeons. These need not be expected to cause any serious difficulty if the scheme be generally agreed to."

3. Mr. Quain asked if he could give information with regard to a "conjoint scheme" in Scotland and in Ireland.

The President replied as follows:

"I am not aware that any communication has been addressed to the President of the Council on the subject of the conjoint scheme, either for Scotland or Ireland, since the last meeting of the Council. Observations and resolutions on the subject of these schemes are to be found in every year from 1869 inclusive. The last was, I believe, on June 26, 1875."

A letter was received and entered on the minutes from the Board of Trade, referring to a report from the superintendent of mercantile marine at Poplar, in which it was suggested that when registering medical practitioners their diplomas should be endorsed as a proof of registration.

THE TEACHING OF MATERIA MEDICA.

The following letter from certain Lecturers on Materia Medica was read, and on the motion of Dr. Wood was referred to the committee on the recommendations of council:

SIR,—We, the undersigned lecturers on Materia Medica and Therapeutics in the medical schools of London, desire to tender our best thanks to the general medical council for the consideration bestowed by them upon our memorial of June, 1875, and respectfully to ask what reply, if any, has been received from the licensing bodies to the recommendation based upon our suggestions.

We beg leave to express our general concurrence with Professor Harvey in his letter recently addressed to you, and are of opinion that a further recommendation from your council to the *London* medical schools would materially aid us in carrying out the objects we have in view, viz.:—

1st. The postponement of the course of Therapeutics to a later stage of the curriculum; and

2nd. The amplification and more practical development of the teaching of Pharmacy.

Signed.—FREDK. J. FARRE, St. Bartholomew's Hospital; T. LAUDER BRUNTON, SYDNEY RINGER, University College Hospital; E. BUCHANAN BAXTER, King's College Hospital; JOHN C. THOROWGOOD, Middlesex Hospital; CHARLES D. F. PHILLIPS, Westminster Hospital; R. DOUGLAS POWELL, Charing Cross Hospital; J. F. PAYNE, St. Thomas's Hospital; W. MOXON, Guy's Hospital; ROBERT FARQUHARSON, Hon. Sec., St. Mary's Hospital.

ENGLISH CERTIFICATES OF LUNACY IN SCOTLAND.

A letter from Dr. Stewart Lockie was entered on the minutes. This letter referred to the invalidity of English medical certificates for the admission of lunatics into Scottish Asylums, and it was moved by Dr. Haldane and seconded by Sir William Gull:—

"That as the limitation of the validity of lunacy certificates to the division of the Kingdom in which they are first given is still a pressing grievance, the President be requested to lay before the Home Secretary all the previous acts of this Council on the matter."

SATURDAY, MAY 27.

The Council assembled two hours earlier than usual for the purpose of receiving and discussing the—

REPORT OF THE COMMITTEE OF THE GENERAL MEDICAL COUNCIL ON LORD CARNARVON'S BILL INTITULED "AN ACT TO PREVENT CRUEL EXPERIMENTS ON ANIMALS."

The Report of the Committee was as follows:—"The Committee having considered the Earl of Carnarvon's Bill, intituled "An Act to prevent Cruel Experiments on Animals," recommend to the Council to address her Majesty's Government to the following effect:—

This Council being charged by law with the duty of superintending the course of medical studies in this country cannot be indifferent to any legislation affecting physiological teaching and research.

The General Medical Council while deeply impressed with the importance of avoiding the infliction of needless pain in the performance of experiments on living animals, regard such experimentation as indispensible to the advancement of a physiological and medical knowledge.

The Council are not aware that in regard to these experiments such abuses have existed in the British Islands as to justify exceptional legislation restrictive of physiological study and research; but they would nevertheless be glad to assist the Government in framing a measure which may give all reasonable securities against any possible abuse.

The General Medical Council would respectfully suggest to her Majesty's Government that the following amendments should be made in the bill:—

(*a*) In clause 3, sub-clause 1, the performance of experiments is limited, "with a view only to the advancement by new discovery of knowledge which will be useful for saving or polonging human life, or alleviating human suffering." The General Medical Council would remark that any proposal to limit experiments to such as may be immediaaely applied to some prophylactic or therapeutic end, and to forbid them in cases where they are made purely for the advancement of science, is contrary to the opinion of the Royal Commission on the practice of subjecting live animals to experiments for scientific purposes, as expressed in their report (p. xviii.) where it is pointed out that such a "proposal cannot be sustained by reflection upon the actual course of human affairs. Knowledge goes before the application of knowledge, and the application of a discovery is seldom seen when the discovery is made." Further the Council would remark that this sub-clause, by limiting experiments to those which will be useful for saving or prolonging "human" life, or alleviating "human" sufferings, would prevent researches from being carried out with reference to the prevention and treatment of the diseases of the animals themselves. The Council would therefore recommend that the following be substituted for clause 3, sub-clause 1:

That the experiment must be performed with a view to the advancement or to the commnnication of physiological or medical knowledge.

(*b*) The limitation of all experiments to registered places, as proposed in Clause 3, sub-clause 2, would not only tend seriously to obstruct genuine scientific inquiry, but would also prove impossible in practice. The General Medical Council, however, would see no objection to the limitation being applied to such experiments as are performed for purposes of demonstration. Physiological laboratories, and other public institutions in which experiments on living animals might be carried on for educational purposes, would thus, by a further provision of the Bill, be subjected to visitation by Inspectors; while private researches which, in competent hands, might prove of the highest value to mankind, and ought by no means to be prohited, would, by the system of personal license and certificte, provided for in other clauses, be restricted to individuals of assured character and attainments. The Council would accordingly suggest that the sub-clause be amended, as follows:

The experiment *if for purposes of demonstration* must be performed in a registered place.

(*c*) In sub-clause 1, page 2, line 17, after the word "forgoing," the words or *following* be inserted; and that in line 22 the word *due* be inserted before "instruction"; also that after the word "knowledge," in line 24, the remaining words in lines 24 and 25 be omitted.

(*d*) With reference to clause 4 the Council are of opinion that in the present state of knowledge as to the properties of *curari* or *curare*, it is inexpedient for Parliament to declare, as in this Bill, that this drug shall not, for the purposes of the Act, be deemed an anæsthetic. They would see no objection to the enactment in lieu of clause 4, of the following:—

That no substance should be deemed to be an anæsthetic until it has been proved to be so.

(*e*) As to clause 5, the General Medical Council do not see sufficient reasons for specially exempting dogs and cats from experiments. On the contrary, they feel that such exemption would withdraw from investigation carnivorous animals of great value for the purposes of research; whilst further the communicability of certain diseases (*Rabies—Hydrophobia*, and the diseases dependent on the *Tapeworm—Echinococcus*) from these animals to man, renders it specially inexpedient that the dog and cat should be exempted from experimental inquiry.

(*f*) That an order to bring clause 7 into accordance with the suggestion made under clause 3, sub-clause 2, the Council

would suggest the insertion in line 26, after the word "place," of the words *to be registered*.

(*g*) The provisions of clause 9 appear to the Council not only beyond the necessities of the case, but such as might be made vexatious and oppressive. The Council would suggest that the objects of the Act would be carried out by the following clause:—

The Secretary of State may in any case, where he deems it necessary, call upon any person licensed under this Act to to supply him with information respecting experiments carried on under this Act.

(*h*) As regards clause 10, the General Medical Council think it indispensable for the just working of any system of inspection under this Act, that every person appointed to act as an Inspector should be scientifically competent to appreciate the nature and intention of such experiments as he may witness; and the Council would therefore recommend that such modifications be made of clause 10 as may secure this essential object.

(*i*) To the list of Presidents named in clause 11 should be added:

The President of the Royal Society of Edinburgh, the President of the Royal Irish Acadamy, the Vice Chancellors and Principals of the Universities in Great Britain or Ireland:

And also that the professors of medical jurisprudence and materia medica should be added to the list of professors named in the Bill.

To persons in the higher ranks of science engaged in special research the frequent application for a certificate, such as seems to be required in clause 11, would seriously interfere with their labours. The Council would therefore suggest that the following addition be made after the word "section" to the last paragraph of that clause.

And may also, on recommendation of the functionaries above specified, exempt by special licence any licensed person approved of by them from the necessity of producing such special certificates as are mentioned in clause 3.

(*j*) In the matter of appeal in clause 16, the Council are of opinion that any licensed person who thinks himself aggrieved by the judgment of a court of summary jurisdiction should have the option of appealing to a superior court instead of the court of quarter session.

JOSEPH LISTER, *Chairman.*

Before proceeding with the discussion of this Report:—

Sir Dominic Corrigan asked leave to move an amendment to the effect thatwhilst, heartily concurring in the desire of preventing any needless infliction of pain on the lower animals, it was not within the province of the Council to interfere with Her Majesty's Government, inasmuch as their advice had not been sought.

Dr. Aquilla Smith seconded the amendment, but the President ruled that it could not be put, the Council having already decided to take action in the matter.

The Report was then discussed paragraph by paragraph in committee of the whole Council. The first paragraph passed without discussion.

Professor Lister thought that as the welfare of the public was inseparably connected with the progress of physiological research, which could not possibly be carried out unless necessary experiments were permitted, paragraph two needed no words from him to recommend its adoption by the Council.

Sir Wm. Gull was perfectly astonished to find that in a country like this the Government should proceed with the legislation of such a momentous question without first ascertaining the views of that Council, which was certainly in a better position than any other body in the land to know the merits or demerits of the subject, and that the knowledge that such a Bill was intended to be introduced should be left to accident, or the chance of seeing it in the public press. One of the duties of the Medical Council was to determine and to supervise physiological studies, yet the Government had initiated the monstrous precedent of interfering with the rights and privileges of the Council without the shadow of courtesy or consideration; he therefore would give his hearty support to this paragraph, which expressed their surprise and annoyance at such proceeding.

Dr. Allen Thomson deemed it of great importance that the protest of each individual member of the Council should go forth to the public in order to establish their position as stated by Sir Wm. Gull. To this end he proposed an addition expressing even more strongly the annoyance they felt at the course the Government had thought fit to pursue.

Sir Dominic Corrigan, on the contrary, considered that the Government had acted in a perfectly legitimate manner. He was still of opinion that the discussion of vivisection did not come within the province of the Council, whose principal duties were to see that students obtained a full and sufficient, education not to legislate with the view of seeing they got more than was necessary, that might be left to circumstances and their teachers, not to the dictation of the Council. He charged Sir Wm. Gull with only partially quoting passages in chapters 20 and 21 of the Medical Act of 1858 to suit his case, whereas, had he read such quotations in their entirety, a totally different construction would appear. He was aware Sir Wm. Gull objected to the Government pursuing their course without the action of the Council, but the subject under discussion not coming within their province as he took it, gave them no right of appeal to the Privy Council. He was forcibly reminded of a common expression made use of in Ireland: "Don't put your poker in another man's fire," which he would advise the Council to act upon in this case.

Dr. Andrew Wood thought Sir Dominic's arguments most fallacious; physiology was one of the subjects required by the Council; therefore, as physiological experiments could not be carried on if the Bill of the Government became law, it was clearly the duty of that Council to interfere, even if they could not stop the passage of the Bill through the House, at least, to modify it, so that the students of this country should not be placed in a false position.

Mr. Quain, Dr. Pitman, and the President objected to the rider suggested by Dr. Thomson, and the latter in deference to such wishes withdrew it, and the paragraph as it originally stood, that "This Council being charged by law with the duty of superintending the course of medical studies in this country cannot be indifferent to any legislation affecting physiological teaching and research," passed.

Paragraph 3 provoked considerable discussion; it ran as follows:—"The General Medical Council while deeply impressed with the importance of avoiding the infliction of needless pain in the performance of experiments on living animals, regard such experimentation as indispensable to the advancement of physiological and medical knowledge."

Professor Lister in moving its adoption pointed out a few of the absurdities with which the public mind was beset in their agitation against vivisection. They had two things to consider, the taking of life and the infliction of pain. The public dined and feasted upon fish, flesh, and fowl, but these being matters for their comfort and enjoyment, they never cared to ask themselves, the amount of suffering these living creatures passed through whilst under preparation for their meals. They boiled lobsters alive, crimped salmon and skate alive, skinned eels alive, inflicting fearful torture for their enjoyment; yet when scientific men were engaged in the prosecution of some necessary investigation which might benefit the whole human race, they raised a hurricane of abuse, because an incision had been made in the skin of a kitten, or a frog had been subjected to what they called a brutal experiment. Where was the logic of this virtuous indignation? These very people set traps for rats, the wretched animals were caught by the legs, and for hours suffered the most acute agony, in the endeavour to get free, even as it sometimes happened with the loss of a leg or two. They allowed cats to torture mice for hours, enjoying what they considered the fun of the thing, yet they never deemed it worthy a moment's consideration that these poor animals were undergoing a terrible

amount of physical and mental suffering. Worse even than these, the torture inflicted in what was called sport was indescribable ; the hours of mental and physical suffering endured by the fox, who was finally worried to death by the dogs ; the maiming of pheasants and other game, which struggled back to their nests or their holes to suffer the most excruciating agony for days after being partly killed "in sport," was monstrous to think of. Yet the justifiable infliction of pain in the cause of scientific research, in which the public were more enduringly interested than in the cruelties of so-called sport, was more microscopical in the whole year than a single day's pigeon-shooting. But while he would not maintain that vivisection was absolutely indispensable, yet, as it inflicted no moral wrong while governed, as it had been proved to be, by humane principles, it was as necessary for the public as the profession, and it would be well the public should know this. With these philosophical remarks he commended paragraph 3 to the acceptance of the Council.

Dr. Humphrey remarked that in the race of life man suffered both moral and physical deterioration, and were it not for those hidden mysteries which medico-physiological research revealed for the benefit of humanity, man would be in a bad state indeed. The grandest discoveries of science, which had redounded for the glory and comfort of man, could not have been made but for the experiments upon the living structure ; the mind, if he might so term it, of dead structure had already been worked out, and it could only be upon the living process that observations could be made. Of such vital importance did he deem the subject, that the welfare of future generations and the position of this country in the world of science and advancement would seriously be affected, and a consequent decadence the result. For his part, he could honestly say that he never witnessed an experiment in which needless pain was inflicted. The public mind had been unduly influenced by agitators, who fished in every hole and corner, digging up reports and cases from times immemorable, in order to give a fictitious weight and importance to their case ; whilst those useful investigations from which humanity at large had so largely benefited were kept in the background. Before resuming his seat he desired to enter his protest against the narrow-minded view with which the medical profession had been taunted—viz., that if vivisection were rendered illegal, our students would pass to other countries where it was permitted, and we should suffer a monetary loss : nothing could be more monstrous ; the profession took a much more enlightened view; they knew that it was absolutely necessary, and if once stopped, would be the first and surest step this country could take towards an inevitable decadence.

Dr. A. Smith drew attention to the fact that if the Bill of Lord Carnarvon's became law, it would render it impossible to castrate our domestic animals, as was now the universal practice ; the public little knew what consequences their agitation would lead to.

Sir Wm. Gull wanted to know why the profession were to be instructed to prevent cruelty to animals? Who, but they had invented anæsthetics to relieve and reduce pain to a minimum? Who but the immortal Harvey established the circulation of the blood by experiments upon the living tissue, leaving a legacy to all times for the Fellows of the College of Physicians to stir up the profession in the pursuit of physiological research. Were they, then, 240 years after, to be treated as schoolboys, and called upon to convince the public that experimentation was necessary? There was nothing greater than the cruelty of ignorance, from which the public were suffering not inconsiderably on this very question.

Dr. Rolleston said the subject was not a new one, this outcry and clamour had been excited in the public mind for many years past; he well remembered it in 1863, and thought therefore that they should strive to settle it at once. Upon a show of hands paragraph 3 was declared to be carried.

Paragraph 4 was then divided into two, the following part being first considered, which runs thus:—"The Council are not aware that in regard to these experiments such abuses have existed in the British Islands as to justify exceptional legislation restrictive of physiological study and research."

Professor Lister wished to remark as the mouthpiece of the Committee, that the public had ample safeguards against needless infliction of pain in animals in the humanity which always guided the profession ; he also felt certain that if wanton or cruel experiments were indulged in by teachers, no class of students would be found to tolerate them.

Dr. Humphrey was aware that it would be impossible to provide against an occasional abuse of any privilege, but when such exceptions were taken against the immense amount of good, it would be infinitesimal.

Sir Wm. Gull wished it to be known through the press that the accusations that had been made against the Brown Institution of cruel and useless experiments was a base calumny, the evidence given before the Commission of Inquiry showed that there was not the slightest justification for the charges that had been made.

Mr. Macnamara, on behalf of the Irish Colleges, protested that needless experiments were never carried out, and where experiments for the purposes of physiological investigation were necessary, humanitarian feelings always guided the actions of the teachers.

Professor Turner said the paragraph under discussion rightly expressed their views, that there existed no reason for exceptional legislation upon the subject. It was an insult to common sense, and a cruel and undeserved censure upon those gentlemen who sacrificed so much valuable time and attention on behalf of the public in biological experimentation.

Dr. Thomson also spoke to the same fact.

Dr. Quain entered upon the defence of Dr. Klein, of the Brown Institution, whose evidence the Royal Commission had twisted in the very opposite direction to that intended by that gentleman. The Master of the Rolls, as Chairman of the Commission, had most minutely investigated the subject as connected with the Brown Institution, and the result was a complete refutation of the charges made. To give the Council an idea of what was actually done, Dr. Quain quoted a few passages from his evidence. Dr. Klein denied that he had a private class for these experiments, as stated. During the year he had performed *only two experiments where necessary pain* was inflicted, the cauterisation of the cornea of a frog, the injection into the blood-vessels of the same animal, and the cauterisation of the cornea in a kitten, under chloral hydrate, which was given to keep the animal quiet. Only ten or twelve animals were sacrificed to these experiments in the year, and these the lower animals, frogs in the greatest number, and only one kitten. He had made but one experiment upon a living kitten, and this for teaching purposes. Yet, continued Dr. Quain, this was the man who was held up to abhorrence by an ignorant public ; these the fearful and heartrending experiments upon which exceptional legislation was deemed necessary !

Mr. Simon explained that Dr. Klein's name was held up to abhorrence not for his practices, but for the sentiments he was supposed to hold. He considered him most unfairly dealt with, and congratulated Dr. Quain upon his defence.

Paragraph 4 was then agreed to, and the following paragraph—"they would nevertheless be glad to assist the Government in framing a measure which would give all reasonable securities against any possible abuse"—with various alterations and additions, occupied the attention of the Council for the remainder of the day.

Dr. Wood thought the clause they were considering a most illogical one ; it expressed a gladness which they did not feel, and committed the Council to a course of which they disapproved. He suggested that, as legislation was inevitable, they should insert the word "if," so that it might read, "if legislation on the subject is deemed advisable, they would assist," &c.

Dr. Rolleston could not agree with Dr. Wood ; legislation was not only inevitable, but desirable. As Dr. Quain had entered upon the praiseworthy defence of Dr. Klein, he would

do so on the other side for Professors Erichsen and Huxley, who drew up the elaborate and exhaustive Report of the Royal Commission, and whose opinions and evidence could not be disregarded. These gentlemen had stated that great carelessness existed in the conduct of experimental inquiry, and that reasonable securities ought to be given against the needless infliction of pain. Their Report contained a most beautiful and classical metaphor, which he considered went far to upset the notion, that unless men were allowed to experiment upon living animals without restriction the chances of discovery were very remote. Dr. Rolleston then quoted the following views of Professors Erichsen and Huxley :—

"It has been proposed to enact that the object in view shall be some immediate application of an expected discovery to some prophylactic or therapeutic end, and that any experiment made for the mere advancement of science shall be rendered unlawful. But this proposal cannot be sustained by reflection upon the actual course of human affairs. Knowledge goes before the application of knowledge, and the applications of a discovery is seldom foreseen when the discovery is made. The first origin of a great discovery is often like the germ of the natural life in an animal or a vegetable, so small as to be scarcely perceptible, and yet it may contain in it the seeds of the grandest results."

Dr. Rolleston concluded by expressing his entire concurrence with these views. Not only did the interests of medical education and those of the profession demand immediate legislation, but the moral sense of the community must be taken into account. It would prevent public scandal, allay suspicion, and be the means of bringing in valuable recruits from the public (who had now taken up the cry indiscriminately), if the subject were met by them in that catholicity of spirit which its importance demanded.

Sir Dominic Corrigan expressed a contrary view, quoting Talleyrand's advice when news of a panic was brought to him. He said panics in the public mind must be met by doing nothing; they quickly wear themselves out. The present one was got up by a few agitators, and supported by a number of good-intentioned ladies. He conversed with one of these latter the other day, who told him, in the course of conversation, that she had eaten oysters for lunch. Upon his asking her, as an anti-vivisectionist, if she was not ashamed of cutting up and swallowing these creatures alive, she replied that the oyster did not oppose it, and therefore it had no feeling. He then reminded her that the oyster's opposition to being opened was so strong that an instrument of torture had to be invented to open it. Its living and throbbing muscular tissue was then cut across, cayenne pepper and vinegar added to its agony, and the wretched creature gulped down alive, to gratify the fancies of her appetite. The lady was, of course, shocked; yet these, added Sir Dominic, are the people by whom the panic is kept up. He, however, was convinced that the good sense of the House of Commons would not pass a measure which was nothing less than humbug.

Dr. A. Smith was of opinion that, after the expressions of that Counil had gone forth to the public, the Government could not and would not attempt to pass a Bill which would render future physiological experiments illegal.

Sir Wm. Gull expressed similar views, and condemned the indiscreet words used in the House of Lords by Lord Cardwell, which showed conclusively that the mind of this statesman, for whom he entertained the greatest respect, had been influenced by the popular clamour.

The President expressed an opinion that it would be futile to attempt to stop legislation on the subject, and advised offering their assistance to the Government, notwithstanding their conviction that the outcry was not justifiable, nor exceptional legislation necessary.

Dr. Wood then moved the adjournment of the debate until Monday, which was carried.

Monday, May 29th.

After confirmation of the Minutes, the Council in committee resumed the discussion on the Report of the Vivisection Committee, which will be found in Saturday's proceedings. Space and time prevent our recording more than the fact that the remaining clauses of the report were passed with some slight emendations, and the Council then resumed, but owing to the lateness of the hour, the Report as amended by the Council in committee was deferred, that it might be considered in conjunction with the whole Bill.

Literature.

CLINICAL REPORT OF THE ROTUNDA LYING-IN-HOSPITAL. (a)

It is with the greatest pleasure we notice the appearance of the seventh (and, we regret to say it, final) Report of the Rotunda Lying-in Hospital. It would be impossible to overrate the value and importance of these reports. They are founded upon the most careful and conscientious observation and record of indisputable facts. He has, we think, admirably succeeded in accomplishing the task which he marked out for himself at the commencement of his official career, *i.e.*, of demonstrating, upon the basis of incontrovertible facts, the comparative safety of large maternities, when well and carefully managed, as asylums for the poor creatures who are compelled to seek refuge in them; and that in the majority of instances where patients become the subjects of any form of fevers, or other dangerous complications of the puerperal state they have either contracted the seeds of the disease previous to their admission, or their labour has been allowed to overtask their strength for want of timely interference and instrumental delivery.

In a necessarily brief review, it would be impossible for us to do full justice to the pamphlet under consideration, bristling as it is with information, statistical and otherwise, in every page and every line. To be properly appreciated, it should be read and considered *in extenso*. We must compliment Dr. Johnson most highly for the clear and concise manner in which he has tabulated the results of his large experience and observation. We believe that these tables will long be a standard of reference for the profession at large upon most questions of obstetric interest, and most cordially join in the hope expressed by several members of the Obstetrical Society that these reports may be brought together and published by their author in one volume; as a standard book of reference upon the points of interest coming within its scope it would be simply invaluable.

Of the 1,065 cases of labour that took place in the Hospital during the past year, the following is a brief summary, quoted in Dr. Johnson's own words :—

"813 were perfectly natural, *i.e.*, the head presented; the child was born within 24 hours, without any artificial aid, or any untoward circumstance occurring; the placenta was expelled by the natural efforts, and there was no *post-partum* hæmorrhage. 40 were abortions, *i.e.*, the ovum or embryo was expelled from the sixth week to the end of the sixth month of pregnancy. In two instances the child presented with the upper extremities, and in 37 with the lower. We considered it advisable to deliver in 113 instances with the forceps. In 5 cases craniotomy had to be performed, and in four instances we performed version. Labour was induced in 2 instances.

"In 11 instances the labour was complicated by twins, in 1 by triplets, in 4 by convulsions; there were 11 cases of accidental hæmorrhage, 2 cases of placenta prævia, 31 of *post-partum* hæmorrhage, viz., 26 trivial, or comparatively so, and 5 serious, 15 of retained placenta, 4 cases of prolapse of the funis. Chloroform was administered in 100 cases."

Dr. Johnson is strongly in favour of early delivery with the forceps where there is threatening of serious danger to the patient, owing either to the prolongation or severity of the labour. He does not consider the want of complete dilatation in the os uteri to be a bar to the application and use of the forceps when they are in the hands of a skilful practitioner, and when they are both applied and used with proper caution. Our own experience induces us to

(a) "Clinical Report of the Rotundo Lying-in Hospital" for the year ending 5th November, 1875. Compiled by the late Master, Dr. George Johnson, and read by him before the meeting of the Dublin Obstetrical Society, at their meeting, Jan. 8th, 1876.

agree with Dr. Johnson in the necessity for and benefits accruing from such early interference, when properly carried out, in carefully considered cases. Under no circumstances must their use be a mere question of convenience to the doctor, but must depend upon the circumstances of the case as affecting the safety of the mother and child. In support of his opinion as to the safety and innocuousness of the forceps when skilfully handled, Dr. Johnson quotes the fact that, in 752 cases in which they have been used during the last seven years, no single instance has occurred in which injury has been inflicted upon the soft parts of the mother, a fact that reflects the highest credit upon Dr. Johnson's caution and skill.

The mortality amounted to 27 from all causes, or about 1 in 39½. At first sight this seems a very high rate, but in reality it is not so, as the author of the pamphlet has very admirably shown in his careful inquiries into the circumstances and history of each case, which he has clearly set forth in both tabular and detailed form. We quote a brief analysis of these cases in his own words :—

"There were 10 cases of seduction, suffering more or less from great distress of mind ; 2 fretting from having been deserted by their husbands ; 5 in extreme delicacy of health, some having pyæmia upon them on admission ; 2 cases of scarlatina ; 1 bronchitis, pleuritis, and pneumonia ; 1 diarrhœa, terminating in peritonitis ; 1 fungoid tumour of the uterus and fatty heart ; 2 peritonitis ; 1 renal disease."

We regret space and time forbids our dwelling further upon the subject matter of these admirable reports ; they reflect the highest credit upon their author, upon the institution of which he was Master, upon the Dublin Obstetrical Society, of which he is such a prominent and honoured member, upon the Dublin School of Medicine, and, lastly, upon the medical profession in Ireland generally. We close our remarks with the renewed expression of our desire that Dr. Johnson may be induced to publish these reports in a collected form, for the sake of all those who are interested in the progress, on a scientific basis, of the stetric branch ofb o pourrofession.

Healing of a Perforating Wound of the Stomach.

(Fischer : *Centralblatt für die Med. Wissenschaften*, No. 55, 1875 ; from *Deut. Med. Wochenschrift*, 1875, No. 11.)

The ball passed between the fifth and sixth rib of the left side, and without touching the lung perforated the diaphragm, making a round hole in it, went through the anterior and posterior walls of the stomach, and remained back of the quadratus lumborum muscle. The wounds of the stomach healed without giving rise to any disturbance, probably because at the time of, and for a considerable space of time after the infliction of the injury, the organ was empty. At the post-mortem examination, distinct cicatrices of the size of a small coin, which were partially pigmented, were found. False ligaments existed between the diaphragm and the anterior wall of the stomach to its greater curvature, to the left lobe of the liver, and from the fundus of the stomach to the spleen. In the lower part of the left pleural cavity there were numerous adhesions between the pleura, lungs, and pericardium.

On the Occurrence of Inosite (?) in the Urine of Rabbits.

(Dr. E. Külz : *Centralblatt für die Med. Wissenschaften*, 1875, No. 54.)

Bock and Hoffman have shown that rabbits become diabetic when a solution of common salt of the strength of 1 per cent. is continuously injected into their blood-vessels. In view of the fact that in both diabetes mellitus and insipidus inosite was sometimes found in small quantities, it was supposed that there would be an excretion of this substance in the large amount of diabetic urine produced by the administration of the chloride of sodium. It was found upon investigation, in eight experiments performed with a view to settle this question, that inosite was present in the urine in each case.

Clinical Records.

ST. MARY'S HOSPITAL.

Under the care of Mr. Norton.

Case of Strangulated Inguinal Hernia—Reduction en masse by Taxis—Continuance of the Symptoms—Operation—Recovery.

(Reported by Mr. Sworder.)

A. B. was admitted on the 29th of March, 1876, at 6.30 a.m., with all the symptoms of a strangulated hernia. He stated that he had been ruptured for six months, and that he had never been able to find the right testicle. He had been able to reduce the rupture without trouble, and to retain it in position by an ordinary inguinal truss. On the morning referred to the hernia descended at 3 p.m., and he was then unable to return it. He obtained medical advice, but as the hernia was found to be strangulated, he was sent on to the hospital. On examination a large inguinal hernia was found on the right side, which was tense and painful, the pain extending into the abdomen ; there was no impulse on coughing. He was put into a warm bath and taxis applied, but without result. An ice-bag was then placed on the tumour, and, after three hours, nearly the whole mass was easily pressed back into the abdominal cavity. There then remained a tumour rather smaller than a hen's egg, soft and fluctuating, but without impulse on coughing. No intestine could be felt within the tumour nor within the inguinal canal. The symptoms of strangulation had at this time disappeared, he had no pain, and he did not vomit. Towards evening the patient vomited again, but the vomit was only milky fluid containing bile, and not stercoraceous. He slept fairly through the night, but on the following morning, March 30th, the vomiting continued, though still only curdled milk ; the countenance was somewhat anxious. Mr. Norton now saw the case, and formed the opinion "that the hernia had been reduced *en masse*, that in its reduction some part of the gut had been pressed through the stricture, a small knuckle yet remaining at the neck of the sac, and the rest of the sac containing fluid was that which was detected external to the abdomen."

He operated in the usual manner, and on opening the sac, about 3 oz. of pale, serous fluid escaped, and the testis was seen attached in inguinal the canal. On pressing upon the abdomen, a knuckle of strangulated intestine was made to protrude ; the neck of the sac was at least 2½ inches from the external abdominal ring, and the strangulation was at that point : the constriction was divided and the hernia readily returned. This hernia, which was of the congenital variety, was evidently due to the position of the undescended testicle ; the intestine had not been tightly constricted by the neck, and consequently the fluid in the sac was not sanious, and the symptoms of strangulation, though sufficient to diagnose the condition, were markedly mild in character.

March 29th.—He had ⅛ gr. of morphia one hour after the operation. Diet, milk and ice. At 10 p.m. very little abdominal pain. Temp., 98·2 ; pulse, 96.

30th—Slept very little. Much diarrhœa in the night. ℞. Tinct. opii., ℥xij. ; tr. lavand. co., ℥xx. ; sp. ammon. co., ℥xx. ; aquæ. ℥i. ; t.d.s. ; three doses only. Temp. 98·8 ; pulse, 84. Very little abdominal pain. As the diarrhœa continued, he was ordered an enema of twenty minims of opium ; this stopped it for some hours. Temp., 99 ; pulse, 80.

April 1st.—Pulse, 76 ; temp., 101·2. As the diarrhœa continued, he was ordered ℞. Pulv. aromat ℈ss. ; tinct. opii, ℥xij. ; liq. ammon., ℥x. ; aq. camph ℥i., to be taken after every motion. He only required two doses. The wound was looking rather puffy, as if matter were forming. A linseed poultice was applied. Temp., 99 ; pulse, 80.

2nd.—Slept well ; no return of diarrhœa ; no abdominal pain ; some pus came away through the wound, and on

probing a good deal came away: both extremities of wound have healed by first intention.

From this time the patient progressed without any bad symptoms, and left the hospital wearing a truss on the 26th of April.

THE SALE OF FOOD AND DRUGS ACT, 1875.

This Act (38 & 39 Vict., cap. 63) came into operation on the 1st October last. It has repealed all the previous general Acts relating to the sophistication of food, drink, and drugs. The experience which I have of the working of this Act, short as it is, leads me to conclude that it is defective in the following respects:—

1. It affords no protection to persons who only discover when using it that the food, &c., which they have bought is adulterated. Every person to be in a position to prosecute an adulterator of food, &c., must at the time of purchase notify to the vendor that he intends to have the article analysed, and he must offer to divide the article into three parts, and to give one of them, sealed up, to the vendor. It is evident that only an inspector will purchase food under such circumstances; and, therefore, if a private person finds that a spurious article has been palmed off upon him, he is not in a position to prosecute the vendor, at least under the provisions of the Sale of Food and Drugs Act. The former Acts enabled prosecutions to be undertaken against any person who sold an adulterated article; for, when the machinery for making available the Public Analyst's certificate as evidence was not taken advantage of, the Public Analyst, or any other competent chemist, could prove as to the adulteration according to the ordinary rules of evidence.
2. The Sale of Food and Drugs Act permits, in effect, the retail trader to sell an adulterated article, providing that he can prove that he sold it as he bought it from the wholesale trader. Several vendors of adulterated mustard in Dublin have escaped a penalty by showing that they sold it in the same condition as they purchased it from English manufacturers. I hold, however, that the vendor should be responsible for the article which he sells. He himself, if he were sold a spurious article by the wholesale dealer, would, and constantly does, hold the latter responsible, and would not accept from him the excuse that he sold the article in the same state as he imported it, or purchased it from the manufacturer. Mustard is sold at from 5d. to 1s. 8d. per lb., and the retail dealers, if they were afraid of being fined for selling this article mixed with 60 or 70 per cent. of flour, would soon take good care that they bought a pure article, which can always be got at a fair price. These observations apply to almost every other article as well as mustard.
3. In the former Acts of Parliament relating to adulteration, the Magistrates trying cases for breach of their provisions were empowered to award such costs as might to them seem reasonable. No such power is given to the Magistrates in the recent Act. Let us suppose the following case:—A private person in a country district finds that an article of food supplied to him is habitually adulterated. He obtains a sample for the purpose of analysis, under the provisions of section 14 of the Sale of Food and Drugs Act. The Public Analyst reports that the article is adulterated, and the purchaser summons the vendor before the Magistrates sitting at Petty Sessions. The defendant insists (as he is entitled under section 21 of the Sale of Food and Drugs Act) on the production of the analyst in court. The prosecutor, under those circumstances, must bring the analyst perhaps a distance of 100 miles, and at great cost; and, should he succeed, he is not entitled to the penalty imposed (see sec. 26), being a private prosecutor, nor can he be allowed more than 20s. costs, as the case comes under the provisions of the Petty Sessions (Ireland) Act, 1851.
4. Section 13, which relates to the appointment of Inspectors, is so clumsily worded that the meaning of its framers cannot be clearly made out. It states that the persons who alone can act as Inspectors under the Act are "any Medical Officer of Health, Inspector of Nuisances, or Inspector of Weights and Measures, or Inspector of a Market, or any police constable, under the direction and at the cost of the local authority, appointing such officer, inspector, or constable, or charged with the execution of this Act." Now, the authorities who appoint all these persons are, in counties, the Towns' Commissioners, the Boards of Guardians, and the Inspector-General of Police. Is it those authorities who are to appoint them to be Inspectors under the Sale of Food and Drugs Act, and pay them; or is it the Grand Juries? To make matters more unintelligible, section 26 directs that every penalty recovered by any officer, inspector, or constable of the authority who shall have appointed an analyst, shall be paid by him over to the authority for whom he acts. It is clear that the Grand Juries appoint the analysts, but it is equally clear that they do not appoint constables or inspectors of nuisances. I presume that the intention of the Legislature was, that the officers of the local authorities should act as inspectors, and that any expense which they incurred was to be defrayed by presentments made by the Grand Juries, as provided by section 29. At present, however, even the Local Government Board of Ireland are of opinion that the inspectors of the local authorities of counties can only act as private purchasers of food, and not as inspectors.
5. Under the 6th section of the Adulteration Prevention Act of 1872, the inspector could not only buy, but "procure" articles for analysis. This power enabled him to have the milk, &c., supplied to hospitals and other public institutions analysed, and, if found adulterated, the vendors thereof prosecuted. Now he cannot prosecute any person who has not sold to *him* (section 13), and to *his prejudice* (section 6), an adulterated article. As private persons rarely take the trouble of prosecuting adulterators, it would be desirable to restore to the inspector the power of "procuring" without buying articles for analysis which he formerly possessed. He should also have the power to purchase milk compulsorily from the persons who supply it from house to house; for section 17 of the recent Act only enables him to purchase articles in "any premises, or in any shops or stores."

Since the passing of the Sale of Food and Drugs Act, several prosecutions, instituted under its provisions, by the Inspectors of the Corporation of Dublin, have failed upon apparently trivial technical points. More than twenty prosecutions had to be abandoned because the inspectors had only offered a portion of the articles produced for analysis to the vendor, and had not offered to divide it there and then into three parts, as required by the Act. That is, when the vendor refused to receive back a portion of the article, the inspector thought it unnecessary to offer to divide the article into three parts. On this trifling point nearly all the cases of adulteration, first tried under the new Act, were either dismissed or withdrawn. I find that under a provision of the Dublin Improvement Act of 1849, any person who exposes, offers for sale, or sells any adulterated article, is liable on conviction to a penalty of £5. I am disposed to recommend that this simple-worded section of our Local Act should be taken advantage of (*a*) whenever the complicated provisions of the Sale of Food and Drugs Act had not been complied with by inspectors or private persons.

WATER ANALYSES.

Eight analyses of Dublin well water were made during the year; six proved to be impure and unfit for use. I also made four analyses of the water of the branch of the Dodder still used to supply some of the manufactories of Dublin with water, and found it polluted with refuse from a paper works. I attended at Tallaght Petty Sessions to give evidence against the owners of the paper works, but the case is still *sub judice*.

The will of Dr. Letheby, who died on the 28th March last, was proved on the 5th inst. by Mrs. Elizabeth Letheby, the widow, his sole executrix, the personal estate being sworn under 25,000*l*. The testator gives, devises, and bequeaths all the real and personal estate which he shall die possessed of to his wife.

(*a*) A prosecution has, since this report was read, been successfully sustained under this Act, and it will in future be frequently taken advantage of.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, MAY 31, 1876.

GENERAL MEDICAL COUNCIL.

On Wednesday last the General Medical Council commenced its meeting, deprived of four of the members who shared last year its deliberations. Of these four, two—Dr. Parkes and Dr. Begbie—have been removed by death, cut off in the prime of life, at an age when, after years of devotion to science, their experience was most valuable to the world. Two have retired—Dr. Sharpey, as the President remarked, the Nestor of Biological Science, to seek a well-earned repose, and Dr. Bennett, to apply his clear, calm judgment and assiduous services in another and a kindred sphere.

The four vacancies have been filled by Mr. Lister, Dr. Pitman, Mr. Simon, and Mr. Teale, whose election will give satisfaction throughout the profession.

From the address of the President, Dr. Acland, we learn what has taken place since the last sitting, and what matters have now to be discussed. The numerous topics which the Council has to consider little favour a supposition once entertained, and last year alluded to, viz., that its work would be almost ended when all the licensing bodies had been visited by inspectors and their reports had been received. It would be nearer the truth to say that when once the whole Council is satisfied that it can implicitly rely on the uniformity of a minimum standard in all the examinations, then there will be leisure calmly to study in detail the exact value of that standard and of the education to be tested by it. The Council will then be in a position to take a broad view of the relation in which the medical student of our day stands to modern wants, modern science, and modern division of labour.

We question whether the Council will ever be at a standstill for subjects to discuss. The whole system of examination and of education also will have to be revised. It has been said that reform has to go through three stages—first to be laughed at, second argued, and third resolved upon; but truly it may be said that medical education has not yet reached the laughing stage.

With regard to the percentage of medical men to the population, the President remarked that it had dropped from 9·7 in every 10,000 in 1851 to 7·8 in every 10,000 in 1871. In the army, 49 per 10,000 are required; it was becoming a matter of public concern, being difficult to supply the Army Medical Staff with competent practitioners.

It is questionable whether a much greater percentage than 1 medical man in 1,276 is requisite. Medical men, as a rule, have not more practice than they require until they arrive at middle or even old age; and we cannot quite agree with Dr. Farr that medical attendance for the people of England was extremely defective in 1851, and is still more defective in 1876, or that there is any danger that "it may grow quite inaccessible to vast numbers of people."

That medical attendance is at the present time inaccessible to some people is certainly the case, and must continue so to be, that is to say, so long as the people remain thinly scattered through extensive districts; but it does not follow that the supply of medical men is inadequate, or that the examinations are undesirably deterrent.

There is a large subject for the consideration of the Council in the question, "Are the methods of preparing for the examinations in any special manner inadequate, or are there any details of study enforced which have no direct relation with the clinical practice of the profession, or whether the secondary schools which our students attend do indeed give the best preparation for the medical life, whatever that may be." The question of how to ensure a test of a sound minimum education in each branch of the kingdom to be relied on not so much for its severity as for its wisdom, is expected to give rise to a sharp debate, springing from an unexcepted quarter.

Since the last meeting the Executive Committee have had placed before them questions "as to the registration of death certificates" and "as to Proficiencies in vaccination."

As regards the former, we commented last week on the report of the Registrar General that the unsatisfactory condition of the death register was mainly due to the employment of unqualified assistants by medical practitioners. If such is really the main cause of the unsatisfactory condition referred to, we apprehend but little difficulty in settling the question, but in this population where medical men are scarce and distant, and in dense and ignorant populations where parents are totally careless of the health of their children, there will be frequent deaths among those unattended by qualified medical men.

The second question as to proficiency in vaccination, was referred to a committee. It is a matter of some importance inasmuch as the Local Government Board refuse appointments on the ground that certificates as regards a knowledge of vaccination are not in conformity with the regulations of the Board.

Passing on to the Conjoint scheme, the President remarked that it must be a matter of regret to Sir James Paget, the assiduous chairman at the conferences, that all the bodies represented have not confirmed the conclusions of the majority of the delegates.

The Conjoint Scheme of 1874 not being cancelled still remains before the council, but in the new scheme no motion is before the council.

Two bills now before parliament will occupy an important place in the discussion of the Council. Mr. Gibsons bill which concerns the equality of qualification for certain offices in Ireland, and the registration of Public Health diplomas or certificates as an additional qualification.

The second Bill is one to be introduced by the Right Hon. Russell Gurney. The object of this bill is to *enable* existing Licensing Bodies to admit persons to examination without regard to sex.

There is no doubt that this bill will receive the support of the government should it be brought in but Mr. Cowper Temple's Bill upon which the Council expressed its opinion last year, and which has been received with marked disapprobation is not likely to meet with success.

It may be recollected that Mr. Cowper Temple's bill has for its object the admission of women to the Register, by making registerable foreign degrees obtained by women, and should it pass the *women's question* would be finally settled.

Mr. Russell Gurney's bill, if it should pass through parliament, may perhaps leave the question much as it now stands, inasmuch as it does not compel any licensing body to examine women, but only enables them so to do. It is however to be anticipated that after the expression of opinion by Parliament in favour of the admission of women to the register, the *dictum* may be cheerfully accepted by some who would not spontaneously promote it.

The Bill to prevent "cruel experiments on animals," introduced into the House by Lord Carnarvon, comes before the Council for consideration, and will be much altered through their deliberations.

The reports of visitors of examinations, and the observations upon those reports, by the several examining bodies raise important general questions.

THE GOVERNMENT VIVISECTION BILL.

In our last week's issue the space at our disposal did not permit us to do more than give a brief account of this Bill, and draw the attention of our readers to the somewhat objectionable tenor and wording of some of its clauses. The subject, however, is one in which the Profession have been all along far more deeply interested than even the general public. Ever since the agitation which was got up in opposition to vivisection, those who have been chiefly instrumental in promoting the movement and the more scientific members of the profession have been respectively in the position of plaintiffs and defendants. It is therefore not surprising that we should not only have felt some curiosity to learn the nature of the charges that have been brought against us, and the character of the testimony by which it was sought to substantiate those charges, but now that we have heard from the Government Commissioners the verdict—now that we have, as it were, been found guilty "with extenuating circumstances," it is only natural that we should be anxious to hear also and to pass our comment upon the sentence that has been passed.

Now it is evident that the "sentence" is one which is neither satisfactory to the opponents of vivisection nor to ourselves. When hasty legislation is conceded to popular and party clamour, it is seldom that such legislation is calculated either to remove the prejudices, meet the demands of public opinion, or to do justice to those whose delinquencies and practices were said to require the special interference of the Legislature. We must however admit that the Government had no easy task before it. On one side was a zealous and enthusiastic party clamouring for the total abolition of vivisection, and casting wholesale charges of cruelty, inhumanity, and unworthy motives against a learned and honourable class of professional men, while the latter on the other hand had little difficulty in vindicating their character, in justifying their practices, and in successfully pleading for liberty of action in the cause of that very humanity which they were accused of outraging. Nor was the task made more smooth by the verdict and recommendation of the Government Commissioners. They recommended vivisection to be controlled, but not to be abolished. But who does not know it is often more easy to completely suppress a thing than to control it? We know that the great aim of the Anti-Vivisection Society was to render illegal the practice of vivisection in any form and for any purpose whatever, and if the Government could have been prevailed upon to adopt such extreme measures we must, however strongly we might have condemned them, have admitted that there would then have been an end of the matter. Such an act would be very easy to work, its clauses would be few, and the wording of its clauses would be simple, and admit of no misconception. An act of suppression is thorough. It admits of no escape, of no exceptions, of no evasion. On the other hand, acts of toleration or control are inherently weak. They go too far or not far enough; they trespass too much upon personal freedom, upon vested interests, and the like, or they leave plenty of room for evasions and escape from the penalties attached to the transgressions of the law. While tolerating under certain restrictions, particular practices, they not only inferentially admit of their utility and the necessity of tolerating them, but, for this very reasons they are apt to miss in a great measure the object their authors have in view, and at the same time to put unnecessary restriction upon the practices to be controlled. Even the very concessions which the framers of such acts are in justice bound to make may create in the minds of unprejudiced persons a doubt as to the propriety of legislating on the subject at all, or to leave the impression that such legislation is, to say the least, premature.

With regard to the practice of vivisection in this country, we still think that immediate legislation on the subject was by no means so imperative as some have led the public to suppose, and that there are many other things which far more urgently claim the interference of Government than this practice does. To witness the fuss and excitement that have been made on this subject, one would naturally suppose that our medical schools had been the constant scene of the most revolting cruelty to the lower animals, and that a body of honourable and educated gentlemen must have become remarkably inhuman to necessitate their studies and scientific investigations being

placed under the meddlesome control of the Government. That the practice of vivisection has been in some instances abused we will not attempt to deny; but when we reflect that up to the present time vivisection has scarcely gained a footing in this country, that it would be practised by only those persons whose position in society, whose professional attainments, and whose devotion to science might preclude any probability of their giving more pain to the animals on which they experimented than could not be avoided, we cannot help coming to the conclusion that legislation on the subject is in many respects unnecessary and premature. Moreover, the Bill which is now passing through Parliament casts some reflection upon the profession, and questions the power or the willingness of its most prominent members to conduct their experiments in such a manner as humanity dictates, while its provisions are such as will hamper and embarrass the studies of those whose humanity is above suspicion, and who are best fitted and most anxious to add to our stock of scientific knowledge. It is even doubtful whether this Bill will satisfy that party which has been so loud in its outcry against vivisection, or whether the poor animals themselves will gain more by it than they would have gained had they been left to the mere influence of public opinion and to those humane feelings which, with rare exceptions, dwell in the breast of every gentleman of liberal education.

In our report of the proceedings of the General Medical Council it will be seen that we have given considerable space to the important debate on this Bill. The Council concur with us in thinking that the provisions of the Bill go far beyond "the bounds dictated by humanity." Some of its clauses go even beyond the recommendations of the Commissioners. It is impossible that the Medical Council, charged as it is by law with the duty of superintending the course of medical studies in this country, can be a party to legislation which must lead to evasion and secrecy, or banish physiological teaching and research altogether from our schools. At the suggestion of Professor Lister a committee was appointed to consider the various clauses of the Bill. At the outset, however, the Council declare that they "are not aware that in regard to experiments on animals such abuses have existed in Great Britain as to justify exceptional legislation, restriction of physiological study and research. Nevertheless, they would be glad to assist the Government in passing a measure that may give all reasonable securities against any possible abuse." This seems reasonable enough, but from what transpired in the House of Lords on the second reading of the Bill and elsewhere during the past week, it seems that those who are determined to have abolition will not be satisfied with a moderate measure. The Duke of Somerset very properly said in his speech objecting to the Bill as it now stands, that it seemed to him to take in every animal, from an elephant to the smallest creature that could be put under the microscope; it created also a new definition of cruelty, while it freely permitted the infliction of pain on animals in more objectionable ways; for it cannot be denied that "a single day's rabbit shooting would inflict more pain than scientific men in a whole year of physiological experiments. Furthermore, pain was daily inflicted on animals for purposes of amusement, curiosity, and vanity: birds were killed that they might be worn in ladies' bonnets; they had the Arctic regions ransacked for their seal-skins, and then we are told they were so humane that they could not bear the idea of infliction of pain upon animals." Numerous instances were adduced by the Duke of unnecessary cruelty inflicted upon animals as the "firing" of horses, the castration of lambs, the spaying of sows, the slow and protracted death of the calf, and not for the benefit of the animal but simply to make it better for culinary purposes. With the latter object many thousands of animals are cruelly mutilated and subjected to a torturing death solely for the gratification of the palate; but this, the advocates of the Bill say, justifies the infliction of any amount of pain and removes it from the catagory of "cruel experiments by scientific men." It is utterly useless to reason with people whose feelings are so perverted that they will not see that experimental physiology has for its purpose the sole object of prolonging *human life* and *mitigating human suffering*. The Duke of Somerset's muscular Christianity evidently ill suits such people and their champion the *Spectator*, whose columns aid and abet "wantonly-libellous" statements on the medical profession, and readily excuse those who inflict cruelty in sport and simply to suit the appetite. The Editor cantingly writes: It is no doubt thoughtless and careless of society to sanction these things, and in taking precautions that painful processes should not be inefficiently and blunderingly performed; yet these applications of painful means to *useful ends are certainly justifiable!* Such arguments but too plainly show to what lengths some people will go on this vexed question, for while advocating humane feelings towards dogs and cats, they completely set aside all consideration for *human beings*. Truth is made to appear false, and falsehood furbished up in support of a bad cause, as occasion may require. The Earl of Carnarvon, on Monday night, did not scruple, and upon insufficient data, to hold up Dr. Klein to public reprobation for his indifference to the sufferings of animals, and, as others have done before, garbled the evidence of this "eminent physiologist from Vienna," for he skilfully concealed what Klein most emphatically stated in his evidence before the Commissioners, that no pain was inflicted in his experiments on animals, and therefore no anæsthetic was either given or required. Lord Carnarvon cannot understand this fact, because he has no practical acquaintance with the subject upon which he is so anxious to legislate; and he did not hesitate to ask their lordships "to concur with him in thinking that such an expression (as that given by Dr. Klein) was detestable." Another eminent Professor—Huxley—has been so repeatedly misrepresented that he is at last goaded into addressing the Editor of the *Times*, and gives the most complete denial to the statements made by Lord Shaftesbury, that he had given encouragement to vivisection. He writes:—"If Lord Shaftesbury had the slightest theoretical or practical acquaintance with the subject, he would know that physiological anatomy is not exactly the same thing as experimental physiology, and he would be aware that the recommendation of the paragraph quoted might be duly carried into effect without the performance of even a solitary vivisection." But this is just what the most active agitators in this

matter lack; they have neither a theoretical nor a practical knowledge of physiological teaching or experiments, and they know not what they ask or wish. It must, however, be clear to those who have the requisite knowledge that the suggestions of the Medical Council for amending the Bill are absolutely needed, and must be carefully brought to the notice and more matured judgment of the Government, otherwise it will be found to be impossible to teach physiology. To point to one or two blots, the effect of clause 3, as it stands in the Bill, will be to banish teaching to Continental schools. The attempt to limit all experiments to registered places would grievously obstruct independent inquiry, and prove impossible in practice. Licensed persons would be subjected to the most un-English form of espionage if the abettors of the Bill are to have their way, for it is now proposed to make the penal clause of the Bill more stringent and inquisitorial, by giving power to arrest any one suspected of offending against the Act." The reason stated for asking for additional powers in this respect is that, "in the event of offenders refusing to give their names and addresses," the officers of the Society for the Suppression of Cruelty to Animals should have power to enter a gentleman's house and search for evidence for his conviction. Can anything be more monstrous than such a proposal? We commend the amendments of the Council to the serious attention of Parliament.

THE SCIENTIFIC ASPECTS OF HANGING.

SINCE the communication of the Reverend Professor Haughton to the Surgical Society of Ireland on this subject appeared in the pages of the MEDICAL PRESS much interest has been excited in America and on the Continent as to the pathology of hanging, and investigations have been made as to the cause of death. We published lately a report of a post-mortem examination upon the body of a man hanged at Hamilton, in Canada, which completely corroborated Professor Haughton's views as to the fracture of the cervical column being effected by the submental knot and the long drop. In the *Allg. Wien. Med. Zeitung* of the 4th of April there appears also as article from the pen of Professor Hoffman, of which we append an abstract.

By way of introduction the essayist touches on the various kinds of death by suffocation, and then proceeds to the consideration of death by hanging. He expounds separately the views that have been till now current in various places, adding explanatory examples to each, in order to bring more cleorly into view the arguments *pro* and *con.*, and finally comes to the conclusion that death by hanging is not brought about by the stoppage of the air-passages *solely*, or even *mainly*. To illustrate and establish his proposition he has used four preparations, the first of which is the skull of an executed criminal sawn asunder sagittally; the second is got from a corpse that had been suspended for the experiment, and had become rigid in this position by cold; the third is a skull injected with a plastic substanbe; and, lastly, the fourth comprises all the soft parts of a corpse, from the jugulum to the cavity of the jaw (including the tongue); the corpse had been suspended, and into both carotids had been injected, first potassi ferrocyanide (K_4 Fe Cy_6), and then a solution of ferric chloride (Fe Cl_3). From these four preparations we can see (1) that the air-passages are closed, but in a different manner from that hitherto supposed, and (2) that the carotids are compressed to *absolute impassibili y* (shown especially in the fourth preparation). The stoppage of the air-passages is produced by the root of the tongue on one side, and by the soft palate with the uvula on the other. These bodies are prcssd by the halter against each other and against the vertebral column with the weight of the whole body, and in this manner their orifice is closed. It was formerly held that the stoppage of the air-passages was a condition of death. But a few years ago Prof. Jendrassik, of Pesth, showed us that this is not at all the case. He had a pupil with a certain facility of compressing with his finger his vagus on one side, and on one occasion had requested him to compress the vagus on both sides at the same time; scarcely had his hands, however, properly laid hold of his neck when the young man became at once cyanotic, and fell off his seat, still, however, holding on convulsively to his neck, so that Jendrassik had even to remove his hand by force from its place, and to induce the respiratory motions by the ordinary measures of re-animation. Meanwhile the larynx was unimpeded.

That the closing of the air-passages cannot be the *main* cause of death is shown further by the fact that we can hold our breath for periods of even longer than half-a-minute without becoming unconscious, and falling from our seat. According to the statements of the few individuals who have been respited from hanging, we know that between the moment of tying the halter and the loss of conscious ness there is only an extremely short interval. Judging from their experiences, the cause of the rapid disappearance of consciousness must be sought elsewhere, since a fracture or luxation of the alveolar process in death by hanging has been rarely found, and even in the case of executed persons is certainly far rarer than is supposed.

My experiments go to prove that that cause is to be found in the stoppage of the blood-passage to and from the brain, and in the compression of the vagi. This view is also supported by the case quoted by Taylor in his work on medical jurisprudence :—"An enterprising American gave 'representations' in hanging, in which he hanged himself, coram publico, and after remaining suspended a few moments got down again from the gallows. Once, however, he committed some blunder, or neglected some or other precaution, and effectually hanged himself till he was dead." This case shows that unconsciousness must supervene faster than we had hitherto supposed, for otherwise the man would certainly have asked for assistance. Hence is explained why nobody who had chosen this mode of suicide ever desisted from his design when once begun; it was impossible, as consciousness at once failed. Death by hanging, therefore, takes place mainly by the interruption of the passage of blood to the brain, and the stoppage of the air passages is only of secondary importance.

It will be observed that Professor Hoffman has not directed his attentionto the cause of death when the long drop is used, or to the conditions which produce vertebral dislocation; but he has proved that, when a simple constriction of the neck is produced, death is caused, not by asphyxia, but by compression of the pneumogastrics, and

stoppage of the cerebral blood supply. The observation which he makes that "it is thus explained why nobody who had chosen this mode of suicide ever desisted from his design when once begun; it was impossible, as consciousness at once failed," is worthy of the attention of medical jurists who have hitherto assumed that suicide under such circumstances was an evidence of strong determination and intentional self-destruction.

Dr. Haughton has also received a letter from Dr. Hanby, of Oceola, in the United States, who, in the year 1871, had advocated the use of the submental knot. Dr. Hanby, however, produces the cubical fracture not by the impetus of the falling body, but by lifting the body suddenly four or six inches, by the sudden chuck of a disengaged weight suspended by a perfectly inelastic cord. Whether this method has any advantage over the long drop remains for experience to prove.

Notes on Current Topics.

The Debate on Vivisection.

THE debate in the Medical Council, which consumed nearly the whole of Saturday and Monday, will rank amongst the most able that has ever occurred since the constitution of that august body. Attracted probably by the interest of the subject and the expectation that it would produce some powerful speeches, a considerable sprinkling of visitors dropped in, amongst whom were noticed Professors Donders of Utrich, Bowman of London, Mr. Samuel Morley, M.P., and others. This interest was well repaid, whether viewed in the light of admiration eloquence always commands, or for the valuable and interesting facts and opinions embodied therein. Sir Dominic Corrigan enlivened the proceedings, as is his wont, with occasional flashes of Irish wit, and the debate on the whole may be characterised as a feature in the history of the Medical Council.

Composition of the Medical Council.

GLANCING round the table at the opening of the session on Wednesday, we were forciby struck with the changes the last few years have wrought in its composition. Of the English members but one of the original representatives now holds a seat, in the person of Dr. Storrar. Of the Scotch representatives but one remains—viz., Dr. Andrew Wood. Ireland is more fortunate; with the exception of the representative of the College of Surgeons, she is still served by the same members as on the first composition of the Council. Since last year four new faces appear—a fact, alas! that sorrowfully reminds us of the great loss not only the Council, but the whole profession have sustained in the recent deaths of Drs. Parkes and Begbie.

Curiosities of the Anti-Vivisectionists.

IN the debate which occupied the attention of the Medical Council nearly the whole of Saturday and Monday, and from which a series of resolutions were drawn up for presention to her Majesty's most honourable Privy Council, some curiosities were brought to light which, but for their seriousness, would be highly amusing. We firmly believe that the agita tion, amounting almost to a panic on the part of the public, is an evidence of *bonâ fide* intentions and humane feelings; but is it not, we ask, another instance of "the blind leading the blind," with a ditch before them into whose depths they will sadly regret having fallen? Do the public take the trouble to think of the torture they inflict daily upon fish, flesh, and fowl, for their own enjoyment, without the reasonable excuse of furthering the progress of science? Is it consistent with their humane protestations to boil lobsters and crabs and shrimps alive, to skin eels, and to crimp the throbbing flesh of salmon and skate? What of the physical and mental suffering of the fox and hare after a day's hunting, worrying, and final killing by the dogs?—the winging of pheasants and other birds which struggle to their nests, there to linger in terrible agony for days and to die? Do these and a thousand other acts of torture ever occur to their sensitive minds as they gloat over recollections of what *they* call sport? Yet men of science are to be branded with infamy and to be taught, as Sir Wm. Gull said, two hundred and forty years after the discovery by the immortal Harvey of the circulation of the blood, that physiological experiment is not necessary. How but by experimentation upon the lower animals would the action of drugs to alleviate pain and to cure disease be discovered? Would the public prefer these tests in their own persons? Truly the grossest cruelty is that of ignorance!

Complimentary Dinner to Surgeon-General Sir Joseph Fayrer.

THE complimentary dinner given by the officers of the Indian Medical Service to Sir Joseph Fayrer came off on Wednesday last, the Queen's birthday, at St. James's Hall. The chair was occupied by Dr. Forsyth, C.B, Inspector-General retired, one of the oldest and staunchest friends of Sir Joseph Fayrer, who was well supported by members of the service. The event was one demanding our hearty congratulations, and the kind and cordial feeling exhibited towards the guest of the evening must have been extremely gratifying. After the usual loyal toasts were given and disposed of, General Alexander returning thanks for the army, and Sir Alexander Armstrong for the navy, the Chairman in feeling and appropirate terms proposed the health of Sir Joseph Fayrer, who on rising to return thanks was received with enthusiastic applause. Dwelling for a moment on the great pleasure it afforded him to find himself surrounded by so many friends, he proceeded to give a rapid sketch of the Prince's tour—the pleasures, the difficulties, and the dangers with which it had been attended. His anxieties were not a little increased on finding it necessary to recommend an alteration in the arrangements for an extension of the journey to Southern India, where cholera then prevailed. His responsibilities were, however, lightened by the kind and efficient aid he at all times received from his brethren of the service.

Professor Maclean then gave the "Guests of the evening," associating with the toast the names of Surgeon-General Mouat, C.B., for the British service, and Mr. Geo. Pollock for the rest of the visitors. The health of Lady Fayrer, proposed by Dr. F. Mouat, brought the proceedings to a close.

The success which attended the gathering was in no

small degree due to the admirable arrangements of the Hon. Secretary, Dr. Baillie. Amongst the company present we noticed Deputy Surgeon-General Mackinnon, C.B., Dr. Jackson, Dr. Eatwell, Dr. Aitken, Professor Longmore, Dr. Sutherland, Dr. J. Macpherson, Dr. Waring, Surgeon-General F. Innes, C.B., Dr. Leckie, Dr. Baycott, Surgeon-General Cox, Dr. Hugh Macpherson, Dr. Bashham, Mr. Macnamara, Mr. Jabez Hogg, Dr. Playfair, Dr. Lauder Brunton, Surgeon-Major Paul, Dr. Ogg, Dr. Lethbridge, &c.

Medical Women.

THE University of Zurich has during the last ten years conferred the degree of Doctor upon thirteen ladies who have completed their studies in the faculty of medicine of the University, two others have taken the degree of Doctor of Philosophy, and three have obtained the diploma qualifying them as teachers of science. In announcing to the last female medical graduate, Miss Julia Sinclair, her success in the examination, M. Hermann remarked that those who like him regarded the problem of a medical career for women as by no means yet decided could not withhold their approbation of the manner in which the examinations had been passed. They had from the first fought against the ignorant prejudice which declared the female sex incapable of serious study of scientific work, and the theory was amply refuted by the original and excellent theses presented by the graduates.

Dublin Water Supply—Filtration.

A CIRCUMSTANCE occurred last week which is significant of the value which the Dublin citizens derive from the filtration arrangements of their water supply. The house of a medical gentleman residing in the centre of the city was suddenly deprived of its supply of water, to the great inconvenience of the inmates. Inquiring from his next door neighbours, he learned that they both enjoyed their usual supply, and he therefore sent off for the officials of the waterworks department, who, after much cogitation, failed to elucidate the cause of the stoppage. *Faute de mieux*, the street was opened and the pipe taken up, when a large eel was found wedged head foremost in the pipe. When the citizens of Dublin received their water supply from the canals, they were told that if they consented to pay for the new Vartry supply, they would no longer suffer from the incursions of animals into their cisterns. What better are they now?

Lord Carnarvon's Bill.

WE presume the expression of the views in the Medical Council on Saturday last have had some weight with her Majesty's Government; the announcement in the House of Lords last evening, by the Duke of Richmond and Gordon that he did not intend to ask their lordships to proceed with the Cruelty to Animals Bill until after Whitsuntide, as he had received several communications of an important character in relation to this bill, from persons who took a great interest in the subject, may be put down to the energetic action of the Medical Council

The Approaching Medical Congress at Philadelphia.

THE Congress will meet on Monday, September 4th, 1876, in the University of Pennsylvania. The following addresses will be delivered in general meeting:—On Medicine, by Professor Austin Flint. On Hygiene and Preventive Medicine, by Henry I. Bowditch, M.D., of Massachusetts. On Surgery, by Professor Paul Eve, of Nashville. On Obstetrics, by Professor Parvin, of Indiana. On Medical Chemistry and Toxicology, by Professor Wormley, M.D., of Columbus. On Medical Biography, by J. M. Toner, M.D., of Washington. Address, by Professor Hermann Lebert, of the University of Breslau. On Medical Education and Medical Institutions, by Professor Nathan Davis, of Chicago. On Medical Literature, by Professor Yandell, of Louisville. On Mental Hygiene, by John P. Gray, M.D., of Utica. On Medical Jurisprudence, by Professor Chaillé, New Orleans. Discussions on Scientific Subjects will be opened in the sections as follows:—

SECTION I. MEDICINE.—Typho-malarial Fever: is it a Special Type of Fever? J. J. Woodward, M.D. Are Diphtheritic and Pseudo-membranous Croup Identical or Distinct Affections? J. Lewis Smith, M.D., of New York. Do the Conditions of Modern Life favour specially the Development of Nervous Diseases? Professor Bartholow, Ohio. The Influence of High Altitudes on the Progress of Phthisis. Charles Denison, M.D., of Denver.

SECTION II. BIOLOGY. Microscopy of the Blood. Professor Johnston, of Baltimore. The Excretory Function of the Liver. Professor Austin Flint, Jr., of New York. Pathological Histology of Cancer. Professor Arnold, of New York. The Mechanism of Joints. Professor Allen, of Philadelphia.

SECTION III. SURGERY.—Antiseptic Surgery. Professor Hodgen, of St. Louis. Medical and Surgical Treatment of Aneurism. Professor Van Buren, of New York. Treatment of Coxaglia. Professor Sayre, of New York. The Causes and Geographical Distribution of Calculous Diseases. Claudius H. Mastin, of Mobile.

SECTION IV. DERMATOLOGY AND SYPHILOLOGY.—Variations in Type and in Prevalence of Diseases of the Skin in Different Countries of Equal Civilization. Professor White, of Boston. Are Eczema and Psoriasis Local Diseases, or are they Manifestations of Constitutional Disorders? Lucius Duncan Bulkley, M.D., of New York. The Virus of Venereal Sores; its Unity or Duality. Professor Bumstead, M.D., of New York. The Treatment of Syphilis, with Special Reference to the Constitutional Remedies appropriate to its Various Stages; the Duration of their Use, and the Question of their Continuous or Intermittent Employment. Professor Keyes, M.D., of New York.

SECTION V. OBSTETRICS.—The Causes and the Treatment of Non-puerperal Hæmorrhages of the Womb. Professor Byford, M.D., of Chicago. The Mechanism of Natural and of Artificial Labour in Narrow Pelves. Professor Goodell, M.D., of Philadelphia. The Treatment of Fibroid Tumours of the Uterus. Washington L. Atlee, M.D., of Philadelphia. The Nature, Causes, and Prevention of Puerperal Fever. Professor Lusk, M.D., of New York.

SECTION VI. OPHTHALMOLOGY. — The Comparative Value of Caustics and Astringents in the Treatment of Diseases of the Conjunctiva, and the Best Mode of Applying them. Professor Williams, of Boston. Tumours of the Optic Nerve. Hermann Knapp, M.D., of New York. Orbital Aneurismal Disease and Pulsating Exophthalmia; their Diagnosis and Treatment. Professor E. Williams, M.D., of Cincinati. Are Progressive Myopia and Posterior Staphyloma due to Hereditary Predisposition, or can

they be induced by Defects of Refraction, acting through the Influence of the Ciliary Muscle? E. G. Loring, M.D., of New York.

SECTION VII. OTOLOGY.—Importance of Treatment of Aural Diseases in their Early Stages, especially when arising from the Exanthemata. Albert H. Buck, M.D., of New York. What is the Best Mode of Uniform Measurement of Hearing? Clarence J. Blake, M.D., of Boston. In What Percentage of Cases do Artificial Drum-membranes Prove of Practical Advantage? H. N. Spencer, M.D., of St. Louis

SECTION VIII. SANITARY SCIENCE.—Disposal and Utilization of Sewage and Refuse. John H. Rauch, M.D., of Chicago. Hospital Construction and Ventilation. Professor Smith, M.D., of New York. The General Subject of Quarantine, with Particular Reference to Cholera and Yellow Fever. J. M. Woodworth, M.D., Supervising Surgeon-General. The Present Condition of the Evidence concerning "Disease-Germs." Thomas E. Satterthwaite, M.D., of New York.

SECTION IX. MENTAL DISEASES.—The Microscopical Study of the Brain. Walter H. Kempster, M.D., of Oshkosh. Responsibility of the Insane for Criminal Acts. Mac Ray, M.D., of Philadelphia. Simulation of Insanity by the Insane. C. H. Hughes, M.D., of St. Louis. The Best Provision for the Chronic Insane. C. H. Nichols, M.D., of Washington, D. C.

Gentlemen intending to make communications upon scientific subjects, or to participate in any of the debates, will please notify the Commission before the first of August.

The public dinner of the Congress will be given on Thursday, September 7th, at 6·30 p.m.

The registration fee will not be required from foreign members.

There is every reason to believe that there will be ample hotel accommodations, at reasonable rates, for all strangers visiting Philadelphia in 1876. Further information may be obtained by addressing Corresponding Secretaries.

All communications must be addressed to Richard J. Dunglison, M.D., 814 North 16th Street; R. M. Bertolet, M.D., 113 South Broad Street, Foreign Corresponding Secretaries.

Admission of Women to the Register.

WE are inclined to believe that the Medical Council will advise the Government not to accept Mr. Russell Gurney's Bill, which is intended to enable Examining Bodies to admit to examination all persons without distinction of sex, but to pass an Act which shall enable the Medical Council to recognise examination or examinations which shall admit women to the Register under the title of Licensed Practitioner of Medicine.

Procuring Abortion.

AT Leicester, last week, Cornelius Asker, herbalist, seventy-six years of age, was charged with the wilful murder of Ann Gee, on the 2nd inst. Deceased, a married woman, aged twenty-six, whose husband is in America, visited prisoner's shop on the 24th ult., and was immediately afterwards taken ill, and lingered in great pain until the day of her death. After the burial the body was exhumed, by order of the coroner, and a *post-mortem* examination revealed the fact that there were several punctures of the uterus, caused by the use of instruments similar to some found on prisoner's premises. Prisoner, who is said to have been sentenced to fourteen years' penal servitude for a similar offence in 1855, and to have been released on a ticket-of-leave, was remanded.

Adulteration Prosecution of Wholesale Dealers.

THE first case with which we are conversant, in which a wholesale dealer has been made liable, upon his warranty, for an adulteration, occurred at Bradford last week. A dairyman was prosecuted for selling adulterated milk. He pleaded that the article was as he bought it from the wholesale dealer, produced an agreement from the latter engaging to supply "genuine pure milk," and claimed exemption from the penalty under the saving clause of the Sale of Food and Drugs Act. After a lengthened argument the magistrates held that the warranty was good in law, and accordingly dismissed the charge against the retailer, and inflicted a fine of £10 and costs, or a penalty of two months' imprisonment on the wholesole dealer. We trust that this case will afford an inducement to the retailers of all articles which are liable to adulteration to protect themselves by obtaining a warranty or an invoice which sets out explicitly the nature of the article purchased.

The Royal Medical Benevolent College.

THE annual general meeting of the Medical Benevolent College took place on Thursday last, at the rooms of the College, Soho Square. Dr. Jonson occupied the chair. The report of the council assures us that the institution is in a sound and satisfactory condition; the bi-annual aniversaryn dinner, under the presidency of the Earl of Egmont, produced a considerable sum. The present state of the school is all that can be wished—educationally successful—several of the pupils of the past year having competed for and gained scholarships at one or other of the Universities. Frederick Baylis, one of the pupils, was elected to a Junior Studenship in Natural Science at Christ Church, Oxford; another, Arthur Cutfield, gained by open competition two Natural Science Scholarships at Cambridge, both boys having matriculated at the London University in honours, one being placed first and the other third on the list. The resignation of the treasurer, Mr. Hancock, formed a subject of regret; but, as the Chairman remarked, even this cloud had its "silver lining," for Mr. Hird, an old and staunch supporter of the College, had consented to fill his place.

The report dwelt at some length on questions raised by a large body of memorialists as to the mode of election to scholarships and pensionships; and it was stated with considerable satisfaction that the abolition of the public polling-day, as well as compelling all candidates to send in their votes to the Secretary of the College, had removed a scandal, and been a means of saving time and trouble to all parties concerned. The Council, however, after mature deliberation, could not see its way to abolishing the voting, and which the Act of Incorporation conferred upon all subscribers. It was feared too, that an attempt to interfere with this right might have a disasterous effect upon the funds of the College. It appeared equally impossible to the Council to make any recommendation of the comparative urgency of the claims of candidates, or to appoint a committee of selection, as this would probably give offence and subject the members of such a committee to the charge of favouritism and undue influence. It was, nevertheless, urged by gentlemen present, who spoke on behalf of the memorialists, that further consideration should be given to

the question, and that if the Council could not see their way to the abolition of the voting system, they could at least go further in the direction of reforming abuses which have gathered round it, and prevent as far as possible the infliction of injury on candidates.

Deputation to the Home Secretary on the Vivisection Bill.

THE Parliamentary Bills Committee of the British Medical Association met on Saturday, and agreed to a report nearly identical to that agreed to by the Medical Council. On Monday a deputation (Mr. Hart, the chairman, Dr. Rutherford, Dr. Pye Smith, and Dr. Mackendrick) had an interview with the Home Secretary, and urged upon him

1. To extend the enumeration of the objects of research so as to include all medical and physiological investigation.

2. To withdraw clause 5, which prohibits experiments on dog or cat.

3. To introduce a clause permitting vivisection under special certificate in places not registered.

4. To withdraw the offensive clause which refers to police investigation.

Mr. Cross was of opinion that there was a strong feeling in the House in favour of complete prohibition of vivisection, but he thought the clause relating to dogs and cats might be modified, and that licences should be easily obtainable by the signature of a professor or lecturer at any recognised medical school; also that the police clause could be withdrawn.

The Irish Science Amalgamation Scheme.

AT a meeting of the Royal Irish Academy, held last week, a report of the Council was read, containing resolutions to the effect that the Council, by a large majority, objected to the proposed amalgamation of the Academy with the Royal Dublin Society, and unanimously objected to the proposed transfer of the vote for the Academy from the Treasury to the Science and Art Department.

Successful Prosecution under the Medical Act.

AT Carnarvon, a few days ago, a man named Owen was summoned, under the 40th section of the Medical Act, for having "unlawfully, wilfully, and falsely used the name of a surgeon." Prosecutor said that the defendant had for three months been in the service of a local surgeon. Although not a qualified man, he had since started a practice. On May 3, a certificate of the death of a child, signed "R. J. Owen, surgeon," was given to the district registrar of births and deaths, and upon that misrepresentation the present proceedings were taken. Mr. C. A. Jones, on behalf of the defendant, contended that there had been no wilful misrepresentation, the defendant having used the title "surgeon" as a matter of courtesy. A fine of £5 and costs was imposed, and the bench declined to grant a case.

THE vacancy created in the staff of the Middlesex Hospital by the retirement of Dr. Liveing has been filled by Dr. Cayley. Dr. Sidney Coupland succeeds Dr. Cayley as assistant-physician.

WE understand that a case of death from sloughing of the tongue and abscesses in the jaw, with complete prostration, has occurred in Dublin, as a sequela of the administration of two pills, each containing two grains of blue pill.

THE annual festival dinner of the Metropolitan Free Hospital was held last week at the London Tavern, Sir Charles Mills, Bart., in the chair. The munificent sum of £2000 was subscribed in the room.

SEVENTEEN more deaths occurred last week from small-pox in Manchester and Salford, raising the number of fatal cases there recorded since the beginning of the year to 198, exclusive of those occurring in the Monsall Hospital, situated outside the municipal boundaries of the city of Manchester.

THE annual dinner of the Poplar Hospital for Accidents was given last week, under the presidency of Mr. Samuda, M.P. This hospital is situated in a densely populated district, near the London Docks, where it plays a most useful and humane part. The Chairman made a very earnest appeal for funds, and succeeded in drawing about £1,600 from the pockets of his hearers.

WE hear with considerable apprehension that the plague is gradually extending and advancing. The *Levant Herald* of the latest date says "The plague has spread to several localities between the Tigris and Euphrates to the south of Hillah. From the 30th March to the 6th April inclusive the plague had been slightly more fatal at Bagdad than during the previous week, there having been 409 deaths, or an average of about 59 per day."

ON Saturday evening the anniversary festival in aid of the funds of St. Mary's Hospital, Paddington, was held at Willis's Rooms, Viscount Enfield in the chair. During the year 1875, 14,376 persons have been treated, including in-patients, out-patients, and casualties. The chairman strongly appealed for funds, which was answered by donations to the amount of about 600*l*.

THE anniversary festival of the London Temperance Hospital was held at the Memorial Hall on Monday evening, Sir Wm. King Hall presiding. It was stated that 10,119*l*. had been promised in aid of the new building. During the year it had been found necessary to administer alcohol in any of the cases treated; the mortality had been exceptionally low.

THE SURGEON-OCULIST TO THE QUEEN IN IRELAND.

THE recent appointment of a surgeon-oculist to the Queen, seems to have been regarded with almost universal disfavour. Of the daily organs of public opinion in Dublin, the *Express* and *Saunder's News-Letter* give utterance to a high opinion of Dr. Fitzgerald's personal qualities which is well deserved, the latter however entering into a lengthened apology for the appointment. "Amongst four eminent oculists of nearly equal merit"

it says, "it should not be a matter of surprise or an occasion for reproach that her Majesty's advisers should have selected the gentleman who, in the opinion of the best English oculists, was the most deserving of the honour.' We believe ourselves entitled to say that no English oculists—the best or the worst—have expressed any opinion on the subject, simply because the voice of the profession, both in England and Ireland, has been entirely ignored, and no opportunity has been afforded to anyone to testify to the qualities of any of the surgeons named for the distinction. With the exception of these two journals the opinion of the press has been unanimously condemnatory.

The *Irish Times* says :—

There were two most distinguished oculists candidates for the post, and it was the firm belief of the medical profession that the office would have been given either to Dr. Wilson or Dr. Jacob. One of these gentlemen had performed the active duties of the late Sir William Wilde's Eye Infirmary for many years ; the other's name, as well as his own reputation as an oculist, made him a formidable rival. The dignity has been conferred on a young physician respecting whose skill or experience as an oculist we have heard nothing. We shall be only too happy to recount his claims to the position when we know them.

The *Freeman's Journal* says :—" Mr. Fitzgerald is a young gentleman of marked ability, growing reputation, and unexceptionable character, against whom personally nothing whatever can be urged. But we deeply regret the appointment as one by which gross injustice has been done and an evil precedent set. Both public and professional opinion had named two gentlemen, on one or other of whom it was thought the post in question would be conferred. These gentlemen were Dr. Jacob and Dr. Wilson. Both men have been over sixteen years in practice as ophthalmic surgeons, lead their profession in Dublin, hold many important public appointments, and enjoy a high, general, and well-earned reputation. We have not a word to say against this talented young gentleman, but certainly the 'blue ribbon' of the profession should have been conferred on proved ability, not on rising merit."

Our medical contemporaries refer very briefly to the appointment. The *Lancet* says—"The appointment appears to have caused some amount of dissatisfaction amongst part of the profession in the Irish capital, who are of opinion that there are ophthalmic surgeons who had greater claims for the distinction than Dr. Fitzgerald."

The *Medical Times and Gazette* observes that the selection of Dr. Fitzgerald has caused some surprise in Dublin, as he is a very young man, having been qualified only since 1868. And the *British Medical Journal* expresses no opinion, but simply states that Mr. Fitzgerald is the Junior of the four candidates for that honour, whose names have been mentioned.

We have authority for stating that neither the Surgeon-Oculist to the Queen in England—nor any of her Majesty's Surgeons in Ireland, nor His Grace the Lord Lieutenant, were consulted on the matter.

Desquamative Scarlatiniform Erythema.

At a recent meeting of the Société des Hôpitaux (*Bull. Gén. de Thérap.*, February 15) M. Féréol presented a patient, a young man affected with exfoliative dermatitis presenting peculiar characters. Two years ago, after some typhoid symptoms, he was attacked by a scarlatiniform eruption of a peculiar nature. He recovered from this, and remained fifteen to eighteen months without further trouble. Last year these same symptoms appeared once more, but this time without having been preceded by fever. At this time desquamation of the whole of the integument took place. Since then (January, 1875) this pseudo-exanthem recurred seven times, always under the same conditions, that is to say, preceded by a slight angina, with a slight febrile movement or even without fever. Finally, these relapses have become, so to speak, incessant. The desquamation, always entire, commences in the superior portions of the body, and terminates at the feet. The patient's general condition is fair, his appetite is good, and there is nothing abnormal in the urine.

M. Féréol asked the members of the Society their opinion, of the case as to diagnosis and treatment.

M. Blachez had observed a similar case long ago. No precise diagnosis had been made. Some thought it to belong to the class of eczemas ; others regarded it as a pemphigus. The case was also that of a young man, whose body, little by little, became the seat of such an abundant desquamation that not less than one to one and a-half litres of epithelial *débris* was collected from his bed every morning. The desquamation was accompanied by acute pain. For six months the patient remained in this condition, without gaining any relief from treatment. The carron-oil dressing alone seemed to relieve the local symptoms. Among other symptoms in this patient, the nails became the seat of a secretion from their internal surface, so as to form a sort of pad of epithelium, separating the nail from the subjacent parts. The sense of taste was completely abolished ; the tongue was entirely deprived of papillæ. The general health continued good, excepting that some slight fever was observed from time to time. The patient was afterwards attacked by furuncles, and even anthrax, and finally succumbed to pneumonia.

M. Blachez laid stress upon the point that in this case the affection was continuous, and only presented some exacerbations. It should be observed, also, that it was perfectly rebellious to treatment.

M. Besnier thought the term *dermatitis* one much abused, and suggested the name *desquamative scarlatiniform erythema* for cases like the one under consideration.

NOTES FROM OUR AMERICAN EXCHANGES.

Cerebral Syphilis.

Professor H. C. Wood (*Philadelphia Med. Times*), in answer to the question—" What ought to be the treatment of an acute attack of cerebral syphilis ?" says that it should be very much that of an acute, non-specific, cerebral attack of a similar type. If there be violent epilepsy, with the epileptic status, nitrate of amyl, anæsthetics, antispasmodics, and other usual remedies should be employed. If the pulse, the fever, the *tout ensemble* of the symptoms indicate intense cerebral congestion, or cerebritis, free venesection should be used. Violent specific meningitis should receive the same treatment as non-specific disorder, *i.e.*, bleeding, local and general, blistering, and mercury. He quotes an interesting case that came under the care and observation of Dr. Frecke, in which a man, the subject of syphilis, becames semi-unconscious, and was seized with severe convulsions and delirium. The convulsions were tetanic and clonic, and the patient raved furiously. Ordinary remedies failing, fifty ounces of blood were taken from the arm with immediate relief ; slight twitchings recurring about the face, an additional pint was taken by means of cupping from the temples. The patient became as quiet and relaxed as a sleeping infant, and awoke next day, weak, but free from pain, and out of danger. Subsequently an anti-syphilitic course of treatment completely restored this patient to health.

Professor Wood favours the use of large doses of iodide of potassium ; commencing with a drachm a day in divided doses of gr. xv., he increases it up to two drachms, or even three where well borne, until iodism is produced.

Where the syphilitic cachexia is absent, and there is no other contra-indication to the use of mercury, he is strongly in favour of it, believing its action to be highly beneficial. It must be given boldly, but cautiously, until ptyalism is produced; when the gums are touched they must be kept so for some weeks.

He has seen a case of syphilitic epilepsy which had resisted the most heroic doses of iodide disappear like magic before a mild ptyalism. He usually employs blue mass guarded by opium.

Damiana as an Aphrodisiac.

Dr. Byrd, Baltimore (*Philadelphia Med. Times*), advocates the use of damiana as an aphrodisiac. He claims for it that in this respect it is as powerful and reliable as quinine when used as an anti-periodic. He uses the fluid extract preparation as the best and most reliable.

Carbolic Acid as a Local Anæsthetic where the Actual Cautery is Applied.

Dr. Levis, Surgeon to the Pennsylvania Hospital (*Philadelphia Med. Times*), recommends the use of pure carbolic acid for the prevention of pain after the application of the actual cautery. The carbolic acid, liquefied by heat, must be painted upon and for a short distance around each point where the cautery has been applied. The parts should then be covered with some light dressing.

NOTICES TO CORRESPONDENTS.

*** An accident at the steam machine, for which our Printer is responsible, has caused the delay of a few hours in publication.

☞ Correspondents requiring a reply in this column are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule

Reading Cases.—Cloth board cases, gilt-lettered, containing 26 strings for holding each volume of the Medical Press and Circular, can now be had at either office of this Journal, price 2s. 6d. The postal regulations not allowing the Journal to be stitched, these cases will be found very useful to keep each weekly number intact, clean, and flat, after it has passed through the post.

Candidates for the Indian Medical Service are notified that examinations will be held on August 14th. Names must be sent in to the India Office, Whitehall, in July.

Army Medical Candidates will be examined in London on 14th August. Applicants must address the Director-General of the Army Medical Department a fortnight before the date of examination.

Mr. J. B. R.—The appointment is not now in the hands of the Lord Chamberlain.

Dr. Meldon.—We had imagined there were institutions of the kind in France, but having made careful inquiries we are unable to give you the address of any. If, however, it is a matter of much importance to you, we will institute inquiries in other directions.

Mr. Stott.—Received with thanks.

T. E. G.—Not suitable for our columns.

Dr. J. P. A.—We have written to our agents on the subject.

Osteotomy of the Femur.—The patients who were exhibited at the meeting of the Clinical Society on May 12th, and at the Harveian on the 18th, to illustrate Mr. Maunder's paper on Osteotomy, had been individually submitted to section of the femur by means of *three* chisels, as suggested by Volckmann, of Halle. On the former occasion Mr. Maunder showed a chisel (a carver's, three-eighths of an inch wide) which he expected would supplant the use of the three of a different pattern. His expectation has been fulfilled in the case of a male adult submitted to this operation on May 17th. The bone was readily divided, and no method could be more simple nor occupy less time. The straightforward action of a chisel would seem to be less likely to damage structures than the repeated to and fro movement of a saw. There would also be less *débris* than would be produced by the saw.

Communications, Enclosures, &c., have been received from—Sir Henry Thompson, London. Mr. Barnard Holt, London. Professor Humphrey, Cambridge. Mr. Tatham, Leeds. Professor Crookes, London. Dr. Alexander Harvey, Aberdeen. Mr G. M. Dickinson, Paliton, Rugby. Dr. Dolan, Halifax. Dr. Handsel Griffiths, Dublin. Dr. Balthazar Foster, Birmingham. Dr. W. H Barlow, Manchester. Mr. Thos. APPOINTMENTS.

Collins, H., M.R.C.P.Ed., M.R.C.S.E., Medical Officer for No. 3 District of the Dursley Union, Gloucester hire.

Cox, W. A., M.B. Univ. Ed., L.R.C.P.L., Medical Officer for the Aylestone District of the Blaby Union, Leicestershire.

Dutt, B. L., M.B., C.M., Assistant Medical Officer to the Somerset County Lunatic Asylum, Wells.

Fleming, J., M.D.Q.U.I., L.R.C.P.Ed., Medical Officer, &c., for the Ballarena Dispensary District of the Limavady Union.

Fleming, W. J., M.B., Lecturer on Physiology in the Glasgow Royal Infirmary School of Medicine.

Gibbs, B., L.R.C.S.Ed., L.R.C.P.I., Medical Officer, &c., for the Coolock and Drumcondra District of the North Dublin Union.

Hetley, H., M.B. Univ. L., M.R.C.S.E., House-Surgeon and Apothecary to the Leicester Infirmary and Fever House.

Hopkins, H. C., L.R.C.P.Ed., M.R.C.S.E., Pathological Registrar to the Royal United Hospital, Bath.

Jacobson, W. H. A., M.B. Oxon., M.R.C.S.E., fourth (additional) Assistant-Surgeon to Guy's Hospital.

Llewelyn, T., M.D., Honorary Physician to the Royal Academy of Music of London.

Maclaren, J., L.R.C.S.Ed., Medical Superintendent of the Stirling District Asylum.

Moody, J. M., M.R.C.S.E., Junior Assistant Medical Officer to the Brookwood Lunatic Asylum.

Myrtle, A. S., M.D., President of the Leeds and West Riding Medico-Chirurgical Society for the ensuing year

Spicer, R. H. S., M.D. St. And., L.R.C.P.Ed., Medical Officer for No. 3 District of the South Molton Union.

Wales, J. A., L.S.A.L., Medical Officer for No. 4 District of the Pontefract Union.

Wise, A. T. T., M.R.C.S.E., House-Surgeon to St. Mary's Hospital, London.

Marriage.

Edwards—Baynes.—On the 18th inst., at the Cathedral, St. John's, Antigua, W.I., Arthur Elliott Edwards, M.R.C.S. Eng., to Sarah, eldest daughter of Edwin Donald Baynes, colonial secretary and Lieutenant Governor of the Leeward Islands.

Deaths.

Clarke.—On the 7th May, at Poulton-le-Fylde, Thomas Clarke, M.R.C.S. Eng., aged 37.

Davidson.—On the 12th May, at Gloucester crescent, John Davidson, M.D., aged 75.

Dennis.—On the 3rd May, at Buckingham Palace Road, London, Wm. Dennis, M.D., aged 70.

Hall.—On the 7th May, at Birch Lane, Longsight, Manchester, Robert Hall, L.R.C.S. Edin., aged 66.

Hutchinson.—On the 7th May, at Bromley, Kent, John Hutchinson, M.R.C.S. Eng., aged 66.

Mallory.—On the 12th May, at Stanhope, Durham, Henry Leigh Mallory, L.R.C.P. Edin., aged 35.

Marris.—On the 17th May, at Kingsland, Herefordshire, Robert Pettener Marris, M.R.C.S., in his 75th year.

Milner.—On the 9th May, at Lower Belgrave Street, Wm. Milner, M.R.C.S. Eng., aged 57.

Morris.—On the 4th May, at Plaistow, Essex, Ellis Jones Morris, L.F.P.S. Glasg., aged 54.

Todd.—On the 9th May, at Dysart, Robert Todd, M.D., aged 58.

Unwin.—On the 15th May, at Fernlea, Surbiton Hill, John Raggett Unwin, F.R.C.S. Eng., aged 65.

Whitton.—On the 5th May, at Wolverton Manor, Corbett Whitton, M.D., aged 56.

THE GENERAL COUNCIL OF MEDICAL EDUCATION AND REGISTRATION.

TUESDAY, MAY 30.

WE concluded in our last with the proceedings of the Council to the end of the debate on the Government Vivisection Bill on Monday, when the Report as amended in Committee of the whole Council was ordered to be entered on the minutes: On Tuesday

LORD CARNARVON'S BILL ON VIVISECTION

again occupied a considerable portion of the Council's time on the discussion of a rider by Mr. Simon, which that gentleman proposed should be embodied in the Report the Council had decided to submit to her Majesty's Government. The rider ran as follows:—"In conclusion, the General Medical Council would submit to her Majesty's Government that in suggesting the above amendments in Lord Carnarvon's Bill, the Council have no desire to provide legal immunity for persons (if such there are in this country) who, under pretext of scientific purpose, would be willing to act cruelly towards any brute animal. But the Council are satisfied, and they refer to the Report of the Royal Commission in support of this assurance, that in this country there does not exist, nor, in the present state of public and professional opinion, is likely to exist, any appreciable class of such persons. And the Council would regret that her Majesty's Government, in order to provide safeguards against a greatly exaggerated danger, should proceed as if a willingness for cruel action were general among persons engaged in studying and teaching the physiological and medical sciences, and should submit those studies to such minuteness and stringency of regulation, as if they were of criminal intention."

Mr. Simon in furtherance of the object he had in view with this idea, said there was a general feeling in the committee that persons engaged in scientific pursuits had very great ground of complaint against the spirit in which Lord Carnarvon's Bill had been conceived. All, or nearly all, the amendments which the Council had adopted referred to the tendency to impose extremely minute and stringent regulations on persons who, in the course of their scientific pursuits, might have to deal with animal life; this rider, he conceived would show that the Council entirely sympathised with the public in their desire that animals should not be subjected to anything that could reasonably be called cruelty, as compared with the general use which was made of brute creatures. They were willing to accept any reasonable amount of regulation, but they demurred to regulations conceived in a spirit of universal suspicion against the profession.

Sir W. Gull as seconder, remarked that the public mind was in an exaggerated frame in respect to these matters, and he felt that one might have as well appealed to the sixteenth century against witches as in favour of careful legislation at the present time on the subject of vivisection. Lord Shaftesbury had said that if he could he would even carry legislation so far as to prevent any form of vivisection whatever, if it were in his power. He however, felt that the common sense of the country would be against him, thus extreme, when the real question was whether there was to be an extinction of biological knowledge in this country.

Sir D. Corrigan with a view to make the rider still stronger, proposed to add to the last sentence the words "And, in fine, the General Medical Council submit, on mature consideration, that the whole subject is not one for legislation at present, but may be safely left to the control of public opinion and humane feeling." He would not bind himself to say it might never be necessary to have legislation on the subject, because human nature might become much more cruel and unreasonable than it was now, but he thought the Medical Council ought to put on record an expression of their opinion that at present they considered the question was not one for legislation. From the general expression of feeling at the Board, he was sure not one member of the Council would say that legislation was necessary.

Dr. A. Smith seconded the amendment, as it was in entire accordance with the opinions he had formed in the early stage of the debate.

Dr. Rolleston said the committee had bestowed great

pains on the consideration of this report, sitting six hours a day for two successive days, and he thought the Council would do well not to accept Mr. Simon's rider. Although opposed to the opinions of many members of the Council in this matter, he nevertheless thought the restrictions which it was proposed to place on the practice of vivisection marked a step onward and upward in the progress of the race.

After a few words from Dr. Quain, Mr. Simon's proposition was agreed to with only two dissentients.

Sir D. Corrigan then submitted his amendment as an addition, which was however negatived.

In further consideration of the report a few verbal alterations were suggested.

Mr. Simon proposed "That the rider just adopted be referred, together with the previously adopted sections of the report, to the committee on Lord Carnarvon's Bill, and be brought up to-morrow," which was agreed to.

Prof Lister suggested that the word "severe" should be introduced before the word "pain" in Clause 2, page 1, of the Bill, lines 12, 14, and 23.

To this Dr. A. Wood and Sir W. Gull objected.

Sir D. Corrigan thought the report should be referred back to the committee for further consideration.

Mr. Macnamara objected to Sir D. Corrigan's proposal. If the committee had to discuss whether the word "severe" should be inserted or not, the whole question would be again discussed, and then there would be another great loss of time.

Prof. Lister said he also wished to make an addition to the first clause of the report. The report pointed out as a difficulty that the word "animal" was not defined in the Bill, and yet it did not offer any suggestion to the Government as to what the definition should be. Even if the Bill were adopted with the amendments which the Council had agreed to, there would still be a terrible interference with the progress of biological knowledge. If that every animal that writhed and wriggled was supposed to be suffering, and everyone who made experiments with such a moving animal was to be had up for a high crime and misdemeanour, it would have a most disastrous effect on physiological investigation. As the Bill at present stood an exhibition of the circulation of the blood in a frog's web would be absolutely illegal. It was all very well to say that that could not be so because such an exhibition did not inflict pain. If the principle was adopted that the frog suffered as a man suffered, then he considered a more painful experiment could hardly be imagined than to tie, so to speak, tne finger-tips of a frog with a string. If there was no limitation with regard to the meaning of the word "animal" the Bill might operate in a most serious way, and he thought it was the duty of the Council to suggest some limitation. His suggestion that the word "warm-blooded" should be introduced before the word "animal" had been objected to, and the only other way that occurred to him of securing the object which he had in view was to use the word "severe" before "pain." There were many things that would be absolutely prohibited by the Bill as it at present stood, such as the vaccination of an animal, or the introduction of a fluid into a vein. The inocculation of a cow or any other animal with small-pox was a matter to be put down by law. It might be argued that the word "severe" was indefinite, but so was the word "animal." The definition must be left to the common sense of juries, and he believed the introduction of the word "severe" would offer very good security to the profession, while at the same time it would provide for all that could be reasonably contemplated by the Act. If as a scientific body the Council was aware that the manifestation of movement under irritation was not an indication of pain, they were bound to give some sort of expression to that knowledge, and he believed that the insertion of the word "severe" would tend to mitigate the severity of the Bill.

Dr. Rolleston considered it was unnecessary to use the word "severe," as the whole question was one of expediency. It must not be supposed that magistrates and the Home Secretary would be guilty of gross absurdities in prosecuting scientific men of high position for performing slight experiments. The decision as to what was really pain must be left to the comman sense of magistrates. He, therefore, hoped the Council would accept the report of the committee without spending more time on its consideratioo.

The Council declined to sanction Prof. Lister's alteration, and the report was referred back to the committee for correctian of a few clerical errors.

REPORT OF THE COMMITTEE ON BILLS.

Dr. Thomson moved the adoption of the first section of the report, which dealt with the Bill introduced by Mr. Cowper-Temple.

Mr. Quain seconded the motion.

Sir. D. Corrigan, in proposing an alteration in one of the paragraphs, said Mr. Cowper-Temple had introduced the Bill because women were precluded from obtaining licences from the examining bodies in this country. If the Council rested their protest on the statement that the registration of foreign degrees was subversive of the Medical Act, it would be contended by the supporters of the Bill that they first established a monopoly for men, and then adduced that exclusive monopoly as an argument for not agreeing to the Bill.

Mr. Macnamara said the committee had most carefully guarded themselves against giving any decision on the question of the admissibility of women to the profession. The real reason why they were opposed to the registration of foreign degrees was that the Council had no means of exercising any supervision or control over the examinations. This prevented them from registering foreign degrees acquired by men, as a matter of fairness, therefore they could not register women who had obtained diplomas abroad.

Dr. A. Wood said there could be no doubt that the object of the Bill was to settle the woman question by a side wind, and he objected to such a proceeding. If women were to be admitted to the profession, let them be admitted fairly and honestly by a Bill brought into Parliament for the purpose, and let them be put under proper supervision, but it was not worthy of the British Legislature to admit foreign universities to qualify women for registration here while the licensing bodies at home could not grant such licences to women. He thought the Council would be false to its own position if it did not maintain intact the principle that they would not admit to registration qualifications obtained at examinations over which they had no proper supervision. The Council ought to have no difficulty in voting for the motion, whatever opinion was entertained about the admission of women.

The first section of the report which runs as follows was thereupon adopted :—

THE ADMISSION OF FOREIGN DEGREES.

"The committee on Parliamentary Bills, &c., having taken into consideration the various documents referred to them, have agreed to the following report :—

"The committee have to observe that the Bill introduced by Mr. Cowper-Temple, with the exception of a few slight verbal alterations, and the addition of Vienna to the list of foreign universities in the schedule, is precisely the same as that which was brought forward last year, and upon which the Medical Council stated its opinion to the Government. The committee see no reason for a change in the views of the Council on the questions involved in the Bill, and they therefore recommend that an answer be transmitted to the Lord President's inquiry with respect to Mr. Cowper-Temple's Bill, in the same terms as that of last year—viz., as follows :—With regard to Mr, Cowper-Temple's Bill 'to amend the Medical Act, 1858, so far as relates to the registration of women who have taken the degree of Doctor of Medicine in a foreign university, considered by itself, and apart from its bearings on the general question whether women ought to be able to look to medical practice, or certain branches of it, as open to them equally with men, as a profession and means of livelihood, the Council have found no difficulty in forming an opinion.

By the Medical Act, 1858, the Council are precluded from registering foreign degrees, and, consequently, have been compelled repeatedly to refuse to register foreign degrees held by men. The reason for this is obvious—viz., that the Council have no means of exercising that supervision and control over the education and examination required for foreign degrees to which the licensing bodies of this country, whether universities or corporations, are, by the Act of 1858, subjected. But this privilege, which the Medical Act on this account refuses (and the Council believe, very properly refuses) to men, Mr. Cowper-Temple's Bill proposes to grant only to women. Against such a proposal the Council feel bound to offer a protest, as being subversive of the main principle of the Medical Act. The committee would further remark that it is deserving of notice that the degrees of Doctor of Medicine conferred by some of the foreign universities of highest repute included in the schedule to Mr. Cowper-Temple's Bill, do not authorise their holders to practise their profession in their own country unless they shall also have passed subsequently, and in addition, a State examination."

PUBLIC APPOINTMENTS IN THE UNITED KINGDOM.

The following is the section of the report relating to Mr. Gibson's Bill :—

"With respect to the Bill introduced into Parliament by Mr. Gibson, the committee would remark that the first part of this Bill appears to have been framed to meet special restrictions existing in Ireland, and that it proposes to open up to all legally qualified registered practitioners all public medical and surgical appointments in the United Kingdom. The committee is of opinion that before such a measure is passed by the Legislature, it would be expedient to obtain full information as to the effect which the enactment of the Bill (Clause 2) would have in throwing open indiscriminately appointments in public hospitals in the United Kingdom, the qualifications for which are at present regulated by charter or otherwise.

"As regards the further provisions of the Bill (Clause 3) the committee are of opinion that power should be given to register the degree of Bachelor of Surgery from any University of the United Kingdom entitled to grant the same.

"As regards a degree or diploma or certificate in State Medicine or Public Health the committee are of opinion that it should be registered only as an additional qualification by persons whose names are already enrolled on the Medical Register under the Medical Act.

"The committee are further of opinion that the privilege of such registration should not be confined to universities, as provided in the Bill, but should also be extended to all diplomas in State Medicine or Public Health granted by any of those bodies included in Schedule (A) of the Medical Act, which may institute the necessary examination."

Dr. Thomson moved the adoption of the first clause. By Clause 2 of the Bill, he said, it was proposed that all public appointments in hospitals should be thrown open to every registered practitioner. It was somewhat doubtful as to what would be the effect of such a Bill, whether it would merely render all registered practitioners eligible, or impose upon the different bodies the obligation of electing candidates without reference to particular qualifications, provided their general merits entitled them to the place. If the latter were the real meaning, the committee thought it necessary that the circumstances of the public hospitals should be known before legislation was undertaken, though there was a general feeling in favour of the removal of impediments to duly registered practitioners accepting appointments.

Prof. Turner said the Bill had been introduced in order to remedy an injustice in Ireland, where no one was capable of being elected a surgeon to a county infirmary or hospital unless he had letters-testimonial from the Royal College of Surgeons, but many of the clauses seemed to give the measure a much wider scope. Instead of being merely an Irish Bill, as the preamble would lead one to anticipate, it really applied to all the three divisions of the kingdom. That being the case, it seemed to him that the Legislature had not got sufficiently full information on the subject.

Mr. Macnamara said he did not by any means admit that any grievance existed from the infirmaries of Ireland being supplied with practitioners qualified by the College of Surgeons of Ireland; but the College did not wish to persevere in any monopoly. They were perfectly willing to have the fullest and freest competition for public appointments. The licentiates of the College of Surgeons of England or Scotland could go over and compete with Irish licentiates if they liked; but there should be reciprocity, and the Irish practitioners should also be allowed to compete for appointments in English and Scotch infirmaries. The College of Surgeons in London and the College of Surgeons in Edinburgh had similar monopolies to that possessed by the College of Surgeons in Ireland, and he was quite willing to have the monopoly in Ireland abolished, provided those in England and Scotland were on the same footing.

Clause 2 then passed.

QUALIFICATIONS IN STATE MEDICINE.

Dr. Thomson in moving the adoption of the third clause remarked that many members of the Council were aware of the great care and attention which the Council had devoted to the whole subject of State Medicine qualification. Since that time the subject had made some progress in the minds of public men, and the general feeling now was that, while it was most important and desirable to grant qualifications in State Medicine upon proper conditions, yet those qualifications should be founded upon the groundwork of a full medical education, so that no person might be qualified to offer advice to the public upon that subject unless he was also well-informed with regard to other branches of his profession.

This clause also passed.

Clause 4 and last gave rise to considerable discussion.

Mr. Simon proposed as an amendment the omission of it altogether. He felt considerable doubt as to whether it was desirable to create an entirely new and separate action for a great number of bodies.

Dr. A. Smith second the amendment.

Mr. Macnamara opposed the amendment, remarking that the Royal College of Surgeons of Ireland was the first body to institute a professorship of hygiene, and ought not now to be told that they should not give a licence in State Medicine.

The President stated that the University of Cambridge at present admitted any registered practitioner to its examination for the qualification.

The discussion on Mr. Simon's amendment had not concluded when the time for adjournment arrived.

WEDNESDAY, MAY 31ST.

The discussion on the clause, "The Committee are further of opinion that the privilege of such registration should not be confined to universities as provided in the Bill, but should also be extended to all degrees, diplomas, and certificates in state medicine or public health, which may be granted by any of the bodies included in Schedule (A) of the Medical Act, which may institute the necessary examination,"—which was left unfinished at the close of Tuesday's sitting, was resumed.

Mr. Macnamara again resumed his reasons for objecting to the proposed amendment by Mr. Simon, and said that he felt very strongly that the conferring of degrees and diplomas in state medicine should not be confined to the universities. Sanitary offices were becoming very important in Ireland, and it would be a great hardship for Irish candidates not to be able to obtain the public health qualification without obtaining the degree of arts required by the University of Dublin. To require them to go to

Cambridge, which was open to all, would be inflicting a fine of £8 or £10 on each. He could not see why there should be the slightest objection to accede to the proposal of the Council. Ample provision for the efficiency of the qualifications would be provided by proper supervision; if the regulations were unsatisfactory the Council would reject them. The Royal College of Surgeons in Ireland had a professorship of hygiene since 1844. It was hard that that College, or any other of the licensing bodies should be excluded from giving certificates in state medicine; he believed that such exclusion would be one of the greatest checks to the progress of hygiene that could be inflicted. He would point out to Dr. Smith that, if the privilege were extended to the College of Physicians in Ireland, it did not follow that it should at once institute an examination in public medicine, but the possession of the privilege might be of importance to the College afterwards.

Dr. Pitman believed that the matter had not been looked at in its various aspects. The words degree and diploma conferred certain privileges; but the Committee had resolved that the diploma in state medicine should be registered as a title. If so there was no place for it in the Medical Act. If it were admitted, the door would be open to the dental licentiates of the Royal College of Surgeons, Fellows of the Obstetrical Society, &c., to claim registration. With regard to certificates, anybody could give one. The clause in the Bill referred to degrees legally granted by Universities. He thought that the Council would introduce confusion if advised that the diplomas in state medicine granted by all the bodies should be registered.

Prof. Turner said that it was evident that many of the licensing bodies had taken steps to institute diplomas in state medicine. Was it for the Council to recommend that such qualification should be put on the Register? The objection might be made that this would introduce a number of new qualifications, the examinations for which the Council would be called upon to supervise. It was, however, a question of justice to those bodies which had instituted examinations in state medicine, and these should be considered.

After further discussion mainly in favour of the recommendations of the committee, in which Dr. Rolleston, Dr. Wood, Sir Dominic Corrigan, Dr. Quain, and Dr. Smith took part, Mr. Simon withdrew his amendment, his opinions having undergone a change, as he remarked from the weight of Mr. Macnamara's arguments, and the clause as originally proposed passed.

The Council next discussed the measure about to be introduced into the House of Commons by Mr. Russell Gurney, entitled—

A BILL TO REMOVE RESTRICTIONS ON THE GRANTING OF QUALIFICATIONS FOR REGISTRATION UNDER THE MEDICAL ACT ON THE GROUND OF SEX.

Be it enacted by the Queen's most Excellent Majesty, by and with the advice and consent of the Lords Spiritual and Temporal, and Commons, in the present Parliament assembled, and by the authority of the same:

1. The powers of every body entitled under the Medical Act to grant qualifications for registration shall extend to the granting of any qualification for registration granted by such body to all persons without distinction of sex.

2. This Act shall be taken to be incorporated with the Medical Act, as amended by the Act of the twenty-second year of Her Majesty, chapter twenty-one, and the Medical Act as so amended, and any other Act amending the Medical Act shall be construed, and have effect accordingly.

On this the following action of the Council was taken, one or two resolutions and amendments were negatived:—"That the Third Section of the Report of the Committee on Parliamentary Bills be remitted to the Committee, with power to consult Mr. Ouvry as to the legal bearings of the first clause of Mr. Russell Gurney's Bill, and also generally upon the whole question."

The committee on Parliamentary Bills was also increased by the addition of Dr. Storrar, Professors Turner and Lister, and the Council's solicitor was requested to attend the following day in accordance with the foregoing resolution.

The fourth and fifth sections of the Report were remitted to the committee on Parliamentary Bills, and the sixth section which treats of—

FOREIGN DEGREES

was agreed to.

"With respect to the communications from graduates holding foreign degrees, suggesting that these degrees should be admitted to the *Medical Register*, the Committee recommend that in acknowledging these communications the Council should express their opinion that no qualifications should be entered in the *Register*, over the education and examinations for which the Council cannnot exercise the same supervision and control as they do under Section xviii. and xx. of the Medical Act, in regard to the qualifications granted by the British licensing bodies, mentioned in schedule [A] to that Act."

CERTIFICATES IN LUNACY.

The President made the following communication with respect to certificates in lunacy, to which reference was drawn in our last.

"The correspondence is similar in purport to that printed in vol. vi of the minutes. Mr. Forbes, Secretary to the General Board of Lunacy in Scotland, writes (29th July 1867) that Mr. Secretary Hardy had laid a case before the law officers of the Crown, and they are of opinion that upon the true construction of the statutes, certificates signed by medical men in Scotland do not constitute a valid authority for the detention of Lunatic patients in England and Wales, and *vice versâ*. In July 1868, the President of the Medical Council (Sir George Burrows) drew the attention of the Home Secretary to the subject, and on August 10th, 1868, Mr. Liddell replied that Mr. Secretary Hardy having consulted the Lunacy commission was unable to undertake further legislation for the purpose of removing the anomaly. In 1869 there was a correspondence between the President of the Medical Council (Dr. Paget) and the lunacy boards of Scotland and Ireland, and about the same time the matter was laid before the Lord President (the Marquis of Ripon). The affair seems not to have been pursued further. Under all these circumstances, it appeared to be desirable to see the chairman of the Lunacy Commissioners on the real merits of the case. He (the Earl of Shaftesbury) having carefully considered the subject, stated that he did not think the matter to be in exactly the same position as it had been when it was previously discussed; that there would probably now be no objection to consider it in connection with other subjects proper for a Bill having relation to the Lunacy Acts; that it should, after conference with the other Lunacy Commissioners, be so considered, and he hoped that it might be possible that an evil, the existence of which he fully felt, might be remedied next Session, if a Lunacy Act could then be brought in. I further promised his Lordship a copy of all the papers we have on the question; and, subject to your wishes, I purpose, in conjunction with Mr. Ouvry, also to prepare a copy of the Act for transmission to the Secretary of State for the Home Department."

The remainder of the sitting was occupied in discussing the duties and emoluments of the Registrar, the amended report of which will be found in Thursday's proceedings.

THURSDAY, JUNE 1.

After confirmation of the minutes of the preceding day, the Council were engaged in

THE ELECTION OF A MEDICAL REGISTRAR.

The duties and emoluments of the office are as follows:

I. The Registrar of the General Medical Council shall keep his registers correct, in accordance with the provisions of the Medical Act, and the standing orders of the General Council.

II. The Registrar shall verify each page of his registers with his signature, and every alteration, addition, or erasure shall be verified with his initials.

III. The Registrar shall fulfil all the duties now required, or which may hereafter be required of him, by the standing orders of the General Council.

IV. The Registrar shall be present at every meeting of the General Council, and of the Branch Council for England, and at other meetings when his presence is required, and shall take minutes of the proceedings at such meetings.

V. The Registrar, as Secretary, shall conduct and have charge of the correspondence on the part of the General Council, and of the Branch Council for England, and shall issue all requisite notices.

VI. That the Registrar do not retain in his hands more than £100 of the funds of the Council, but shall lodge all moneys as they accumulate in the Bank of England, to the credit of "The Branch Council of Medical Education ond Registration of England."

VII. The Registrar shall, in addition to one of tha Treasurers, sign all cheques on behalf of the General Council or Branch Council for England.

VIII. The Registrar shall have the general control of the management of the office, authority over the clerks and servants, and superintendence of the building.

IX. The Registrar shall attend at the office from twelve to four o'clock daily, and at other times when necessary.

X. The Registrar shall not be absent from his duties unless by permission of the President or the Treasurers.

XI. That the salary of the Registrar shall be £500 per annum.

Dr. Andrew Wood said his object in delegating this appointment to the executive committee was chiefly on the score of expense. Dr. Hawkins intended resigning in November, and if the whole Council were summoned it would cause the expenditure of nearly £300, which would be thus saved.

The Council accepted Dr. Wood's suggestion, and the vacancy will be advertised in the medical journals in due course.

THE FINANCE REPORT OF THE COUNCIL.

Dr. Quain, as chairman of this committee, then moved the adoption of the report.

The finance committee report that the income of the Council during the year 1875 has been £5,877 19s. 8d.—a sum less by £126 6s. 6d. than the income of the preceding year. The expenditure of the Council during the same period has been £6,698 19s. 6d. The expenditure of theyear has therefore exceeded the income by £820 19s. 10d.

The principal items under which an increase of expenditure has taken place, as compared with that of the preceding year, are on visitations of examinations, £261 9s. 0d. ; on printing £405 1s. 6d. ; on house expenses £114 3s. 7d.

A table has been drawn up, showing the receipts and expenditure of the Council during the last six years. From this table we learn that during the first four of these years the income exceeded the expenditure by an average amount of £1,073, whilst it will be seen that during the past two years 1874 and 1875 the expenditure exceeded the income by the amounts in each year respectively of £877 and £817, the income during these years being rather above than below the average.

It will be observed that during the first of these two years —viz., 1874, a great portion of the excess of expenditure is due to the outlay for reprinting the "Pharmacopœia," which cost £688 18s. 6d., and for which the Council has been already reimbursed. The remainder of the excess is to be accounted for by an increased outlay for general printing and house expenses.

The excess of expenditure of the last year, 1875, is to be accounted for by the amount of fees paid to visitors of examinations, which exceed the amount paid in the preceding year by the sum of £261 7s. 2d ; by the cost of general printing, which exceeds that of the previous year by the sum of £405 1s. 6d. ; and lastly, by expenses connected with the office and house, which exceed that of the preceding year by £111 3. 3d.

The committee feel that the Council will agree with them in thinking that the expenditure of the Council should not be allowed to continue in excess of its income. To some extent this evil will be remedied, should the Council determine to extend the visitation of examinations over a series of years, by which the annual cost will be diminished. No very material reduction can be made in hoe usexpenses. The other item of increased expenditure is that for printing ; and as during the last year one-half of the whole excess of expenditure—(viz., £405 1s. 6d., out of £802 0s. 1d.), is due to this alone, the committee would recommend that for the future a stricter economy should be exercised in this department of the expenditure.

A discussion arose on the increase of expenditure during the past year, which was explained by the expenses attending the visitations of examinations which had been recently initiated and carried to such a useful issue. These examinations would not in future be held all in one year, so that the attendant expenses would be spread over several years. The house expenses had also increased of necessity on account of the removal to the new and more commodious premises now occupied by the Council. The only item the committee saw it possible to reduce was the printing account, which they suggested should be subjected to more rigid economy. The report was then adopted.

LORD CARNARVON'S VIVISECTION BILL.

The amended report of the vivisection committee was then brought up by the chairman, Professor Lister, and after an animated discussion, the Council decided to remit a copy of the said report to every member of her Majesty's Government, the House of Lords and the House of Commons, as expressing the opinions of the Council. Having given this report minus only a few verbal alteration in our last, it is unnecessary to repeat it. Our readers will find it at page 443.

The Council were next engaged in discussing a motion of Sir Wm. Gull's on

THE CONJOINT SCHEME,

which ran thus :—

"This Council express their regret that up to this time and after so long delay no Scheme for a Conjoint Examining Board for England, Scotland, or Ireland, has yet been framed. The Council further desire urgently to press this matter of a Conjoint Board upon the Bodies whose duty it is to arrange and supervise the Medical Examinations in the several divisions of the Kingdom."

Sir Wm. Gull, before putting this to the vote, asked permission to make the following alteration : that the words "has yet been framed" should read "has yet been put into operation." This alteration agreed to, the mover said the object of his motion was obvious. Some time since the Council had decided that a Conjoint Scheme was desirable, yet several years had passed, without any practical result being achieved, or the recommendations of that Council carried into effect. He had an ardent desire for the united action of the three kingdoms ; but if this could not be obtained he would be satisfied as a first instalment with a conjoint scheme for the Universities and Corporations of England alone. There were many advantages to be derived from the one portal system, the standard of medical education would be raised, and students who had passed the minimum examination which should be alike in every case, would be placed on the Register on a footing of equality. The standard of this minimum examination might be left to the united decision of all the Corporate bodies, under the supervision of the Universities. There would then be but one examining board, and one standard of examination, instead of the present system, which had no unity of purpose or of examination, each qualifying board having a standard of its own, and each one empowered to grant diplomas, and to send forth men supposed to be qualified, with a totally different examination and an unequal standard.

Professor Turner, on the contrary, objected to the one portal system. In Scotland, for instance, it would inflict a great hardship upon the various qualifying boards. It was an every day occurrence for practitioners and students to come from the

colonies and other distant parts, and to enrol themselves as members of one or other of the universities, in the hope and expectation that if all went on well with them they would eventually become graduates, and obtain such degrees as the institution they had chosen was able to grant. He deemed it most imprudent, nay, even cruel, to compel these men and students generally who had already completed a portion of their curriculum, to submit to the double ties and expenses this conjoint scheme would entail.

Dr. Quain protested against the retrograde action of the council; five years since they had decided that a conjoint scheme was desirable, and now they were discussing the whole thing again, as if they had slept for a number of years, and woke forgetful of the past.

Mr. Macnamara did not feel that any apology was due from him in addressing them on the question of a conjoint board for each division of the kingdom, having spent many and many an hour trying to carry out some such scheme for Ireland; he expected, however, to have to inform the council that, as he understood the meaning of a conjoint scheme, such was impracticable in Ireland. Sir Wm. Gull seemed to think that examinations conducted by the corporations, in which the universities were to assist only by their presence, would constitute a system of conjoint examinations. This might do for England where this class of students were licensed by the corporations, comparatively few being qualified by the universities, but such scheme carried out in Scotland and Ireland, where a large proportion of the students are qualified by the universities, would be a very incomplete conjoint scheme indeed. In these counties, conjoint boards, *minus* the universities, would be very much like the play of Hamlet, the part of Hamlet being omitted. In Ireland the conjoint scheme had fallen through in consequence of the withdrawal of the proposed scheme of the Queen's University. This body, though called a university, was in active competition with the corporations, inasmuch as it gives its qualifications, its M.D.'s, and its M.Ch. to students, not graduates of arts, for the bulk sum of twelve guineas. Were the degree in Arts required of its candidates, the competition would not be so severe, but such is not the case, though the facts being as he stated. Looking at all the difficulties of the case, Mr. Macnamara felt convinced that the true solution of this most difficult problem would be found in the Medical Council seeking to have an Act of Parliament passed, empowering them to refuse to register any person who had not a degree in medicine and in surgery. This Act could be passed in this very session, and coupled with a judiciously conducted system of visitation on the part of the Medical Council, every security would be afforded the public as to the education and qualifications of their medical attendants.

Mr. Teale said that the arguments by the representative of Ireland and Scotland, instead of convincing him of the impracticability of a conjoint scheme, rather confirmed him in his view as to its necessity. Certain difficulties in Scotland had been pointed out against the scheme, and in Ireland they split upon the rock of monetary competition, but these, in his opinion, would be overcome by the practical and judicious action of a conjoint board.

Dr. Wood entered into an explanation of his opinions, which he contended were at one with all the universities and corporations in Scotland as to the feasibility of the scheme in that country. Since the passing of the resolution, advising a conjoint scheme, they had loyally endeavoured to carry out the wishes of the Council, but they were met by such insuperable difficulties on all sides, as to compel him to alter his views altogether, and to confess that at least for Scotland, a conjoint scheme was utterly impossible. He had no objection to a short Bill, which should compel every student to pass a recognised examination in both medicine and surgery as suggested by Mr. Macnamara, before his name was placed on the register; but the one portal system meant unnecessary vexation and hardship to the student, and absolute failure to the corporate bodies.

Dr. Pitman said he had taken considerable interest in the question of a conjoint board, both in accordance with his official position as Registrar of the College of Physicians of London, which body highly approved of the scheme, and also because it was his personal opinion that such a consummation was highly desirable. The College of Physicians had strived to promote the success of the movement at considerable labour and expense, and he saw no reason why such should not be carried out. He would feel ashamed to take part in a resolution which had for its object the defeat of such a measure, and he hoped that whatever might be the result of Sir Wm. Gull's motion, a single examining board for each division of the United Kingdom would become *un fait accompli* at no distant period.

Dr. Haldane said that the great majority of students in Scotland passed both examinations in medicine and surgery, scarcely any went for the single qualification; he might say that so far as the Edinburgh College of Physicians was concerned, no candidate had been admitted since 1874 who had not already passed at some other Board. He was decidedly against the conjoint scheme, preferring the combination of corporations, which they found worked so well in Scotland at the present time to the one portal system, which looked very well on paper, but in its practical results would be found extremely objectionable.

Dr. Smith remarked that the motion which stood in his name, "That the contemplated conjoint scheme for England, shall be submitted to the General Medical Council for its consideration and approbation before its scheme shall be brought into operation," was most unfairly anticipated by the alterations Sir Wm. Gull had made in his own motion since it was on paper. He thought it would have been more honest if Sir William had allowed both to stand or fall by their merits, instead of endeavouring to defeat the one he objected to by a sidewind. He was strongly against the conjoint scheme, and expressed his firm conviction that so far as Ireland was concerned, it could never be carried out.

Dr. Thomson confirmed Dr. Woods' views on the subject as far as Scotland was concerned; it had been tried and found wanting. Six o'clock having arrived, the debate was adjourned.

FRIDAY, JUNE 2ND.

THE CONJOINT SCHEME *(continued)*.

Prof. Lister.—I would not object to conjunction, could it be done without inconvenience. We have at present three spurious examinations—the College of Surgeons examining in medicine, and the College of Physicians in surgery, &c. It would be better for each to examine separately, but to unite their qualifications. We are agreed it would be well to have conjunction, and I should be glad to support Sir W. Gull's motion, but the conjoint scheme has been actually prevented by striving after the one portal system. There would be no special virtue in the one portal system provided that in every portal there were strong portæ. All must regret to observe that men who rise to eminence give up their position as teachers, and in the same way as examiners. If such is the case now, it would be more surely so with the one portal system. An examinership has been hitherto looked upon as an honour, but if elected for this heterogenous body, the examiners would not be improved in quality. Examining is troublesome, and excessively unpleasant. I would not engage in it if I were not called upon to do so as a professor. Again, there was another point. If a graduate of London, why should I be called upon to pass the one portal examination—why called upon to pay the extra sum, £5 5s.? Besides, a surgeon would not require the diploma of the College of Physicians and Apothecaries; why should he therefore, be called upon to pass the examination? Again, with regard to education why should the pupil cram up the compositions of drugs, &c. Pupils should have their reflecting faculties improved, not their cramming powers. Another disadvantage: It is called a minimum examination, but it does not follow that every one would pass. I might say that a man is as likely to be rejected in this as in a higher examination for in the latter there is more care—more time. How can a man be tested in ten minutes. It may be so in a first-rate man—even three minutes may be sufficient—but a slow man, who had all the requisite knowledge, could not be examined and accurately tested in the time. The result of the conjoint scheme would be to prevent many from taking the Scotch degrees. Those who would be content with the conjoint examination would be content with much less work, and far less testing examination than the Scotch degrees. Again, with regard to teachers examining their own students, we hear of men reading up before examining,

Ought such to be. A teacher knows his students; I had a man whom I knew to be well up become so nervous that he could not tell what a case of talipes was; I should have rejected him, but knew him, gave him time, and he passed a very good examination. Again a man knows his teachers and his examiners, but if he knows that another professor may examine him, he knows not what to read, and becomes confused. If a teacher examines, the student may read the works written by those teachers, and prepares the subject well and passes a good examination. This preparation is a very serious matter. Take chemistry for instance; how harassing on such a subject to feel one may be examined by one who teaches quite differently. No one can know the whole subject of chemistry. Doubtless there is an evil in the Scotch form of examination, but the question is which is greater, the evil or the good? The evil is overcome by assessors, and this Council has enabled the Scottish Universities to improve in this respect, for they have now an extra professorial examiner, perfectly independent in every subject, and no one may examine in more than two subjects. Besides these they have visitors of examinations from the Council. For my part I am not disposed to agree with the desponding tones of Dr. Pitman and Dr. Quain, I believe the examinations are being quietly improved without any radical changes whatever. It is easy to make radical changes, but one cannot foresee the result. I cannot vote in favour of Sir Wm. Gull's motion.

Sir D. Corrigan.—I fear we have travelled off the direct line. Instead of confining ourselves in proper limits we have diverged into *not* one conjoint examination, but into three or four.

Sir Wm. Gull's resolution is this:—The Council express their regret that up to this time, and after so long delay, no scheme for a conjoint examining Board for England, Scotland or Ireland has yet been put in operation. This resolution is to express regret, and it is cleverly put, to make it appear that we all approve of a conjoint scheme. Now, sir, this is an attempt to gull the Council. We do *not* approve of the project of a conjoint scheme. Now, how many conjoint schemes have been before us? At least three. I opposed the conjoint scheme for England, Ireland, and Scotland, because if a man passed in one he passed in all three, and he could go up at one examination and if rejected then at another, and so on. Professor Turners' conjoint scheme is to put the Universities out in the cold; let them pick up any scraps, like the dogs at the table of Dives. Dr. Wood has suggested an Utopian examination. Some years ago the Council was in favour of a conjoint scheme, but many of us have changed our minds. A change has come over the spirit of our dreams. If we look back five years ago, out of eighteen voting 17 voted for a conjoint scheme, and the only one voting against it was myself. I was alone in my opinion; but I am glad to find so many of my friends come round on the present occasion to the same opinion as myself. Some years ago I was desirous of obtaining a State examination for any one who had charge of our soldiers, sailors, &c. I was supported by Dr. Smith, but it failed. Dr. Quain then said give me ten minutes and I will go to the College of Physicians. That distinguished body is now in labour on a conjoint scheme. In a few minutes I will bring you back the baby. That labour was more than a day and a night, but no baby appeared. All these schemes are futile and I shall certainly vote against the motion.

Dr. Humphry. I rise to propose an amendment, for I see that the vote of this Council will appear to be condemnatory of a conjoint scheme. Such will be the case if a division takes place on Sir Wm. Gull's motion, but such is not the desire of the Council. It is certain we shall get no such scheme in Scotland or Ireland, whilst in England the scheme is being slowly worked through. It would be very injudicious to vote and so to give an opinion apparently against the English tendency to form a scheme, whilst at the same time we are actually in favour of the conjoint scheme in England. This amendment is perfectly open, not limiting, whilst at the same time, it urges upon the examining bodies not to remain idle in the matter. I would propose a resolution to the effect that this Council desire to urge upon the several licensing bodies of schedule A of the Medical Act, the importance of union or co-operation in their examinations, so as to secure that every person admitted to the Register has been tested in medicine and surgery and other subjects deemed essential by the Council.

Dr. Fleming.—It is unnecessary that the Universities should be incorporated in the scheme. The Universities are really not the licensing bodies. The names in Register from the universities of England amount perhaps to not more than 100. Now one reason given for the formation of the Conjoint Board is that the separate examining bodies are anxious to get money, and therefore lower their scale of examination; but with regard to Scotland, this is perfectly ridiculous. We have no such idea, for our examining bodies are not in want of money. The Corporations might co-operate if they desire. In fact, in Scotland it amounts nearly to co-operation at the present time. I neither like the motion nor the amendment. This discussion, however, will go to the public and the profession, and perhaps may do much good when brought on for consideration by the Corporations. I beg leave to move the previous question.

Dr. Rolleston.—Dr. Humphry's amendment differs in no respect from Sir Wm. Gull's motion, for it urges a co-operation. Dr. Humphry adopts the words of the motion without the name of a conjoint scheme. We desire to secure, not only an examination on certain subjects, but we desire to do away with the necessity of a special State examination. If we do not do this for ourselves, it will surely be done for us. We must have an equal examination in all. We must have co-operation, that is the co-operation of all the bodies, and not one under-working the other; and if we do not you may depend that the State will see for the people that the examinations are sufficient in all the Corporations and will institute an even examination that is a State examination for us.

Dr. Andrew Wood.—Doubtless we all wish to see an equal examination, but we want to do it in the right way. Dr. Rolleston and his party think one way right and we think another way right. But we are not to be frightened to a form which we consider would not be the right way. I do not believe the State will take the matter out of our hands when they see we are working steadily, and one may add successfully towards a good end. These three Colleges in England have brought forth a phantom scheme and cannot work it. Let them acknowledge it and arrange among themselves that the examinations are fully carried out. But it may be left to them. I believe it would be unwise to bring this motion of Sir Wm. Gull's to the vote, for it would most assuredly show that the Council is of a different opinion to what it was on the last division upon the subject.

Dr. Aquilla Smith. It will go before the public and the profession that there is a change of opinion in the Council, but it would be an extremely cowardly act for the Council to suppress that opinion. I have, and so also others, changed opinion from time to time, and I see no reason to conceal the fact.

Dr. Simon. The amendment certainly tends to perplex the Council. It is not a fair amendment. But it might be brought up as an original motion, if Professor Humphry will give notice of it and bring it forward for discussion to-morrow. (Dr. Humphry then withdrew the amendment.) The Council has existed for eighteen years, and has never passed a resolution so thoroughly in accordance with the feeling of the profession as those resolutions referring to the subject now again brought before us. The consolidation of the Examining Bodies was indispensable, and without that consolidation it would be impossible for the Council to maintain a high standard of qualification. It has been said the Universities might be separated from the scheme. I should regret such a scheme. It is quite unimportant that they should exa-

mine, but I should indeed regret that they should not be associated in the scheme. In concurring in the motion of Sir William Gull I hope I am not unduly influenced by any other feeling than that of right. In England I have not the least doubt that we shall have a conjoint board: the public spirit and the present tendency of the Universities and Corporations all tend to such. Now what will be the result? There will be a tendency in the English opinion to estimate at a low degree the Scotch examination. It is said this Council has changed its opinion since 1872. On the contrary, I believe the opinion to be much as it was then. It was only gradually, only reluctantly, only in recognising that there was a common interest—in fact, an obligation—that the Council then voted as they did vote.

Dr. Quain: I think we don't know why the corporations have disregarded our resolutions. I think it would be right not to censure them as this resolution would do, but ask them again why those schemes are not in operation. We should then be able to come to some conclusion. I hope by that time to bring before you the completed scheme of the London College of Physicians. If we don't carry a Conjoint Board, I am convinced the Government will frame a Conjoint Board for us. No Government will permit nineteen bodies to exist with a different standard of examination. In fact, a State examination was before the House, and was actually passed in the Lords. I may add how absurd it seems. The College of Surgeons and other corporations have got an Act of Parliament, and now we are to say we have changed our minds. After all this labour of love on all sides, the Council say our opinion is not now as it was then; we should be laughed at on all sides.

Dr. Quain then proposed an amendment to refer the matter back to the corporations, but it was subsequently withdrawn.

Sir Wm. Gull: I confess I am surprised to see men coming from all parts of the world and taking sides, not deliberating, but actually taking sides. The examination may be considered a minimum, but this minimum is to raise the standard of examination. Mr. Lister refers to the position of examiners. If there were one examining body to each division of the kingdom, there would be no difficulty in having good examiners on the several subjects. As Mr. Macnamara says, there is a tendency in some bodies to get students cheaply. I have always felt that a student might pay for his honours as he pays for his education, and the fees should be raised accordingly. I am told that the visitors of examinations in some cases did not actually visit (contradicted). Whether such is the case or not, at any rate there must be a great difficulty in visiting nineteen bodies. Professor Lister speaks in favour of teachers examining their own students. This we object to altogether. Suppose you have an ignorant teacher examining an ignorant student, where are you then? An examiner is a very important member of society, and it is very difficult indeed to obtain good examiners. We cannot find good examiners for so many bodies, for they do not actually exist. England should certainly bring forward a scheme, and then I have no doubt Scotland and Ireland will follow, so I have worded the motion for England, *or* Scotland, *or* Ireland. I don't care which is first, or which has the honour of precedence.

The President: I look upon the question as a national one. If this body is doing a national service it must leave out all personal matters. On looking back I find strong expressions on the part of the Council in favour of the Conjoint Scheme. Now, I say a Conjoint Board will certainly be formed; but in what form? If a Conjoint Board is first formed it may be between the Colleges of Physicians and Surgeons; if not, the two must license in subjects foreign to the respective colleges. I should very much regret to see the Universities not in association with the Corporations, and I believe it would be a great misfortune if the Corporations should unite without including the Universities. If the Council should vote against a Conjoint Scheme they may perhaps be the means of preventing a conjunction between all the Examining Bodies, but they certainly will not prevent co-operation or conjunction in the examination. As regards England I am sure, as regards the other divisions of the the Empire I am not sure, but it is our desire and our duty to obtain a uniform and satisfactory examination throughout the Empire. Whatever may be decided by this Council, whether you divide upon the question or not, we may I am sure feel satisfied that this discussion must have an important influence in directing the action of the Examining Bodies.

The division—15 in favour of Sir William Gull's motion, 6 against.

Dr. Humphry's former amendment upon Sir W. Gull's motion was now put as an original motion.

Dr. A. Wood: I think that next year we shall have *no* more Conjoint Boards than we have at present, and therefore think it advisable to press some form of combination upon the Examining Bodies.

Dr. Macnamara could not see how this resolution could strengthen the former resolution.

Dr. Rolleston thought the resolution simply weakened the previous resolution.

Prof. Humphry: Those who voted against the former resolution were all the English and 4 Irish members. We scarcely expect a Conjoint Scheme therefore in Scotland or Ireland, and I therefore desire that this Council should urge some combination upon those bodies who are not at present likely to adopt a Conjoint Scheme.

Dr. Storrar looked upon this motion as qualifying Sir W. Gull's, and therefore would vote against it.

When put to the vote, 10 voted for and 12 against the resolution.

Dr. A. Smith: You said, Sir, a Conjoint Board would certainly be formed in England, and you added that the particular form was doubtful. Sir Wm. Gull said if a Conjoint Board for England is carried it will certainly necessitate a Conjoint Board for Scotland also. I therefore distinctly think it necessary that no scheme should be allowed to come into operation without the approbation of this Council.

Dr. Smith moved a resolution to that effect, but it was not seconded.

VISITATION OF EXAMINATIONS.

Moved by Dr. Quain; seconded by Dr. A. Smith, and agreed to:—"That the following report of the Executive Committee on the best means of conducting visitations of examinations, as amended by the Council in committee, be entered on the mintues and adopted."

REPORT.

General Regulations for the Visitation of Examinations.

1. That when the Council shall at any time decide to resume the visitation of examinations, arrangements shall be so made that the series shall be completed within a period of five years. Such arrangement not to interfere with any special invitations which the Council may think fit to direct to be made.

2. That the arrangements for the visitations, and the appointment of the visitors, and all the details thereof, not otherwise provided for by the Council, shall be entrusted to the Executive Committee.

3. That the various examining bodies shall be requested to forward, before a fixed date to be named by the Executive Committee, to the Registrar of the General Medical Council, a statement, showing the subjects of examination, as well as the days and hours at which the several examinations will be held by them during the ensuing year.

4. That the visitations shall be conducted by members of the Council jointly with others not members of the Council.

5. That the visitors shall be paid for the discharge of the duties of visitation, for their travelling expenses and maintenance, at the same rate as that fixed by the General Council, and approved by the Lords Commissioners of H.M. Treasury, for attendance at the meetings of the Council.

6. That as far as possible the visitors shall be made acquainted with previous reports of the examinations they are about to inspect, and also of the remarks of the licensing bodies on those reports.

7. That the duties of the visitors shall be to inquire into and report to the Council as to the sufficiency of the examina-

tions conducted by the several licensing bodies, as tests of the candidates' fitness to obtain the respective qualifications.

8. That the reports of the visitors shall be forwarded, with as little delay as possible, to the registrar, who shall lay them before the Executive Committee, or the President, in the intervals of the meetings of the Committee.

9. That the Executive Committee, or the President, shall forward the reports of the visitors to the several licensing bodies, to which such reports refer, for their consideration, with a request that the several bodies will make such observations and remarks thereon as they may think necessary, and forward the same with as little delay as possible to the registrar.

10. That the reports of the visitors, and the remarks and observations upon them, shall not be made public until after they have been submitted to a meeting of the General Medical Council.

11. That a special minute book, in respect of the visitations of the examinations, be kept by the registrar of the General Council.

SATURDAY, JUNE 3.

The Executive Committee was elected—Dr. Wood, Dr. Humphry, Dr. Quain, Dr. A. Smith, Mr. Simon, Dr. Pitman.

Moved.—That the Council resolve itself into committee to consider the reports of committees on Parliamentary Bills.

MR. RUSSELL GURNEY'S BILL.

Dr. Thomson: We have left for our consideration sections 3, 4, and 5, which went to the committee for reconsideration.

Sec. 3 refers to the Bill to be introduced by Mr. Russell Gurney. This Bill, as it would appear, is extremely simple, but yet it suggests a very important subject for the consideration of the Council. The committee have felt a great desire not to raise any questions upon which the Council has already expressed any decided opinions. The first thing the committee has therefore done is to refer to the opinion expressed last year. I will read the first paragraph, and will move the adoption of that part of the report.

Section 3. "The committee recommended that the General Medical Council in answer to the request of the Lord President of the Council, that they would give an opinion on the Bill introduced by Mr. Russell Gurney 'to remove restrictions on the granting of qualifications for registration under the Medical Act on the ground of sex,' beg in the outset to refer to the resolutions adopted by them on June 26th, 1875, on the general question of the admission of women to the medical profession. A copy of these resolutions is again sent for the information of the Lord President."

This Sir, leads us a step further than that of last year, but it is quite impossible for the Council to shrink from what is conveyed in this Bill. Doubtless it would be desirable for the Council to shelter themselves under what has been already expressed, and avoid going further. I hope, however, the Council will see the propriety of taking up the point raised by the Bill and expressing a decided opinion upon the matter. The opinion expressed last year was very guarded, but, I think it received the approval of the profession throughout the country. It was just, for it was not for us to debar women from entering the profession, nor those persons who wish to be attended by women from carrying out their desires. I think now it is right that this Council should offer an opinion upon this Bill. I am aware of the embarrassing questions. I am not sanguine of the number who will enter the profession; I should regret it if a large number of women entered, further, I think we shall all be agreed that the joint education of the two sexes would be highly objectionable. I am sure that the Council will very soon be called upon to express an opinion upon how they shall be educated. The question of hospital instruction for women is a practical point, creating the greatest difficulty, and which we shall be called upon to consider. I do not go so far as many in my notion of the disabilities of women in attending the duties of men. Now how can we view in a practical way the education of women in connection with hospitals. It appears to me that there is a way in which we can effect this, and at the same time save the scruples of those who are of a different opinion. It appears to me that the principles of medicine and surgery might be as well taught in females as in males. Such a form of education might be in accordance with the requirements of the Council. Still the committee have carefully avoided making any suggestions which might meet with decided opposition on the part of the Council. I would now move the adoption of the 2nd, 3rd, and 4th Clause of section 3:

"The Council have been advised that Clause 1 of Mr. Russell Gurney's Bill, as at present worded, might render it compulsory on the bodies mentioned in Schedule [A] to the Medical Act, to grant their respective qualification to all persons without distinction of sex.

"The Lord President will observe that, if the Bill operated in this way, it would be against the opinion expressed by the Medical Council in the resolutions of last year, that it is undesirable to interfere with the free action of the Universities and corporations in this matter; and moreover, the Council are informed that Mr. Russell Gurney has no intention that the measure should be compulsory.

"The Council would therefore suggest that Clause 1 should be so amended as to make it quite clear that the exercise of the extended powers which it is proposed to grant would be at the discretion of the bodies concerned, and not obligatory. The Council also are of opinion that the qualifications conferred should not, except at the further discretion of the bodies, carry with them any right to take part in the Government of the Universities or Corporations, or any right or privilege beyond that of registration with a view to the practice of the medical profession."

From these it is clear that the committee see no reason to prohibit those corporations which are willing so to do, to admit women to their examination, but they do see reason why the Bill should not be compulsory upon the examining bodies. They therefore suggest an alteration in the wording of the Bill (clause.) Again, Sir, when a person is qualified, *i.e.*, has received the degree from one of the universities, he or she will have a vote.

Dr. Humphry: I do not think the clauses proposed really carry out the intentions indicated in the able speech of Dr. Thomson, nor do they cover that which is required. Under that Bill it will still be quite impossible for many universities to grant a licence to practise to women, for they cannot grant the degree, and without it they can give no power to practise. It seems to me, I think, something more is absolutely required if women are to receive a licence to practise. I would therefore propose an amendment:—

"That the following words be inserted in place of the Fourth Clause of Section Third."

"The Council would suggest that the object contemplated by the Bill might be attained by enabling any of the licensing bodies mentioned in Schedule [A] of the Medical Act to grant a qualification for admission to the Register to men or women, in addition to the qualifications specified in that Act. But the granting of such additional qualifications should be at the discretion of the bodies concerned, and not obligatory; and that such additional qualifications should not, except at the further discretion of the bodies, carry with it any right to take part in the Government of the universities or corporations, or any right or privilege beyond that of registration with a view to the practice of the medical profession. Further, that the courses of study, and the examinations for such additional qualifications should be under the supervision and control of the Medical Council, in the same manner as the courses of study and examination for the existing qualifications now are."

The real proposal is that there shall be an additional qualification—a "licence to practise"—apart from all existing examinations, and yet entirely at the discretion of the several corporations. We must recollect we have expressed an opinion that women should not be debarred from practising. It therefore behoves us to open the

way. By this Bill, at least, four universities and the College of Surgeons could not examine women.

Dr. Thompson: I have consulted two lawyers, and they are of opinion the corporations would be enabled to admit without distinction of sex.

Dr. Humphry: I maintain that no Body can grant a licence to practise except by granting their diploma or degree, and if that degree or diploma is granted it confers on women, as on men, all the rights of that special degree. Now, seeing that our profession is not sufficiently attracting to men; when you consider that our profession is guarded by a severe education, its arduousness, its unthankful labour, its inadequate remuneration—when you consider that the members of the profession are not sufficiently numerous to supply the requirements of the public.

Dr. A. Wood: That question is not before us. The question here is Mr. Russell Gurney's Bill, and Mr. Russell Gurney is satisfied that it is sufficient in order to admit women into the profession. It is not our duty to suggest how women may be admitted into the profession. It is our duty only to consider the Bill put before us, to show how it will work, to make the best of a bad bargain, and to mitigate the evils that must fall upon the profession. Dr. Humphry is more in favour of admitting women than Mr. Russell Gurney himself.

Mr. Lister: We have already a sufficient number of titles; most people think too many. One serious objection to this proposal is that it would change the whole character of the profesion. The Universities, supposed to stimulate and to carry out the highest form of education, suddenly opening their doors to a minimum examination for admission of women. It seems to me that if the Universities take part in this matter at all, it is desirable they should require a B.A. from women as well as men. If there is the will to admit women, this Bill is the power, but they must be in exactly the same position as men. Now Dr. Humphry says the College of Surgeons cannot admit women; it can be done; but the objection is that if a woman becomes a member she can also become a fellow and take part in the government of the College, to obviate which the clause of the Committee's report is arranged—to prevent them from taking part in the government of those Universities or Corporations. By this Bill a University, if disposed, can at once degrade itself to a mere licensing body.

Dr. Acland: I hold a letter from Mr. Russell Gurney stating that it was not intended to *compel* bodies to open their examinations. Mr. Ouvry's opinion is that it would be compulsory, but on further communication with Mr. Russell Gurney it is quite certain that such is not his intention, and he would be very glad to admit any words which shall make the objects of the Bill evident. If it be the decision of the Council, I think they may introduce a clause or suggest words, for I am certain that Mr. Russell Gurney has no desire to gain his object by any back way.

Dr. Rolleston: I entirely agree with Dr. Humphry's amendment. It is only the same amendment as mine introduced on Wednesday last. I most emphatically demur to Dr. A. Wood's statement that we have only to consider the Bill; we have to consider the rights of the public. I may say again we are not here to protect the rights and privileges of the Universities. This is a matter of expediency, and in the long run of justice. Mr. Lister talks of degrading the University. Justice is no degradation, and it becomes our duty to do justice. The question is becoming a public matter. In refusing firmly to entertain this question we fall behind public opinion, and if we fall behind public opinion we shall be told vey plainly.

Dr. Thompson: As Professor Humphry accepts clauses 2 and 3, I would move that they be adopted. (The two clauses were put to the vote and carried). Dr. Humphry's amendment is not new to the committee. They have considered it, but they fear that such a clause would raise new issues. In the whole of the matter I wish to add the committee had the able assistance of Mr. Ouvry.

Mr. Simon: I would take exception to the amendment. This amendment rather complicates the question. Professor Humphry means that the Bodies should give a qualification without distinction of sex. If it were to give a qualification with distinction of sex I could understand, but surely we do not want an extra qualification for men, and especially as such is not required in the universities. I could understand the examination on new subjects, but certainly not as now proposed. Coming in as a new member, and having to vote on this question, I found myself hampered by the fact that I differ from the conclusion of last year. A thoroughly incomplete answer was given last year. I read in the debates that member after member was of opinion that the profession was not fitted for women, but yet they ruled that "they were not prepared to say they should be debarred from it." What a distance between these two views. Is it or is it not to be announced that, subject to the test of examination, women, equally with men, are fitted for the profession? If such were put I would vote, no. We do not think they should be excluded by law, but we do think they are not fit to practise all parts of the profession. We should agree to something after Dr. Humphry's amendment, that an examination should be instituted, not without distinction of sex, but with distinction of sex. Now here is the point, a difference that I have before pointed out, are we of opinion that women ought to be admitted to the profession. If the Council answer that women ought to be I cannot express my astonishment at the remarks made by some of the members. Dr. Rolleston said that Mr. Russell Gurney's Bill may be safely recommended. The seconder of his motion, speaking strongly of the incapacity of women of their physical disabilities, &c., yet seconds the safe recommendation of the Bill which will enable all women of all physical characters to be admitted to the profession. With regard to the education of women, I demur from the statement that this will come before us. There is such a thing as a law of supply and demand, and I have no doubt such will be arranged apart from us. If Dr. Humphry would withdraw that part which relates to sex, so as to enable the bodies to grant a qualification for the admission to the register *with* distinction of sex, the amendment would deserve to be fully considered by the Council.

Dr. Humphry's amendment was then put and lost, the proposer and seconder only voting in its favour.

The original motion was then put and carried, that clause 4 should stand.

REGISTRATION OF CERTIFICATES IN MIDWIFERY.

Dr. Thomson: I will read section 4 and move its adoption.

Section 4.—"By the communications from the Royal College of Surgeons of England and the Obstetrical Society of London, the question is raised as to the propriety of the registration of midwifery certificates, independently of qualifications to practise medicine and surgery. The committee regard it as a serious error in the Medical Act that holders, whether male or female, of such independent midwifery certificates as may be granted under their charters by the Royal College of Surgeons of England, the King and Queen's College of Physicians in Ireland, and the Royal College of Surgeons in Ireland are entitled to be registered under the Medical Act merely on such certificates. The committee therefore are of opinion that it is desirable that this error of the Medical Act, which is calculated to be injurious to the public interests, should be corrected by legislation."

I think the opinion is quite unanimous that the examination for the License in Midwifery is not a sufficient test of a medical education to be admitted on the register. No one will be inclined to defend that such partial qualifications should be universally placed upon the Register; though perhaps there may be some occasions when such a qualification might admit women to the register.

Mr. Simon: I am willing to second it, but I think it needs further observation. Although I think separate midwifery qualifications objectionable, yet I quite think that it is in this direction that a mistake is to be corrected. If you watch public opinion you will see that in reference to the cause of the women, many people think that no doubt there are certain parts of the profession that can be well taken in hand by women. Though I say that I have a very strong objection to women being admitted to general surgical and medical practice, I do desire to see them receive some qualification which shall enable them to practise in this branch, and in the nursery branch of the profession. We know that there are enthusiasts who fight as a matter of principle; perhaps they might be dissatisfied with such an arrangement, but we might be satisfied in putting our opinion before the Government. I should be glad if the matter were put before a committee during the recess to consider.

Dr. A. Smith: Within the last five years there have been very efficient schools for midwifery instruction in Ireland. Some of the women there educated have come up to the College of Physicians for the licence, and have passed satisfactory examinations.

Dr. A. Wood: Every licence to practise should include an examination in midwifery. There is no doubt that subject is inefficiently taught and examined upon.

Sir D. Corrigan: We have these facts before us—that the College of Surgeons in Ireland gives the licence without any questions in midwifery. Now Dr. Rolleston has observed we have two points—one the protection of the privileges of the profession, and the other the rights of the public. In Paris there are women who make a good income by practising midwifery. Public opinion and public practice have gone ahead of us in this respect. Public opinion has sanctioned what we are now called upon to do. Is it wise for us to fly in the face of public opinion? I don't care about flying in the face of the Ministry, but not in the face of the public. What has been done in Ireland? The Local Government Board are putting educated midwives in authority. In this respect the Board are before the profession. I would propose this amendment:—

"That the following words be added as a rider to the foregoing Section," viz.:—"The Committee further recommend that a separate Register should be instituted for women who have been examined in midwifery, and have obtained certificates from any of the corporate licensing bodies included in Schedule [A] to the Medical Act."

My proposal is not that they should be admitted to the profession or the registration, but that a separate list should be kept. Our duty is not to advocate the placing of women on the Register, but our duty is to discriminate between those bodies who are likely to give certificates to those who are capable, and on the other hand, those bodies who are likely to sell them. I am speaking in plain words, but such I know to be the case, that in some places *incapable persons* are capable of obtaining certificates of proficiency. In the King and Queen's College College of Physicians any woman may come, but she receives a testing examination; many such have gone to India and other places and have done good service. But women obtain certificates of proficiency from lying-in hospitals and other hospitals which can supply an article of sale. I would then move that an addition be made to the clause, that the Council would recommend that a separate Register be instituted for women who have been examined in midwifery, and have received certificates from any of the corporate licensing bodies included in Schedule A.

Section 4 was carried with the understanding that Sir Dominic Cor-rigan's addition should be put as a separate motion.

Dr. Rolleston: If this is merely the practice of midwifery I entirely demur. I say most distinctly that this will not meet the circumstances of the case. I say that many who are not likely to be mothers have demanded women shall be educated and qualified to attend women Women's diseases must be added to the practice of midwifery.

Dr. Thomson: I have no doubt that all the diseases that Dr. Rolleston refers to could be treated by women with this certificate, but I do think that it is not our enterprise nor desire to make it appear that women are qualified to practise other branches of the profession than midwifery.

Mr. Simon: The feeling is popular that the midwife should attend midwifery only. I think it would be difficult to graft on to the *sage femme* the licence which should belong to higher form of educations. If, as I said before, the Executive consider the matter, the subject might be brought up in two sections—1st, the ordinary midwife or *sage femme*, and, 2ndly, when women should be admitted to the Register or to a special register as practitioners in those departments in which we may reasonably suppose they can acquire an efficient knowledge. I think on this the Council will have to express itself more explicitly. The true position will lie between the two extreme views. Those who would prohibit women from doing anything, and those who, on the other hand, run enthusiastically in favour of women's rights, &c.

Sir D. Corrigan: In reply I would say I objected to the additional words of diseases of women. What diseases of women do you mean?—hernia and stone in the bladder, and the thousand other diseases? I maintain that parturition is not a disease. The midwife is required to sit by and see to a function which may from time to time require aid. She is to sit by and see that nothing goes wrong.

Sir Dominic Corrigan's motion, seconded by Dr. A. Smith, was carried.

Owing to the lengthy and important debates held during this week we are unable to refer to the discussions which occupied the Council during Saturday and Monday.

THE plague is said to be fast diminishing in the neighbourhood of Bagdad.

MRS. MINA JURY, the notorious thief who generally selected the houses of medical men for her operations, was last week sentenced to seven years' penal servitude.

MR. VANCE, the medical student who gave instructions to a married lady how she might commit suicide painlessly and without suspicion, was last week sentenced at Newgate to eighteen months' imprisonment, the woman herself being let off with six months' incarceration.

The Influence of Nitrobenzol in Causing the Appearance of Sugar in the Urine.

(Dr. V. Mering: *Centralblatt für die Med. Wissenschaften*, No. 55, 1875.)

DR. EWALD asserted in No. 52, 1873, of this journal, that after the administration of nitrobenzol to dogs and rabbits he had found in their urine a large quantity of a body which had the property of reducing the oxide of copper. This substance reduced an alkaline solution of copper, and, according to him, when treated with yeast under the proper precautions was capable of fermentation. From the investigations which he has been making for some time, Dr. V. M. is certain that the substance which is excreted in the urine under the circumstances given above is not sugar. This substance he finds capable of reducing an alkaline solution of copper, but when treated with due precaution with yeast is not capable of fermentation. It is also deserving of special mention that this substance deflects light towards the left, which, as is well known, is diametrically opposed to the influence of grape sugar.

WEDNESDAY, JUNE 7, 1876.

THE CONJOINT SCHEME.

At the meeting of the Council this year no conjoint scheme was presented for consideration, and a subject which is now foremost in the minds of all the leading members of the profession would have al together escaped discussion had not Sir William Gull proposed a resolulution to the effect that the Council express their regret that up to this time, and after so long delay, no scheme for a Conjoint Board for England, Scotland, or Ireland has yet been put in operation. The Council further desire urgently to press this matter of conjoint examinations upon the bodies whose duties it is to arrange and supervise the medical examinations in the several divisions of the kingdom.

Notwithstanding a very determined opposition on the part of the Scotch members, this motion was carried by a majority of fifteen to six; and thus we have again a strong expression of opinion on the part of the General Medical Council that, for the advancement of science, and the benefit of the public, as well as for the advantage of the profession, there should be at once instituted an examination, the standard of which shall be defined, and in which all the examining bodies should co-operate.

In the discussion to which this motion gave rise, each speaker took a different view of the text upon which he arranged his arguments. The object of the resolution was to urge co-operation upon the several examining bodies in order to obtain some uniform examination; but the Scotch members, aided by two Irish members, were desirous of negativing the resolution apparently on the ground that, if a Conjoint Board should be formed, students would find it unnecessary to graduate, and the Scotch Universities would consequently suffer. Nevertheless the whole Council were of opinion that co-operation in some form or another was an absolute necessity for improving the standard of the minimum examination.

The arguments consequently became somewhat vague and undecided; for whilst one raised objections to the one portal system, another objected to the Universities associating themselves in a Conjoint Board, and a third looked upon the attempt to form a Conjoint Board as futile, because previous schemes had proved failures.

The objections raised against the one portal system were, to say the least, frivolous; but the discussion showed plainly that no conjoint scheme will be developed in either Ireland or Scotland unless forced by the success of a scheme first tried in England.

In an early stage of the debate, so evidently were the speeches directed against conjunction, that Professor Humphry, fearing the majority would by negativing the motion rule that Conjoint Boards were unnecessary, proposed an amendment urging the co-operation of the licensing bodies in order to secure that persons admitted to the Register should be properly tested in medicine, surgery, midwifery, and other subjects deemed essential by the Council. Subsequent speeches, however, tended to show that whatever might be the decision of the Council, co-operation in England could not be prevented; and the result of the division proved that such fears were unfounded, all the English and four of the Irish members voting in favour of the motion.

It will be heard with satisfaction that the Council by carrying this resolution have again pressed the matter upon the licensing bodies of framing a conjoint scheme; for it cannot be doubted that at the present time the public spirit, the Universities, and Corporations all tend to such; and though the English scheme, which has lately been so well worked out, and which has been accepted by all the examining bodies of England almost in its entirety, is not yet quite fitted to be put in operation; it is certain that the time is not far distant when a combination of the licensing bodies in England will have been effected, and a death-blow dealt to the strangely imperfect duplicate examinations by which the College of Physicians and the College of Surgeons now quiet their conscience, the one giving a frivolous examition in surgery and the other in medicine.

NON-ACADEMIC M.D.'s.

A memorial addressed to the General Medical Council illustrates forcibly the appetite of the profession for the title of M.D., and the anxiety of a certain class to decorate themselves with that *imprimatur* without the trouble of obtaining it in the regular way. The memorial emanates from certain persons who had gone to the Continent for their Doctorate, and had not undergone any academic course, yet, nevertheless, desired to be admitted to registration, and to the use of the title of Doctor on the same footing as the graduates of the English Universities. The prayer of the memorialists is only an expansion of the claim which the licentiates of Colleges of Physicians have put forward to be permitted to call themselves Doctor and M.D., which demand, though approved of by a Committee of the London College of Physicians, was very properly rejected by the College at large. It was quite evident that the Medical Council was bound to refuse the prayer of the petition on other grounds than those held by the Universities, for it is forbidden by the Medical Act to put

on the Register any degrees but those granted by the British and Irish licensing bodies, and it is, moreover, charged with a supervision of curicula and examinations which it would be impossible to carry out in respect of Foreign Universities. But the plain fact is, that if the registration of non-academic M.D's. were permitted, the move would defeat its own object, and in a few years the profession would cease to covet the Doctorate, and there would no longer be a demand for the degree. The M.D. is no better guarantee of professionl attainments than the licence of a College of Physicians, nor does it confer a higher rank upon the holder in the practice of medicine, but it does usually, and ought in all cases, carry with it the distinction of a liberal education, and of a prolonged course of literary study. A Doctor of Medicine is presumed to be not only a medical practitioner, which he might be without an M.D., but also a gentleman and a man of education, and it is this latter character which renders the Doctorate an object of desire. If it were granted, as it is by the Foreign Universities, and the Queen's University in Ireland, without any genuine course of academic study, it would not be sought for by those who wished for distinction in the profession unless they were permitted to attach to their names some mark which would indicate that they had obtained the degree after a full course of academic study. It is, we hold, a false pretence for a College or a University to assume to grant a Doctorate in Medicine without a complete course of study in arts, and Universities which do so cannot hope to be classed with others whose graduates are presumably persons of education as well as physicians.

FASTING GIRLS.

ANOTHER of these incredible stories, which occasionally crop up as examples of the gullibility of human nature, is reported by Dr. J. N. Norris, of Birmingham, Iowa, in the *Medical and Surgical Reporter* (Philadelphia), April 1, 1876. Indeed, no better day than that of "All Fools" could have been selected for the publication of the supposed facts of such a case. We do not at all impugn Dr. Norris's good faith in the matter, however little we are impressed with the solidity of his judgment, or his capability of weighing evidence in the balance of truth.

These supposed facts of the case under notice may be briefly stated as follows: Eliza Egbert, æt. 11, the subject of diabetes mellitus, *complicated by chorea and hysteria*, "utterly refused all food May 10th, 1875." Complete abstinence supervened "on an already debilitated and anæmic condition of the system, reduced by a protracted and wasting disease." No threats or entreaties on the part of either the mother or doctor could induce her to take anything *beyond a little cold water*. Dr. Norris assures us that not a grain of nourishment or medicine was taken for the space of *fifty-nine days and nights ! ! !* and that for days together not even water was taken. He also states his conviction that there was no collusion between the mother and the child, based upon the fact that he has often heard the former implore her daughter with tears in her eyes "just to taste" something in the shape of food.

Since the case terminated fatally, we are quite prepared to admit that the actual amount of food taken may have been very small indeed, and very probably, since there does not appear to have been anything to gain by deception in the matter, the mother may have been innocent of intentional deceit; amongst the lower orders, at least, our experience is, that they are at all times ready to exaggerate their statements as to the condition of a patient, and again the mother herself may have been the subject of deception. It is unnecessary however to dilate much on the matter. Common sense teaches us the impossibility of a weak, disease-wasted child existing for almost *two months* upon a little cold water; and what is wanting to establish the deductions of "common sense" Dr. Norris himself has kindly supplied in his further statement of the condition of his patient. "During all this time nothing that could be called delirium was at any time present. Down to within three days of her death *she seemed to scrutinise closely all our movements, actions, and conversation, especially when the latter had any reference to her condition.* For days together during the last two months of her sickness she would persistently refuse to answer when spoken to, or to ask for anything she desired, but communicated her wishes by signs and motions, though I am convinced that she could at any time have conversed intelligently, *had she so willed.*' Here we have ample evidence of that depraved mental condition of patients affected with hysteria, in which there is a morbid craving to excite and attract sympathy at almost any cost, and which in this instance, no doubt, was stimulated by the wonder excited, and we dare say freely expressed by her mother, Dr. Norris, and all who saw her. Dr. Norris states that "the bowels were relieved about once a week by the use of enemata, *the appearance of the dejections being quite normal.* Surely this fact ought to have excited his suspicions as to the existence of *perfect abstinence.* We believe that removal to healthier moral influences, the care of a firm, unsympathising, judicious nurse, the administration of nutritive enema, with or without the patient's consent, and an absence of all curiosity as to the supposed interest of her state, would have been attended by very different results. There is one remark of some interest to which we would direct attention in Dr. Norris's report, viz., "the diabetic symptoms gradually disappeared after the fast commenced, so that three weeks before she died the urine was reduced to much less than the normal quantity."

Notes on Current Topics.

Sanitary Trains.

A PROJECT has been set on foot in Austro-Hungary to establish sanitary trains. A Royal Commission has come to an arrangement with the representatives of the different railway companies, whereby the latter undertake to construct, and to maintain in a working condition, a certain number of "sanitary trains," adapted specially for the transporting of sick and wounded men. Each train will consist of one second-class passenger carriage, one third-class passenger carriage, one luggage waggon to be em-

ployed as a store for medicine, surgical instruments, &c., one waggon fitted up as a kitchen, a covered waggon to be employed as a provision store, and thirteen covered luggage waggons for the forwarding of the sick and wounded. Each train will carry 104 men. The trains are to be constructed by the railway companies in the proportion of two-thirds by Austria, and one-third by Hungary, and are to be maintained as far as possible in a complete state of readiness in time of peace.

Vaccination Case.

Alfred George Roberts, of 16 Rotherfield Street, Islington, was summoned by Mr. John Broome, vaccination officer for the parish of St. Mary, Islington, for not having sent his child to the public vaccination station in order that the arm might be inspected by the medical man and other children vaccinated therefrom. It was proved in evidence that this most important clause in the Vaccination Act had not been complied with at the proper time, and that great inconvenience was likely to arise from such a cause, not only to persons taking their children for vaccination, but also to the officers. In the present case, the defendant having complied with the provisions of the act since the summons was issued, a mitigated penalty of 1s. only was inflicted, with the cost of the summons. The magistrate remarked that these cases were very properly brought before him.

Cruelty, a Characteristic of Man.

At a meeting of the Oxford branch of the Royal Society for the Prevention of Cruelty to Animals, the Bishop of Oxford in moving the adoption of the report referred to the prevention of cruelty to animals as influencing the social life of man. "Cruelty," he said, "was a character, a state of mind and habit of acting, and although now and then a cruel thing might be done in thoughtlessness, the general commission of acts of cruelty indicated a temperament of which cruelty was the characteristic, and it was quite certain where there was cruelty it would not be confined to animals. The temper and character which produced these acts were just as dangerous to man and woman as to the animals whose cases they had particularly in view; and when they had succeeded in repressing acts of cruelty to animals, they should keep under control and in check that temper and character which made homes miserable and led to acts of fatal violence.

Treatment of Stammering.

One of the American papers contains a letter, which appears trustworthy, written by a gentleman who stammered from childhood almost up to manhood, and who gives a very simple remedy for the misfortune:—"Go into a room where you will be quiet and alone, get some book that will interest but not excite you, and sit down and read two hours aloud, to yourself, keeping your teeth together. Do the same thing every two or three days, or once a week if very tiresome, always taking care to read slowly and distinctly, moving the lips but not the teeth. Then, when conversing with others, try to speak as slowly and distinctly as possible, and make up your mind that you will not stammer. The first result was to make my tongue and jaws ache, that is, while I was reading, and the next to make me feel as if something had loosened my talking apparatus, for I could speak with less difficulty immediately. The change was so great that everyone who knew me remarked it. I repeated the remedy every five or six days for a month, and then at longer intervals, until cured."

Experiments with Arsenic.

Some interesting experiments on the localisation of arsenic in the tissues of poisoned animals are described by M. Scolosuboff in the *Bull. de la Soc. Chim.* Dogs can absorb without danger about sixteen times as much arsenic (in proportion to their weight) as would kill a human being. His experiments also prove that arsenic first accumulates in the nervous system, and then passes to the liver and muscles.

Catacombs v. Cremation.

A French engineer, M. de Jugny, proposes a method of disposing of the dead, which, in his opinion, would render cremation, to which there are so many objections quite unnecessary. It consists in constructing vast subterranean galleries, two stages in height. Each gallery is to be divided into compartments formed of very solid hewn stone, each being able to hold a coffin, and so secured that no infiltration or exhalation can take place. The system, it is said, is in action at Naples, to everybody's satisfaction. The expense, carried on over twenty years, will amount to only 400,000 dols. per annum. Calculations show that about ninety acres of land will suffice for the entire population of Paris; and the requisite territory may be obtained underneath the fortifications, and distributed according to the wants of the different parts of the capital.

Ex-officio Governors of Irish Lunatic Asylums.

Mr. Richard Power, the senior member for Waterford last week in the House of Commons put the following question to the Chief Secretary for Ireland:—"Is it true that the Lord Lieutenant and Privy Council of Ireland have issued an order declaring that on any *ex-officio* governor and director of a district asylum ceasing to hold the office by virtue of which he acts as such he shall cease to be a governor and director, and his successor in the office aforesaid shall not be entitled to act as an *ex-officio* governor and director of a district asylum; whether said order is intended to apply to all lunatic asylums in Ireland, and if he would explain to the house why such order had been issued?"

Sir M. H. Beach.—Yes, sir, such an order was issued by the Irish Privy Council on the 26th January last. Technically it applies to all lunatic asylums in Ireland; practically only to eight, for in that number only does it appear that *ex-officio* governors exist. These *ex officio* governors consist of high sheriffs, members of Parliament for counties and boroughs, dignitaries of the Established Church, and in some cases the Mayor of the city or borough where the lunatic asylum is situated. It appeared from inquiries which had been made that the legality of these appointments was very doubtful, and as difficulties were likely to arise, the Privy Council considered it advisable, while confirming all existing appointments, to direct that no gentleman in future hold the appointment of governor solely in virtue of the office or position which he might temporarily occupy.

We look upon this decision of the Irish Executive as extremely unsatisfactory, and much to be regretted. It

has long been the policy of the Irish Lunacy Department to subordinate the boards of governors as far as possible to the Dublin Castle authorities and to their nominee, the resident medical superintendent. One or two of the boards of governors—notably those of Limerick and Maryboro'—have shown too much independence and impatience of inspectorial dictation, and have insisted on reforms which the Castle office has been unwilling to give, and in this line of action the *ex-officio* governors have been prominent. It would seem that the Castle authorities have decided to clip the wings of these contumacious gentlemen, and as we regard the abasement of the District Asylums beneath official control as the greatest misfortune the Irish Lunacy System could meet with, we again express our unqualified regret at the terms of the Chief Secretary's reply.

The Milk of Sulphur Controversy.

THE *Chemist and Druggist* quotes with apparent satisfaction a letter published by a druggist in the *Manchester Examiner* as an apology for the adulteration of "Milk of Sulpher" with plaster of paris. The writer says:—There are two preparations of sulphur used medicinally—sublimated and precipitated. The former is prepared by heating sulphur to 500° or 600° and collecting the sublimated particles, which is known as flour of sulphur. The second is made by boiling flour of sulphur with slaked lime in water, and afterwards precipitating the sulphur by adding an acid. When muriatic acid is used, in conformity with the Pharmacopœia, pure sulphur is the result. For many generations sulphuric acid has been employed instead of muriatic, resulting in the precipitation of a quantity of sulphate of lime with the sulphur. This is the article known as milk of sulphur, which has been condemned by the Salford public analyst. The writer omits to say why it is that "for many generations sulphuric acid has been employed instead of muriatic." It is hardly necessary to say that it is so employed for a fraudulent purpose, because not only is it itself slightly cheaper than the hydrochloric acid, but the sulphate of lime goes to make up the weight of the precipitate. A pound of flour of sulphur dissolved in lime mixture will yield a much greater weight of precipitate, when treated with sulphuric, than with muriatic acid; the bulk of the precipitate as the druggist well knows and intends, being plaster of paris, which is not contained at all in the precipitate from muriatic acid. The writer goes on to say that the adulterated article is much more easily swallowed than the pure sulphur, and that a quantity of plaster of paris does no one any harm, with which propositions the public have nothing whatever to do. They ask for sulphur and they should recieve nothing else. The chemist may, if he pleases, explain the advantages of the sulphate of lime mixture either by label or verbally, and if it has these qualities no doubt it will be bought in preference to the pure sulphur, but he has no right to substitute anything for the article purchased, and to do so is roguery, no matter how beneficial to the victim that roguery may be.

We observe with satisfaction that a conviction has been obtained against a druggist in a similar case, and that a case has been stated for decision in the superior courts, when the question will be set at rest by the judgment of a competent tribunal.

Personation.

THE *Gazette Médicale de Paris* gives an amusing account of the personation of M. Sichel, the Parisian ophthalmologist, by a Jew named Levi. M. Sichel, who has inherited his father's celebrity as an oculist, has of late years been much annoyed by persons assuming his name, traversing the provinces, and giving advice on diseases of the eye, under pretext of selling spectacles. In 1871 and 1872 he endeavoured to bring one of these persons to justice, and obtained several judgments against him, but always found he had decamped from the towns in which these had been delivered. At last, in 1873, he was caught hold of at Avignon, and was severely punished. M. Sichel thought that henceforth he might consider himself freed from the nuisance he had so long suffered, but in 1875 he learned that another Dr. Sichel had started up, and was committing numerous rogueries in his name—sometimes declaring that he was Dr. Sichel's brother, and at others that he was the Doctor himself. Latterly he was trying his fortune at Havre, where a former assistant of Dr. Sichel's had him arrested. He was found to be a brother of the Levi who was formerly condemned. Once taken, he was dealt with sharply enough, being sentenced to two years' imprisonment and a fine of 600fr. He was also condemned to pay Dr. Sichel 1,000fr. damages, and to advertise his condemnation in a great number of the Paris and provincial newspapers.

The same attempt at personation was perpetrated in Ireland some years ago by a man who gave out that he was a son of Dr. Arthur Jacob, the well-known oculist of Dublin. He traversed a great part of the Irish provinces, selling spectacles to the unwary, but was eventually exposed by a Limerick clergyman who was also named Jacob, and whose name he had used in the locality. This gentleman sent a letter to the papers, and forthwith received notice of an action from the swindler. It is needless to say that the action never went on, and shortly afterwards the personator disappeared.

The Prisons of England.

THE Home Secretary stated in the House last week that it is the intention of the Government to take over the management and expense of all the prisons of England. At present there are 116 of them, many very small, while the expense of keeping them open is excedindly great. The cost in the aggregate is £549,000 a-year. Mr. Cross believes by closing fifty of these prisons, and equalising the cost of maintenance of the remainder, which varies from £15 to £150 per prisoner, the whole expenditure can be well reduced to £385,000 a-year, with an increasing revenue from prison labour. Moreover, a much needed uniformity of discipline and punishment will be more effectually enforced. Prison discipline is certainly not a local affair; but it is urged by the opponents of the change that this is only intended to relieve the rate-payer at the cost of the payers of income-tax.

The Surgeon-Oculist to the Queen in Ireland.

THE *Students' Journal and Hospital Gazette*, commenting in a deprecatory tone upon the recent appointment, says :—

"How these things are managed is a mystery we shall not endeavour to elucidate; practically it is a matter of little consequence who is oculist to the Queen in Ireland. She is not likely to visit Ireland again, and provision has been made in this country for any surgical interference that may be necessary to Her Majesty's eyes."

We are obliged to differ with this opinion, and to deprecate the inference that it is a matter of indifference to the profession whether or not Irish surgical distinctions are distributed to the most deserving. The Surgeoncies to Her Majesty are not—in either England or Ireland—household offices about the Queen's person. They are decorations with which Her Majesty is presumed to distinguish the leading surgeons of each division of the kingdom; none the less honours because they involve no actual attendance on Her Majesty, and to be conferred not as Her Majesty would select a menial, but as the Sovereign would distinguish a meritorious subject. We cannot subscribe to the theory that, however bad an appointment may be, it is good enough for Irish doctors, and we submit that it would be a very fitting employment for our contemporaries to inquire into the method by which these distinctions are given away. If they did so they might find that the same contemptuous disregard of Irish Surgery and its interests which is suggested in the foregoing quotation exists in the mind of the adviser of Her Majesty.

Increases of Salary to the Visiting Physicians of Irish Lunatic Asylums.

THE following Order in Council has been issued, enabling Boards of Governors to make increases of salary to their visiting physicians when deserved.

BY THE LORD-LIEUTENANT AND PRIVY COUNCIL OF IRELAND.

ABERCORN.

WHEREAS the Lord-Lieutenant and Privy Council of Ireland did by an order dated the 23rd of February, 1874, establish certain Rules and Regulations for the good conduct and management of the several District Lunatic Asylums in Ireland:

And whereas certain of the said Rules and Regulations relate to the office of Consulting and Visiting Physician to the said Asylums:

And whereas it is expedient to make further regulations with respect to the said office:

Now we, the Lord-Lieutenant, by and with the advice of the Privy Council of Ireland, and by virtue of the powers given unto us by the statutes in that case made and provided, do hereby order and direct that it shall be lawful for the Lord-Lieutenant in Council to increase the salary of any consulting and visiting physician who may have served eight years in any District Lunatic Asylum in Ireland to the satisfaction of the Board of Governors, upon the recommendation of such Board and of the Inspector, such increase not to exceed in any case 25 per cent. of the annual salary payable to such officer at the date of this order.

M. E. HICKS BEACH. WILLIAM BROOKE.
J. WHITESIDE, C.J. S. WOULFE FLANAGAN.
ROBERT R. WARREN. J. D. FITZGERALD.
FRED. SHAW. HENRY ORMSBY.
HEDGES EYRE CHATTERTON.

We believe that this order was made upon the repeated and persistent representations of one Board of Governors, which representations were several times reiterated by the Board and rejected by the Inspectors, and, at length, were acceded to.

Female Medical Practitioners.

A BILL has been introduced by Mr. Russell Gurney bearing the above title, to remove restrictions in the granting qualidcations for registration of women under the Medical Act.

The Pollution of Rivers.

THE head of the Local Government Board, Mr. Sclater Booth, has promised to introduce a bill, soon after the Whitsuntide holidays, to prevent the pollution of rivers.

The Vivisection Bill.

THE Duke of Richmond has stated that he could not proceed with the Vivisection Bill, as he had recently received some very important communications from persons interested in the subject, and he could not yet decide what course to adopt with reference to the Bill.

The Charing Cross Hospital.

THE annual report of the Charing Cross Hospital has just reached us, and from its pages we gather that the institution is in a satisfactory and prosperous condition. During the year 1,181 in-patients were admitted, and 14,914 out-patients. The large number of 4,153 cases of accident received attention and treatment, and at a total cost of £18,978. The average cost of each bed occupied strikes us as being rather high—£98—but doubtless subscribers will see that the money was well spent in providing everything necessary for the cure of the patients. The increased expenditure is, however, accounted for in another way: through a portion of the year the hospital has been partially closed for substantial repairs and improvements. The warming, ventilation, and other additions will, when completed, afford an increased amount of comfort and accommodation. By the rearrangement of the wards, and the addition of a new third story, it is understood that the hospital will soon have 200 beds in use. Appended to the report is the valuable and interesting details of the medical and surgical registrars, and in which we find the particular of patients under treatment the various diseases and injuries for which they were admitted, and the termination of the cases in recovery, relief, or death.

Cruelty to Animals.

As we listened to the speech of Sir Dominic Corrigan in the Medical Council last week on the subject of Cruelty to Animals, we could not help wishing that some of the representatives of the general public, and of those well-intentioned ladies and gentlemen who are spending their time and money in agitation for the abolition of physiological experiments on animals were also present to hear an exposition of some of the every-day cruelties inflicted by the world of fashion. The skinning of golden wrens and other birds for their plumage, lopping the tail of the fox, and plucking the feathers from the ostrich, all for the purposes of fashion, and to enable the same well-intentioned ladies to disport themselves in,

careless or forgetful it may be, or perhaps in ignorance that in each case the poor little wren, as well as the bird of larger dimensions, were alive when the operation was performed upon them ; the cramming of fowls, turkeys, and ducks, and its effects upon the œsophagus of these birds, so that the poor wretches were unable to bend their necks to pick up a grain of corn, that gourmands might indulge in *pâté de foie gras;* cock-tail horses for hunting, which were kept in the greatest torture for a fortnight with their tails tied erect to a heavy weight over the stable beam ; the torture of pigeons at Hurlingham, by having their tails cut off at the joint previous to being let loose from the trap, that the poor birds might not use that lever which their Creator had given them, thus compelling them to fly perfectly straight for the cruel sport of those who indulged in it, and the pleasure of ladies of distinction who came to see the butchery – these and a host of other acts of wanton cruelty were recounted by Sir Dominic, who protested that the medical profession should alone be selected for legislation, when cruelty of far baser descriptions were indulged in on all sides by the general public than was ever dreamed of by the physiologist in his legitimate investigations. Let us, concluded the speaker, return blow for blow, and if legislation be necessary on the subject, let it be treated in regard to its relations to society at large.

Medicine under a Cloud.

The *Toronto Globe* of the 17th of April, reveals an incredible state of anarchy in the medical world of Canada. It appears that the local Medical Council deputed certain persons to hold examinations in connection with the College of Physicians and Surgeons of Ontario. An exact narrative of what followed is not forthcoming, but it appears that—say after the meeting of the court, a *Toronto* newspaper denounced the examination—examiners and examined in terms of violent indignation, stating plainly that "the medical men appointed as examiners were in a state of beastly intoxication," and that the "students kept up a row, and manifested their disapproval and disgust at the continued drunkenness of certain members of the Board of Examiners by singing and howling and threatening to break down the doors."

The *Toronto Globe* says the Examiners had been engaged all Thursday in the oral examination of the applicants for license whose written papers had not been found up to the required standard, and continued their labours until past three o'clock on Friday morning. On leaving the University they were assailed by a shower of eggs, snowballs, and stones, and though no serious damage was done to any of them, their clothing suffered, and they were doubtless much shocked by the shameful treatment they received. While it strongly condemns this conduct on the part of the students, the *Globe* offers some excuse for them in the statement that "some of them had been kept in town for days by the neglect of their duties by some of the examiners—neglect arising from a disgraceful cause—and we believe there is foundation for this charge. To this treatment the Chairman of the Examiners, a Dr. Campbell, offers a denial, as far as the charge of drunkenness is concerned, but another correspondent of the same paper, who signs his name to his letter writes as follows :—

Never perhaps did a respectable body of young men, presenting themselves for examination, have greater cause for feeling humiliated—yea, even degraded in their own eyes—than have the gentlemen who appear during the past few days before the "Examining Body" of the Council of Physicians and Surgeons of Ontario—gentlemen many of them graduates in either Arts or Medicine in the Universities of Toronto, Kingston, Montreal, and cities of the United States.

With reference to the first ground of complaint, when an examiner's department, either during a written or oral examination, or in the interval of such examinations, is similar to that of a man after he has been imbibing too freely of intoxicating liquor, and acting and speaking as if he considered himself the repository of all knowledge, the conclusion would be that such a man was really actuated by the operations of too much intoxicating liquor, and when such conclusion is very generally arrived at by the mass of the examined, it is not likely to be far from correct.

Again, when a student appearing before the whole Board of Examiners answers questions, and is informed that they are correct by one examiner, while another, bandying oaths, asserts the opposite, he cannot but feel the degradation of such ungentlemanly conduct.

When an examiner submits as one of his questions :—"In removing the parotid gland, detail the operation, dangers during and subsequent to its removal, and the duties of the assistant"—(an operation by the way thus alluded to by Prof. Erichsen, of London, England, one of the best of living surgeons in his admirable work on surgery : —"I believe that in most, if not all, the cases in which it is stated that complete removal of this gland has been accomplished, tumours overlying and compressing it have been mistaken for it. It is evident that a diseased parotid could not be removed without the division of the external carotid artery and facial nerve,")—the inference is either that he is acting unfairly, or is himself ignorant of the fact that such an operation is unwarrantable in practice, and hence an unfair question.

Many a student, after years of hard reading and miserly care of his funds, comes up at length to obtain his license, being duly notified that at certain hours he will be expected to undergo his examination upon certain subjects. His means nearly exhausted, he feels anxious to get away at the earliest possible moment and thus escape a rapidly increasing expense, but finds that instead of learning his fate on the day fixed for the same, he is kept waiting for days.

Why the delay? With shame he acknowledges having seen one of his examiners hanging about the bar of a drinking house, while yet the papers subject to his examination are not handed in. Or in the case of another who becomes an obstructionist to business, quarrelsome with his co-examiners, and expresses a desire to pluck each and all, can it be possible that such things existed? I answer yes, and further, that men passed during the sober moments of certain examiners at one time without oral examinations, while others at a later hour of the day, with total results equal or even higher than some of those, were not so fortunate.

This Board of Examiners is—we believe—the outcome of a compromise, which has been in course of arrangement in Canada for some years, under which the homœopaths, electics and every other species of quack in the dominion have been admitted to paternisation with qualified surgeons and to participation in the medico—legislature function of the State.

Correspondence.

POOR-LAW MANSLAUGHTER.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—A terrible cry has gone forth to Heaven for vengeance

against the rich parish of St. George's, Hanover Square. A scandalous act of cruelty has been perpetrated by an officer of the Board of Guardians upon a poor needlewoman, Charlotte Hammond, aged fifty-three, who was suffering in her miserable lodging from an attack of chronic bronchitis. The parish medical officer, it appears, was called to her, and finding her disease greatly aggravated by the combined effects of cold and starvation, sent by the daughter, who was attending her mother, an order upon the relieving officer for a little meat. Failing to obtain this, he subsequently sent an order for beef-tea, both of which were brutally and obstinately refused. In place of bread the poor woman was offered a stone. An order was given to the daughter for her mother's admission to the workhouse, but to this both the doctor and the patient demurred. The poor woman was too weak to be removed, and naturally enough said that "as she was going to die she would rather die at home." In two days she sank and died, and the coroner's jury had no hesitation in returning a verdict of "Death from bronchitis, accelerated by want of nourishment." It is a monstrous thing to find in the richest quarter of London, and at this period of the year, that a poor suffering fellow-creature is condemned to die of starvation by gentlemen holding a high position in society, and professedly acting as *guardians of the poor!* At the coroner's inquest two of the guardians did not hesitate to come forward to support the cruel act of their relieving officer, and sustain him in an act which has resulted in death by starvation of a poor afflicted woman. Mr. Hardcastle and Colonel Scott seem to have a vague notion of their duties to the ratepayers of their parish, otherwise they could never for a moment have given their sanction to the refusal of all relief to Mrs. Hammond, and which was so urgently and humanely made by the medical officer in this distressing case. Colonel Scott had his particular attention called to this poor woman, and he saw with his own eyes the utter destitution of her lodging, and that she was without a morsel of food. Nevertheless, he refused to see the doctor's order carried into effect, and thus the dying woman was condemned to die of starvation.

The *Times* very properly desires to know if the Poor-law Board shall suffer this cruel case of "manslaughter by starvation" to pass over without inquiry, or permit so gross a violation of the law to go unpunished. Will these wise Guardians of St. George's, Hanover Square, be permitted to retain the services of a relieving officer whose undiscriminating harshness will have again to decide cases of life and death, and who in this particular instance, and "in a spirit of savage economy, refused a poor creature a few pints of beef-tea to maintain the bare life within her."

Yours faithfully,

PHILANTHROPIST.

THE PUFF DIRECT.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—It is happily extremely rare for anything having even the semblance of a puff to find a place in the columns of respectable medical journals. Puffs as a rule influence only the ignorant, and have but little effect, unless the reverse of that desired, upon the educated members of the profession, especially when their object is to unduly laud individual practitioners upon whose questionable merits the readers have had ample means of forming an independent judgment. I am sorry to record a glaring exception which occurs in the last issue of one of your contemporaries, which I have reason to know has excited just indignation, and will call forth strong protests. Your readers are aware that there has been recently founded a new society with a high-sounding title, "The Association of Surgeons practising Dental Surgery." It is composed of a clique of practitioners who have assumed a public position as a representative body in direct opposition to the emphatically expressed indignant opinion of those most honoured in their branch of the profession. The proferred membership of the Association has been refused by such of the eminent dental surgeons to whom it has been offered, and in refusing it they have expressed clearly the grounds upon which they object to the new association—grounds which have already been explained in your columns. In spite of this, and with the full knowledge that the Association at most comprises but a few of the number of surgeons practising dental surgery, your contemporary has gone out of its way to recommend in the strongest terms the medical profession and the public to employ "for safety" no dental practitioners but members of the association. This recommendation is supported by many verbose sentences, modelled in the style somewhat of a tradesman's puff, extolling the wonderful and superior knowledge and professional acumen of the members of the Association. When it is remembered that the number of *surgeons* practising dentistry—in contradistinction to dentists holding the diploma in dental surgery—altogether in the United Kingdom does not, if at all, much exceed fifty, it will be seen that the advice of your contemporary would be likely to ensure an enormous accession of practice to the fortunate few members composing the association, if it were likely to be learnt by the public or regarded by the medical profession. Luckily, however, the public do not read the medical papers, and the profession can be trusted to ignore the tendered advice.

The puff, however, appears intended rather more to benefit the one dentist whose name it mentions, than even the few connected with him in the Association, and its style indeed bears strong internal evidence—like so many slightly more vulgar puffs—of its having been, if not concocted, at least inspired by the individual in question. This young gentleman, bearing a name which for two generations has been honoured in the dental profession, is doing a little towards tarnishing its lustre. He has done no work in his speciality of any value (unless the foundation of the association turn out such), but seized with the *cacoëthes scribendi*, and a burning desire for publicity, has rushed into professional print on every occasion upon which there appeared a chance of his inflated sentences obtaining insertion, always taking care to avoid any subject upon which the display of scientific knowledge might be called for and his knowledge tested. The course which he has pursued he will find, however, a mistaken one, and I doubt not that in one respect his dental brethren will find means to demonstrate the fact to him. With regard to your contemporary, I would humbly advise him, for the sake of the honour of medical journalism, to keep a stricter watch over the editorial doings of his "young gentlemen." The insertion of puffs such as that of which I complain, while injuring him, exciting as it may the unfounded suspicion that he has been *nobbled*, will benefit you, since offended supporters will attach themselves probably to other organs; but I should prefer, under all the circumstances, that he make amends for his false step, and promise not to do the like again.

I remain, your obedient servant,

ANTI-HUMBUG.

Literature.

DISEASES OF THE NOSE. (*a*)

THE author of this treatise is well known as an indefatigable worker in several branches of surgery. His previous communications to medical journals and medical societies would lead us to expect that any large work from his hand would be characterised by completeness and a very careful collation of authorities. The subject he has now taken up has more than once been proposed by the Council of the Royal College of Surgeons of England for the Jacksonian Prize—the last time as recently as 1872. Only once has a prize been awarded. That was in 1834, to Mr. Crompton; but his essay has never been printed; nor is there any work with which Mr. Watson's can come into competition. Of course all our surgical, and, indeed, some of our medical text-books, treat of the subject in its several aspects, although but briefly, and much important information is scattered through our periodical literature. The author's task has, then, been no easy one. It involved a good deal of literary research, no little labour at the various museums, where good illustrations of the diseases are to be found, and practical experience to make the most of the materials.

(*a*) "Diseases of the Nose and its Accessory Cavities." By W. Spencer Watson, F.R.C.S. Eng., B.M. Lond.; Surgeon to the Great Northern Hospital; Surgeon to the Royal South London Ophthalmic Hospital, and to the Central London Ophthalmic Hospital; formerly Assistant-Surgeon to King's College Hospital. London: H. K. Lewis. 1875.

To show the extent of the subject, and the manner in which it is treated by the author, we will briefly state the plan of the work. It opens with a sketch of the anatomy and physiology of the nose and nasal fossæ. Then follows a section on rhinoscopy and non-ulcerative affections of the nasal fossæ. Here we must observe that the remarks on rhinoscopy both anterior and posterior are somewhat defective, and indeed almost antiquated, and to the lithographic plate by which this section is illustrated the same criticism may be applied. We are informed, indeed, that all authorities are agreed as to the difficulties of posterior rhinoscopy; but then we are assured that in a number of cases great skill, patience, and judgment will enable us to carry it out with advantage if aided by great self-control on the part of the patient. This is certainly not very encouraging to beginners, who will, in fact, obtain no assistance whatever from our author, and of course the expert rhinoscopist will pass over the brief account of this subject to consult the work on the diseases of the mucous membrane and their treatment, where he will find many useful hints. The plate we have mentioned contains eight distinct figures, but none of them are original, three being copied from Czermak, three from Giraldès, and two from Meyer. Those after Czermak may really be looked upon as antiquated, especially the one to which it is necessary to add a note that the head is represented erroneously as being thrown backwards. All three, in fact, of this author's figures are very defective, and they have been reproduced several times, both as lithographs and woodcuts, in this country and on the Continent.

The section on the Ulcerative Diseases of the Mucous Membrane, which follows, is more satisfactory. It includes the subject of glanders, and is illustrated by a plate with 5 figures, 4 of which are from specimens in the museums of King's College and St. Thomas's Hospitals. Perhaps the remarks on ozæna might have been extended with advantage. We are glad to observe that Mr. Watson has not passed over in silence those ulcers which sometimes occur with paresis of the fifth pair of nerves, and of which he gives the history of a case which he some time since brought before the Medical Society of London. After ulceration of the mucous membrane naturally follows an account of the same process in bones and cartilages, in connection with which certain affections of the septum are considered. Then we have Diseases and Injuries of the Frontal Sinuses, of the Antrum of Highmore, and of the Lachrymal Sac and Nasal Duct. Plate III. contains 8 figures (7 being from hospital museums) illustrating cysts of the antrum, medullary disease of the naval cavities, and (fig. 7) a polypus hanging from the frontal sinus. The affections of the skin and subcutaneous tissue of the nose occupy the next section, which is carefully done, and includes lupus and rodent ulcers. The subject of this section will, of course, be found treated in all the leading works on diseases of the skin. In lupus, the author thinks that constitutional remedies are very important, and that the destruction of the diseased tissue by caustics should only be employed when the disease is extending. He seems to think well of chloride of zinc, and he mentions the galvano-caustic, a most excellent remedy, but of which he does not express a very decisive opinion of his own. This section is also illustrated by 2 plates, one containing 8 and the other 3 carefully-drawn figures. Then come sections on tumours of the fossæ, naso-pharyngeal polypi, and injuries, mutilations, distortions, &c., with remarks on rhino-plastic operations. All these points are, of course, treated in works on surgery, but Mr. Watson has succeeded in presenting a view of them more complete than can be attained in any such works, and that too within a moderate compass. We next have some very interesting observations on functional derangements of smell, on intra-cranial complications of affections of the nose and its accessory cavities, and last, though not least, on the relations of smell to hygiene and medical jurisprudence. Every reader will be pleased with this part of the work. The appendix contains the history of 80 cases, selected from various sources, including some from the author's own practice. These cases illustrate the several divisions of the work, and form a very valuable supplement to it. Lastly, we are pleased to state that the author has provided a very full index. Perhaps we should add that, besides the plates before-mentioned, this useful work is illustrated with a number of wood engravings.

THE IRISH MEDICAL ASSOCIATION.

The first annual meeting of the Irish Medical Association since its reorganisation was held on Mondey last at the Royal College of Surgeons, and was one of the most succesfful medico-political meetings held of recent years in Ireland. The day's proceedings were opened by a public breakfast at the Shelbourne Hotel, to which Mr. Croly, the Chairman of Council, had invited the members, and which was attended by the leaders of the profession in Dublin, and a large number of the most influential medical men of the provinces. At twelve o'clock the Association reassembled at the College, under the presidency of Dr. Chaplin, of Kildare. The late hour at which the proceedings closed precluding our giving anything in the way of a report in our present issue, we shall devote our next week's Supplement to a full detail of the important proceedings, the report of Council and the speeches of the movers of resolusions. The Association dined together at the Royal College of Surgeons in the evening, under the presidency of Dr. Martin, of Portlaw, the President for the years 1876-7, the Association being honoured by the attendance of several members of the House of Commons and many representatives of the learned professions, and of the public institutions of Ireland.

THE ELECTION OF COUNCIL OF THE IRISH COLLEGE OF SURGEONS.

The customary annual election took place on Monday last, when Dr. Kidd, Obstetric Surgeon to the Coombe Hospital, was promoted from the Vice-Chair to the Presidency, and Dr. Robert M'Donnell was elected Vice-President. As Dr. M'Donnell was not a member of the Council, his promotion did not create any vacancy in the ranks of the outgoing Council, all of whom sought re-election. Therefore the return of Mr. Hamilton, the outgoing president, to the Council, would necessarily extrude one of the nineteen members. Mr. Corley, of the Richmond Hospital, was the only extra-conciliate candidate.

NOTES FROM OUR AMERICAN EXCHANGES.

Rapidity of Filtration.

Dr. Fleetman (*New Remedies*), has called attention to the fact that, contrary to what at first sight might be expected, filtration is much more rapid through thick paper than through thin, and that it is almost twice as rapid through a double filter as it is through a single one, and still more rapid through a triple one. He says that he has taken advantage of this fact for a number of years by employing, in quantitative analysis, a filter of heavy paper beneath the thin one of Swedish paper.

Nitrate of Zinc in the Treatment of Venereal and Other Diseases.

Dr. H. G. Peffard, Surgeon to the Charity Hospital, New York (*New Remedies*), speaks most favourably of the use of nitrate of ziuc as a cauterising agent in the treatment of venereal diseases, pemphigus, &c., and gives a number of illustrative cases in which remarkable success attended its application. The following are examples of its beneficial action:—

1st. Chronic chancroid, one year old ; ten applications ; healed in thirty-one days.

2nd. Recent indurated erosions, diagnosticated chancres of right labium ; one application ; well in four days.

3rd. Recent chancroid, three weeks' duration ; three applications ; healed in eight days, &c., &c.

Veratrum Viride in the Treatment of Pneumonia.

Dr. W. W. Alexander (*Philadelphia Med. and Surgical Reporter*) strongly advocates the use of veratrum viride in the treatment of pneumonia. He pushes its administration "until the pulse falls, the skin softens, and the heat subsides, or other manifest improvement takes place, such as placidity of countenance, easy respiration, and subdued colour, &c." He prescribes six to eight drops, commencing with the minimum dose, every two hours, if necessary, to every four hours, according to the urgency of the case, of a mixture containing equal parts of Norwood's saturated tincture of veratrum viride, and syrup of squills. He suspends the medicine for a few hours if vomiting supervenes, and reduces the dose upon its resumption. He also reduces the dose, or lengthens the intervals, if nausea or perspiration occur during its administration, and discontinues it entirely when all inflammatory symptoms have disappeared.

Dr. Alexander believes veratrum viride to be a most reliable substitute for the lancet in a vast majority of cases of inflammatory pulmonary affections. To quote his own words, "We have treated more cases of pneumonia this season than usual. We have pushed the veratrum in every case. We have not thus far used the lancet in a single case this year, except in one of apoplexy ; nor have we to regret our reliance upon the veratrum, not having lost a case of pneumonia this season. It has been our chief reliance in the treatment of acute inflammatory diseases—our sheet-anchor in pneumonia."

NOTICES TO CORRESPONDENTS.

To Contributors.—Owing to the great length of the proceedings of the Medical Council in our columns during the last two weeks, several valuable contributions, proceedings of societies, and other matter has been unavoidably held over. We crave the indulgence of our friends on this account.

☞ Correspondents requiring a reply in this column are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

Reading Cases.—Cloth board cases, gilt-lettered, containing 26 strings for holding each volume of the Medical Press and Circular, can now be had at either office of this Journal, price 2s. 6d. The postal regulations not allowing the Journal to be stitched, these cases will be found very useful to keep each weekly number intact, clean, and flat, after it has passed through the post.

Vivisection Agitators.—*Apropos* of Lord Carnarvon's Bill for the prevention of cruel experiments on animals, the *Sanitary Record* instances a case which has recently occurred in London, showing the utterly ridiculous positions in which these agitators place themselves. A very popular and amiable clergyman, residing in the neighbourhood of Cavendish Square, has taken into his head that the caterwaulings of the neighbouring cats, which cause him great suffering, are due to the proceedings of some eminent physiologists in his neighbourhood. He has accordingly written to a scientific neighbour, protesting against imaginary vivisections, and urging that even if the interests of humanity require scientific experiment, the rest of Christians ought not to be distracted by the cries of the victims. To cap the joke it should be added that the gentleman to whom he writes has been spending the eason in the country, and has left his house in charge of an extremely unscientific dairymaid, sent up from the farm, who can neither read nor write, and is wholly guiltless of any other "experiment on a living animal" than that of milking a cow.

APPOINTMENTS.

Alsop, T. O. F., M.B., C.M., M.R.C.S.E., a House-Surgeon to the Royal Infirmary. Edinburgh.

Baker, J., L.R.C.S.Ed., a House-Surgeon to the Royal Infirmary, Edinburgh.

Baldwin, E. St. George, M.B., C.M., a House-Physician to the Royal Infirmary, Edinburgh.

Brown, J. W., M.B., C.M., a House-Physician to the Royal Infirmary, Edinburgh.

Browne, D. J., L.R.C.S.I., L.K.Q.C.P.I., Consulting Sanitary Officer to the Londonderry Rural Sanitary Authority.

Cotterill, J. M., M.B., C.M., a House-Physician to the Royal Infirmary, Edinburgh.

Coyne, J., L.R.C.P.Ed., L.R.C.S.I., Medical Officer, &c., for the Crossmaglen Dispensary District of the Castleblayney Union, co. Monaghan.

Forsayeth, J. C. C., L.R.C.S.I., L.K.Q.C.P.I., Medical Officer for No. 4 District of the Saffron Walden Union.

Garson, J. G., M.B., L.R.C.S.Ed., a House-Surgeon to the Royal Infirmary, Edinburgh.

Hetherington, C. E., M.B. T.C.D., Resident Medical Superintendent of the Londonderry District Lunatic Asylum.

Johnson, H. S., L.K.Q.C.P.I., Medical Officer for No. 10 District of the Totnes Union.

Jolly, S. A., L.R.C.P.Ed., L.F.P.S.G., Resident Assistant Medical Officer to the Birmingham Workhouse.

Rigby, W. B., Assistant House-Surgeon to the Wolverhampton and Staffordshire General Hospital.

Service, J., M.B., C.M., Assistant Medical Officer to the City of Glasgow Fever Hospital at Belvidere.

Shoolbred, W. A., M.R.C.S.E., House-Surgeon to the Wolverhampton and Staffordshire General Hospital.

Stone, H. S., M.B., C.M., a House-Surgeon to the Royal Infirmary, Edinburgh.

Tidy, C. M., M.B., C.M., Lecturer on Chemistry at the London Hospital Medical School.

Twining, F. T., M.B., M.R.C.S.E., Assistant Medical Officer at the Homerton Fever Hospital.

Marriage.

Maccall—MacKechnie.—On the 25th ult., at the Congregational Church, West Hartlepool, Dr. Maccall, of Crook, to Emilie Annie, daughter of Dr. MacKechnie.

Deaths.

Davey.—On the 26th of May, at his residence, Hill House, Upper Walmer, Richard Gibbons Davey, M.R.C.S., in his 69th year.

Evans.—On the 24th of May, at Bedwellty House, Cardiff, Edmund Hier Evans, M.R.C.S.E., aged 46.

Eaton.—On the 30th of May, at St. Martin's, Stamford, in the 76th year of his age, William Eaton, M.D., late of Grantham.

Grey.—On April 30, at Kruid Fontein, South Africa, aged 45, George Grey, M.D., late of Newcastle-on-Tyne.

Handsley.—On the 30th of May, at Asford, Lincolnshire, Lucy, the dearly loved wife of T. A. Handsley, M.R.C.S.E.

Hogg.—On the 21st of May, at Dronfield, James Hogg, L.R.C.P.Ed., aged 35.

Home.—On the 16th of May, at Royal Park, Clifton, William Lewis Home, M.D., aged 62.

Hope.—On the 17th of May, at Nuffield Rectory, Henley-on-Thames, John Hope, late of the Bengal Medical Service, aged 69.

Hunter.—On the 20th of May, at Weymouth, John Read Hunter, Surgeon, aged 43.

Lucy.—On the 19th of May, at Westbury, William Lucy, M.R.C.S.E., aged 51.

Moffat.—On the 15th of May, at Blythswood, Glasgow, Thomas Dryden Moffat, L.R.C.P.Ed., aged 40.

Ward.—On the 20th of May, at Kew Green, William Ward, Surgeon, formerly of Bury St. Edmunds, aged 69.

Watts.—On the 19th of May, at Westbourne-park Terrace, Arthur John Watts, L.R.C.P.Ed., aged 40.

IRISH POOR-LAW INTELLIGENCE.

CARRICK-ON-SUIR GUARDIANS.

DISPENSARY MEDICAL OFFICERS AND THE REGISTRATION SYSTEM.

THE following letter was received from the Registrar-General, and read to the board :—

"General Registrar's Office, Dublin,
15th May, 1876.

"GENTLEMEN—I beg to inform you that the office of registrar of births, deaths, and marriages for the district of Piltown is now vacant, owing to the death of Dr. Bowers. It therefore becomes my duty to request you will appoint a registrar for that district within fourteen days, under the powers vested in you by 26th Vic., cap. 11, sec. 23 and 25, and 26th and 27th Vic., cap. 30, sect. 10. I enclose herewith a copy of the general rule declared by me with reference to the qualification of registrars of births, deaths, and marriages, and I beg to add that Dr. O'Meara, the present medical officer, has refused the office.—I am, &c.,

"D. M. BOURKE,
Assistant Registrar-General."

Captain Hamilton expressed an opinion to the effect that Dr. O'Meara could not refuse the office of registrar in his district.

The Chairman concurred with the Poor-law inspector.

Captain Hamilton stated that Dr. O'Meara's appointment to the dispensary was sanctioned on the understanding that he would accept this office.

Mr. Mullins (clerk) believed that in Kilmacow and in Mullinavat the doctors were not acting in the capacity of registrars.

Mr. Morriss knew there were several places in which the doctors were not acting.

After some further discussion, it was unanimously resolved that the question be referred to the Local Government Board for their decision, at the same time expressing the opinion of the guardians that the dispensary doctor was the fittest person to discharge the duties of registrar.

The foregoing discussion is of much interest to Poor-law medical officers. It will be observed that the Registration Office demands the appointment of a Registrar, notifying that the dispensary doctor refuses the office, and leaving the guardians to settle the matter as best they can. The Local Government Board through the mouth of their inspector, declares that the medical officer must accept the registrarship whether he like it or not, and broadly hints that if he refuses to do so, the Local Government Board will cancel his appointment. Now it happens that the Local Government Board have, according to the intentions of Parliament, as expressed in the Registration and Medical Charities Acts, no power to do anything of the sort, though they are armed with such authority as the vagueness of phrasing of the law gives them, to do this or any other arbitrary act, and leave the medical officer to his legal remedy. The attempt on the part of the Local Government Board to force the medical officer to act as registrar is nothing new, for it was confessed in plain terms by Sir Alfred Power, and since then it has been usual—before sanctioning an appointment—to exact a promise from the medical officer that he will accept the office; but this is the first occasion, as far as we know, that an inspector has hinted at dismissal as the penalty of refusal. The Local Government Board has power to dismiss a medical officer by sealed order "on sufficient cause" and it may assume the right to regard a refusal of the registrarship as sufficient cause, but we believe that that assumption would be illegal, and might be successfully contested.

We agree, of course, with the Local Government Board that it is all but absolutely essential that the dispensary medical officer should be also Registrar, and we desire to discourage the refusal of the office by the doctor, so long as the emolument is reasonable. The proper course, however, to take, if it be desired to ensure that both offices shall be held by the same person, is to offer something like a fair payment for the service, so that the Registrarship may be an object of competition, and not an office to be forced upon the medical officer under threats of dismissal. The Local Government Board has adopted such a policy of compulsion lately in more than one instance: they attempted it in the case of vaccination prosecutions, and thought better of it; they have enforced it in the case of sanitary prosecutions. They are preparing to impose new duties in connection with the Food and Drugs Act, and they have now insinuated their determination to compel the acceptance of the office of Registrar. It is time that the profession should prepare for resistance to the indefinite imposition of new and unpaid-for duties.

VACCINATION AND SANITARY PROSECUTIONS.

COUNSELS' OPINIONS.

WE announced recently that the Council of the Irish Medical Association decided to take counsel's opinion for the benefit of the Poor-law medical officers of Ireland upon the question in dispute, whether a vaccinator or a sanitary officer were bound to attend and give evidence at the prosecution of defaulters, and whether they were entitled to fees for doing so. The Council consulted Gerald Fitzgibbon, Q.C., upon the vaccination question, and Robert O'Brien Furlong, Esq., on the sanitary subject.

The cases submitted to counsel are altogether too long for insertion in these columns, but they were drawn by Mr. Wiliamson, the solicitor of the Association, and carefully revised by Dr. Chapman and Dr. Jacob. We give the queries as submitted, and the opinion of counsel upon each.

The Council conceiving that the questions raised before them involved two important and vital principles re-

specting the duties and interests of dispensary medical officer acting as "public vaccinator," namely—

First, as to it being his legal duty as public vaccinator to attend and give evidence in all prosecutions against vaccination defaulters under a compulsory Act, in his dispensary district, without being summoned as a witness for that purpose, on receiving notice from the relieving officer of the district to do so; and—

Secondly, as to whether the attendance on such prosecutions (whether on summons or otherwise) was a duty which should be paid for extra, or formed part of the duties to be performed by such medical officer as such public vaccinator in consideration of the fees payable to him as provided for by the 5th sec. of the 26 and 27 Vic. c. 52 (Vaccination [Ireland] Act), and the Council being desirous to protect the interests and legal privileges of the members of their profession acting in Ireland as such public vaccinators, request to be informed. (*a*)

1st. Is it the legal duty of a dispensary medical officer in his capacity of public vaccinator (appointed as such under the provisions of the several Acts hereinbefore stated, and discharging his duties as such under the general orders, rules, and regulations of the Commissioners for administering the laws for relief of the poor in Ireland [now the Local Government Board of Ireland] of the 29th November 1869, for the government of dispensary districts, &c., and also for the performance of vaccination, &c., also hereinbefore stated and referred to) to attend and give evidence in all prosecutions directed by the guardians of any union against vaccination defaulters, under the provisions of the 13th sec. of the 26 and 27 Vic. c. 52, without first having been duly summoned or subpœnaed by the relieving officer or other officer of the board of guardians instituting such proceedings, upon his receiving notice from such relieving or other officer so prosecuting on behalf of the board of guardians, so to attend and give evidence?

2nd. Is such dispensary medical officer acting as such public vaccinator (whether duly summoned or otherwise for that purpose), on his attending and giving evidence in prosecutions against vaccination defaulters, legally entitled to any additional payment or fees for such attendance, as for his loss of time and expenses incurred in such prosecutions other than the rate of payment or fees provided for by the 5th section of the Act of the 26th and 27th Vic., c. 52, and having regard to the provisions of the 13th section of the said Act, would not the loss of time and expenses incurred by such dispensary medical officer in attending and giving his evidence on such prosecutions be a legitimate source of expense incurred by such board of guardians in connection with such proceedings, and as such should not the board of guardians, upon the production to them by such medical officer of a certificate signed by the justices before whom such proceedings are held, ascertaining the amount of such medical officer's expenses, and certifying that such ought to be allowed and paid out of the poor-rates of the union in which the neglect or default had arisen, pay such sum so certified for by said justices to such medical officer?

3rd. In case of the refusal of a dispensary medical officer acting as such public vaccinator to attend and give evidence on proceedings taken by boards of guardians against vaccination defaulters, under the provisions of the said 13th section of the 26th and 27th Vic., c. 52, unless duly summoned or subpœnaed for that purpose (and without being paid for such attendance, if such dispensary medical officer is legally entitled to such), has the Local Government Board, under the provisions of any of the Acts hereinbefore stated, or of any of its orders, rules, or regulations heretofore made in pursuance of said Acts or otherwise, power to call upon such dispensary medical officer so refusing to resign such his appointments as dispensarary medical officer and public vaccinator, and in case of his (said medical officer) refusing to do so, has the Local Government Board legal power to dismiss him as such by sealed order or otherwise?

[COPY.]

Opinion of GERALD FITZGIBBON Q.C. on Case submitted to him on behalf of the Irish Medical Association as to the legal duty of Dispensary Medical Officer acting as Public Vaccinator to attend and give evidence on prosecutions against Vaccination Defaulters without being summoned &c.

I am quite unable to discover in any of the statutes relating to vaccination or in any of the regulations affecting dispensary medical officers any authority for the assertion that these officers are bound to take part in prosecutions. They are bound to vaccinate and also to take the steps necessary to secure registration and also to supply the certificates which are to be evidence of compliance with the law but these duties with that of reporting to the committee of management are all that I can find to be prescribed and the provisions which make the medical officer's certificates legal evidence for the defence rather tend to show that the personal attendance of the officers at prosecutions was not contemplated by the legislature. I am unable to understand how the absence of the medical officer can be necessarily fatal to a prosecution while it is manifest that his compulsory attendance at petty sessions may be seriously injurious to if not inconsistent with the due performance of his medical and surgical duties. In my opinion the Local Government Board cannot prescribe a duty not imposed by statute and no relieving or other officer either with or without the sanction of the Local Government Board, Board of Guardians or Dispensary Committee can order the medical officer to attend at petty sessions nor would his refusal to attend afford any legal ground for depriving him of his offiice.

If I be right in my view of the law it would be the duty of the guardians and of the Local Government Board in directing prosecutions to provide either for bringing forward sufficient evidence without unduly trespassing upon the time of the medical officers or for fairly remunerating these officers but I am afraid that however clear their rights may be they are not capable in case of resistance of being enforced. The proceedings to compel such vaccination are of a penal character and the medical officers are under the same obligation which rests on every person who may be able to give material evidence to maintain the law of attending when summoned and of giving evidence without fee or reward. The fee for vaccination under 26 and 27 Vic. c. 52, sec. 5 does not include any payment for attending as a witness but in my opinion the medical officer if served with a summons must attend and though the justices might lawfully under sec. 13 of the same Act certify for the payment of any actual expenses incurred in attending I do not think they would be warranted in certi-

(*a*) It appears that the Local Government Board have ruled that in cases of vaccination defaulter prosecutions tried in the town in which the public vaccinator resides, they, the Local Government Board, do not recommend payment by the guardians of any fee to such public vaccinator for attending and giving evidence on such prosecutions; but that if such prosecutions are tried at a court in a town in which such public vaccinator does not reside, and which obliges him to travel a distance, the Local Government Board in such case recommends guardians to pay the public vaccinator for his attending and giving evidence such sum as the justices certify for, but the Local Government Board does not enforce such payment.

fying for a fee for loss of time though probably if they did so indirectly by measuring the expenses liberally the certificate would be valid.

In my opinion the guardians must pay all expenses which the justices shall ascertain and certify to be properly payable unless the certificate show the allowance not to be within the terms of the Act. Every medical officer who attends any prosecution ought to apply for a certificate for his expenses but in my opinion the justices though they ought to grant it cannot be forced to do so.

I have advised that in my opinion the Local Government Board cannot force a medical officer to resign nor can they remove him merely because of his refusal to attend at petty sessions without a summons but besides the extreme difficulty of obtaining the emoluments of his office or of maintaining the position of any individual whom the Board might however illegally attempt to remove it is plain that by instructing the relieving officer to obtain formal summonses the Board might compel the attendance and the medical officer would gain nothing by resistance. The grievance therefore though a substantial and well-founded one can only be aggravated by resistance on the part of any individual or individutls. It must be met by collective action to be taken on behalf of all the medical officers and directed to obtaining from the Local Government Board a regulation which will either preclude the necessity for the medical officer's attendance or will provide for his fair remuneration or to obtaining redress from Parliament.

GERALD FITZGIBBON.

10 Merrion Square, May 22, 1876.

SANITARY PROSECUTIONS.

A question of much importance to medical officers of dispensary districts acting as sanitary officers, namely, Whether it was part of a sanitary officer's duty to attend and give evidence in cases of prosecution under the Sanitary Acts—having been brought by a sanitary officer before the Local Government Board, the following reply was received from such Board :—

Local Government Board, Dublin, 29 Feb. 1876.

SIR,—The Local Government Board for Ireland acknowledge the receipt of your letter of the 24th inst., inquiring whether it is a part of your duty as sanitary officer to attend and give evidence in cases of prosecution under the Sanitary Acts. And in reply, the Board desire me to draw your attention to Part II. (Executive duties) of the General Order of the 9th Sept., 1874, from which you will observe that every sanitary officer is required to attend and assist in all proceedings in which his attendance or assistance may be necessary. With regard to the case which occurred in the Drogheda Union to which you refer, the Local Government Board have to state that their decision in this case had reference solely to the consulting sanitary officer.

By order of the Board,
B. BANKS, Secretary.

It appears from the reply of the Local Government Board, that such Board considers it is part of the duty of the sanitary officer to attend as witness on prosecution, &c. If such is the law, the dispensary medical officers (who are appointed as such under the provisions of the 8th sec. of the 14 and 15 Vic. c. 68, the Medical Charities [Ireland] Act, 1851), and who hold the appointment of sanitary officer of their districts (under the provisions of the 10th sec. of the 37 and 38 Vic. c. 93, the Public Health [Ireland] Act, 1874) consider that they are likely to be regarded by the public as the prosecutor in all proceedings to abate nuisances injurious to health, an impression which is most injurious and adverse to their interests as medical men, including as it does considerable loss of time and other disadvantages in the way of their private practice, particularly so as no payment by way of extra fees or otherwise is provided by the order of the Local Government Board to compensate them for having to attend and give evidence, and otherwise assist in such prosecutions.

Counsel having regard to the 10th sec. of the Public Health (Ireland) Act, 1874, which empowers the Local Government Board to assign to dispensary medical and other sanitary officers their respective duties and functions, within the limits defined in that section, &c., and also having regard to the order of the Local Government Board issued to sanitary authorities in pursuance of said sec. of said Act assigning such duties, &c., will please advise—

1. Is it any part of the legal duties and functions of a sanitary officer (dispensary medical officer) to attend as a witness and give evidence on all sanitary prosecutions instituted in his district, for the purpose of abating nuisances injurious to health and otherwise, without being summoned or subpœnaed for that purpose?

2. Are such medical practitioners, because they are sanitary officers, in such cases entitled to no extra or additional fees, or payment (in addition to the salary or payment made to them as such sanitary officer and as fixed by the Local Government Board) for attending as such witness?

If the 2nd section of the "Executive Duties" of sanitary officers, as set forth in such order of the Local Government Board to sanitary authorities (which directs every sanitary officer and sub-officer of the Union, on receiving directions from the executive sanitary officer, to attend and assist in all proceedings in which his attendance or assistance is required) includes that of attending as a witness on all prosecutions, as referred to in first query, counsel will then please advise—

3. Does the said 10th section of the said Public Health (Ireland) Act, 1874, empower the Local Government Board to assign to dispensary medical officers as part of their duties and functions in the discovery or removal of nuisances, &c., or in generally superintending the execution of sanitary laws within the district, that of attending as witnesses in all prosecutions under the sanitary laws instituted in their district, or is same in excess of the legal powers of the Local Government Board and of the reasonable duties and functions which the said Board have the power to assign and impose upon such dispensary medical officer?

[COPY.]

Opinion of ROBT. O'B. FURLONG, Esq., B.L., on Case submitted to him on behalf of the Medical Association of Ireland as to the legal liabilities of Medical Officers acting as Sanitary Officers of Dispensary Districts and their right to remuneration as such.

By the 10th Sec. of the Public Health (Ireland) Act 1874 (37 & 38 Vic. cap. 93) every Medical Officer of a Dispensary District is constituted a Sanitary Officer for such district or for such part thereof as he shall personally be in charge of with such additional salary as the Local Sanitary Authority may determine with the consent of the Local Government Board for Ireland and the Board are empowered to assign to such Medical Officers their duties in the discovery or inspection or removal of nuisances in the supply of pure water in making and repairing drains and generally in superintending the execution of the sanitary laws within the district.

In pursuance of the power so vested in them the Board issued their sealed order dated September 9, 1874, and thereby assigned to the Sanitary Officer, *i. e.* Dispensary

Medical Officer their duties in which they include that of attending and assisting in all proceedings in which such attendance or assistance may be required when so directed by the Executive Sanitary Officer.

Having regard to the section I have quoted and to the order of the Board I am of opinion that it is part of the legal duties of a Sanitary Officer to attend and give evidence in all sanitary prosecutions arising out of matters occurring within the district of which he is personally in charge on receiving directions to that effect from the Executive Sanitary Officer and without any summons or subpœna.

The Sanitary Officers are not in my opinion entitled to any fee as witnesses inasmuch as the additional salary paid them under the Public Health Act, 1874, was evidently intended to compensate them for the additional duties imposed on them by that Act of which the duty in question is one. I assume that the Local Government Board took this matter into consideration when approving of the salaries determined by the Local Government authorities as it is plain the Legislature intended the remuneration to be "just and reasonable."

As to the second query I am of opinion that the order of the Board of September 9, 1874, is within the powers conferred by the 10th section of the P. H. Act, 1874.

The words "in all proceedings" in Part II. Clause 2 of the Order mean of course in all proceedings relating to the matters specified in the 10th section of the Act. The duty thrown on the Dispensary Medical Officers by the Order of the Board is no doubt an invidious one; at the same time I do not see how it could have been avoided as medical testimony may often be essential to the success of the prosecution.

It seems to me unfortunate that the Legislature have not carried out a suggestion contained in a report of the joint Committee on State Medicine of the British Medical and Social Science Associations, 1872—viz., that, in every county (or for large districts comprising several counties) a Chief Medical Officer of Health should be appointed who should be debarred from private practice who would take the odium and responsibility of carrying out the health statutes without the risk of loss of private practice.

ROBERT O'B. FURLONG.

30 Lower Leeson Street, 23rd May, 1876.

SLEEP.—In offering to your readers my notes and some comments, I shall preface what I have to say by stating my belief as to sleep, or rather my disbelief. Of late years, it, like everything else among the phenomena of health, of disease and of poisonings, has come in for its share of vaso-motor explanation—one man regarding it as a normal congestion, and one as a daily anæmia from vasal contraction. Neither is as yet proven, for although we know that the surface vessels lessen in calibre during sleep, we know but only this, and have no right to the inference so hastily made, that the brain sleeps because of the lessened areas of its vessels. For this is what also happens in the anæsthetic stage of chloroform inhalation—a state most unlike true sleep. I was struck, indeed, about two years ago, with the marked line betwen these states, when as Dr. Wm. Thomson and I were watching the eye-ground of a chloroformed child, through an atropinised and dilated pupil, suddenly I ceased to see the disc with ease; I looked up, and in a moment or two it became clear to us both that the dilated pupil which the chloroform left unchanged, had suddenly contracted, as the child passed into a state of natural sleep, and so stayed until we awakened him, when it opened abruptly—a beautiful illustration of the peculiarities of sleep. Neither in ether nor chloroform poisoning, as all now admit, not yet in sleep, as some are beginning to think, is the vasal state the essential cause of the phenomena. It accompanies sleep, for example, but is not sleep. More probably is sleep a distinct condition of the brain cells—a condition which, perhaps, may never be thoroughly comprehended, and which is more likely in itself a cause than a consequence of contracted vessels.—*Weir Mitchell: Va. Med. Monthly.*

STRONG SOLUTION OF SALICYLIC ACID.—Various solvents for this substance have from time to time been proposed, such as phosphate of soda, phosphate of ammonia, and borax. But none of these yield a very strong solution. The demand for such a solution (aqueous) having arisen, we were compelled to search for another substance—neutral, and itself not irritating—which might take up a large quantity. We finally succeeded by the use of acetate of lime. Proceed as follows:—Introduce 3.1 decigr. (1 oz.) of salicylic acid into a half-pint bottle, add about 12.4 decigr. (4 oz.) of water, and shake well until the salicylic acid has been thoroughly incorporated with the water. Then add 3.1 decil. (1 oz. fl) of glycerin, and finally enough water to make up the bulk to Oss. Immerse the bottle up to the neck in boiling water, and remove it from time to time to agitate the contents. In the course of about fifteen minutes, solution will have taken place, which remains permanent on cooling. In order to prevent water from being spattered into the bottle from the outside, we are in the habit of slipping a perforated rubber nipple over the neck, which allows the vapour from inside to escape, and the orifice of which is too small to allow access of any liquid from without.—*New Remedies.*

PARAFFINS AND THEIR ALCOHOLS.—At the Royal Institution Professor Odling, F.R.S., has been lecturing on this subject. He first referred to the large group of hydrocarbons generally, pointing out that chemists are now acquainted with many hundreds of compounds of hydrogen and carbon, while still there are but two compounds known of hydrogen and oxygen, and two of carbon with oxygen. While most of them readily enter into combination to form further compounds, there is one easily recognisable group that does not, and the members of this group from their slight affinity for combining are called paraffins. The highest and most volatile varieties of the liquid paraffins constitute benzoline, a liquid of many uses in the arts, but exceedingly dangerous for lamps. Some cannon-like explosions were produced by igniting a little benzoline on cotton-wool diffused in a jar of oxygen. The solid paraffins are largely usedin the manufacture of candles. The paraffins are the mosthig ly hydro genised of the hydrocarbons, and hydrocarbons not belonging to the paraffin class become converted into paraffins by their direct or indirect fixation of additional hydrogen. The study of the proportions in which the relative amount of hydrogen and carbon occurs has been of inestimable value in affording a key to the solution of many difficult problems in organic chemistry. In all the paraffins—gaseous, liquid or solid—it has been found that the number of their proportions of hydrogen exceeds by two proportions twice the number of their proportions of carbon. Professor Odling spoke of the isomerism of the paraffins as making known one of the most remarkable phenomena, and offering one the most suggestive problems of modern organic chemistry The study of the conversion of parraffins into alcohols is of great interest, and, as far as is known, there appear to be as many isomeric primary alcohols as there are isomeric paraffins, and the study of these, more than perhaps anything else, helps to increase our knowledge of organic chemistry.

ON THE SCIENTIFIC AND EMPIRICAL INVESTIGATION OF EPILEPSIES.

By J. Hughlings Jackson, M.D., F.R.C.P.,
Physician to the Hospital for the Epileptic and Paralysed, and to the London Hospital.

CHAPTER VIII.—*Recapitulation—The Method Exemplified.*

We have in each case of Epilepsy three lines of investigation: Physiological, which deals with abnormal Function of nerve tissue; Anatomical, which deals with abnormalities of particular Structures (organs); and Pathological, which deals with abnormalities of Nutrition. Or, putting these in their most abstract form and in reverse order, we have to study defects in the Absorption, in the Distribution, and in the Expenditure of nerve-force. The threefold method of investigation will now be exemplified.

1. *Physiology.*—We assume that there is a permanent local "discharging lesion" in every epilepsy. The "discharging lesion" is a permanent instability of grey matter; this unstable grey matter occasionally discharges and the discharge produces effects in, or referred to, the periphery of the body.

2. *Anatomical.*—I try in *each* case where there is a paroxysmal presentation of symptoms, to find the seat of the "discharging lesion" corresponding to them. In any case—let us suppose, however, it is one of convulsion—the question is not "Is it a case of epilepsy?" but "Where is the unstable grey matter which permits the occasional excessive discharge on muscles in this case?" "Of the function of which part of the cerebral hemisphere is the convulsion the brutal development?" Let us put this in another way. If we were present at an autopsy disclosing local gross disease of the cerebral cortex in one who had died subject to convulsions, the question would *not* be "Were the fits which this local disease produced epileptic?" but "What symptoms resulted from the sudden discharge of unstable grey matter near the gross lesion in this case?" If it be replied that the seizures were like those of the "genuine" epilepsy of authorities, we do not consider the reply sufficiently definite, and repeat the question. For Paroxysms of "genuine epilepsy" differ, and therefore the seats of the discharging lesions *must* differ. If it be true that epilepsy is owing to disease of the medulla oblongata, different parts of the medulla must be diseased in cases where the paroxysms differ.

3. *Pathological.*—The question in Pathology is not "What causes Epilepsy?" but "What pathological processes lead to local 'discharging lesions'?" "What is the nature of the abnormal nutritive process by which the cells of grey matter become over-nourished and thus unstable." Inquiries as to the so-called "causes" of epilepsy are wide of the mark if they do not bear directly on this question. I do not mean that empirical inquiries as to what are called "causes" of the supposed entity "genuine epilepsy" are not valuable; but I think they are only valuable as heaps of unassorted material towards determining the real direct pathology of "discharging lesion." Many of these "causes" are simply things determining the first discharge of grey matter already unstable.

It is in accordance with scientific method to study first the simplest problems. No one with any great scientific feeling would study defects of speech before he had studied hemiplegia, or "diseases of the mind" before he had studied the coarser and simpler diseases of the nervous system. Similarly it would be contrary to scientific method to study first the complex, suddenly-occurring, and transitory paroxysms of "genuine" epilepsy before studying those simpler cases of epilepsy which are commonly called "epileptiform seizures."

As we have seen, there are within the limits of my definition of epilepsy all kinds and degrees of phenomena in the paroxysms resulting from "discharging lesions" of

numerous different parts of the brain. Any part of the cerebral cortex may become unstable—either its sensory or its motor region. The motor phenomena, for obvious reasons, are more easily studied. Our illustration must then be an Epilepsy in which convulsion is the chief thing. But there are varieties of these. I have paid most attention to those cases of convulsion which begin deliberately in some part of one side of the body, in the hand for example. These are of all convulsive seizures the simplest; they are far more easily studied than cases of "genuine epilepsy." In many cases of "genuine" epilepsy there is no warning or there is but a vague one; the convulsion is usually universal, nearly equal on the two sides of the body, and the spasm of different parts is more nearly contemporaneous. Moreover the fit comes on suddenly and is rapidly over. On the other hand, convulsions beginning unilaterally are opposite in all these respects and are the very simplest epilepsies we can study: let me state the reasons categorically.

1st. Because since the spasm begins long before the patient loses consciousness and because it sets in slowly, he can tell us much about his seizure. We can thus learn upon what muscular region the first discharge is, if we can learn no more. In some cases of limited convulsion there is neither loss nor defect of consciousness. In the convulsion of "genuine" epilepsy we learn from the patient or from his friends very little more than that there was much struggling, tongue-biting, and other facts which are not of great use in an inquiry like ours.

2nd. Because, since the spasm is often deliberate, we can ourselves when luckily present at a paroxysm note the place of onset and watch the March of the spasm. We learn what parts it affects first and most, how far it spreads, and in what order. In "genuine epilepsy" the spasm is so sudden, so rapidly universal, and so soon over that it is difficult to observe the details of what takes place.

3rd. Because unilateral convulsion not unfrequently leaves a temporary hemiplegia which writes down, so to speak, the parts which in the paroxysm were first and most affected. This of itself is strong, indeed I think conclusive evidence as to the position of the discharging lesion.

4th. Because it has frequently the very definite temporary complication of affection of speech (Aphasia), or of optic neuritis (with or without amaurosis). When there is optic neuritis we can infer so much of the pathology of the case as that the "discharging lesion" is the result of the irritation of coarse disease of some kind ("injury" by coarse disease), or as it is commonly expressed we can say that there is organic disease.

5th. Because since it is the form of epilepsy which depends most frequently on organic disease, we may obtain post-mortem disproof or verification of the diagnosis of locality we made during life. We can from the position of the coarse disease infer the seat of the minute changes of instability which constituted the discharging lesion.

6th. From these cases we learn how arbitrary the distinction is into cases with, and cases without, loss of consciousness, for in convulsions beginning unilaterally there may or may not be affection of consciousness; all depends on the severity of the discharge, on how far it spreads, and on the rapidity of the discharge.

This kind of convulsion I have named variously Unilateral Convulsion, Hemiplegic Epilepsy, Corpus Striatum Epilepsy, and Convulsion beginning Unilaterally. I am not enamoured of any of these terms. Corpus striatum epilepsy seems to me useful as bringing into prominence the analogies betwixt these convulsions and varieties of hemiplegia. "Convulsion beginning unilaterally" is a term not strictly defensible, as the convulsion in the epilepsy of authorities often begins by preponderance of movement on one side. It is, however, the one least open to objection.

The reader is again reminded that I consider the "genuine epilepsy" of authorities to be but one epilepsy in my definition. It differs from Convulsion beginning Unilaterally simply in difference in the seat of the "discharging lesion." In it the grey matter unstable is that of sensori-motor arrangements which are the highest of all—the series of series; in the convulsion beginning unilaterally those of a subordinate series are unstable. This is the reason why, in the former, loss of consciousness is the first or nearly the first thing in the paroxysm, and that in the latter it is a later event. Those who say that the two differ "only in degree" make a remark the truth of which is admitted. In both there are occasional excessive and disorderly expenditures of force on muscles, the discharge depending on instability of nervous tissue. *But in what kind of degree do they differ?* Not merely in degree of more or less spasm—more or less instability of nervous tissue—but also in degree of evolution of the nervous arrangements which are unstable. A convulsion which is universal and in which the muscular regions affected are affected nearly contemporaneously, must depend on excessive discharge of parts in which the nervous arrangements represent a *more intricate* co-ordination of movements in Space and in Time than those parts represent, excessive discharge of which produce a convulsion which begins in one limb and has a deliberate march all over the body. My speculation is that the first kind of convulsion differs from the second in that convolutions at a greater distance from the motor tract—that is nervous centres of a higher degree of evolution—are discharged.

Let me state some of the differences betwixt "genuine" epilepsy and convulsions beginning unilaterally in tabular form. In either case there may be a partial fit, or in other words there may be a slight and limited discharge. Thus there may be only vertigo and confusion of thought in the former, and in the latter numbness of the hand and spasm of the thumb and index finger. But we shall take for comparison cases in which the fits are severe and the convulsions universal.

Genuine Epilepsy of Authorities.	*Unilaterally beginning Convulsion.*
1. No warning or a transient one.	A warning deliberate and local.
2. Consciousness lost very early.	Consciousness lost late.
3. Spasm often universal.	Spasm often limited.
4. Spasm *begins* nearly contemporaneously—on two sides of body, *i.e.*, is nearly universal at once.	Spasm *not* contemporaneous on two sides of body, *i.e.*, *becomes* universal by degrees.
5. Spasm nearly equal on the two sides.	Spasm very unequal on two sides.
6. March of Spasm rapid and quickly over (currents of "great intensity").	March of Spasm deliberate and lengthy. (Currents of great quantity.)

Unless we have well studied the phenomena of discharges of subordinate centres we are not properly prepared for the study of the phenomena resulting from discharge of the highest centres—the centres evolved out of the subordinate centres—that is to say cases of the "genuine epilepsy" of the authorities. (*a*)

From a simple case of the group of unilaterally beginning convulsion I can illustrate the three lines of investigation of an epilepsy. The investigation is to be on the same style as that of a case of paralysis. In the paralysis, as well as in the convulsion, there is a physiological, an anatomical, and a pathological inquiry. We can, indeed, compare and contrast a case of hemispasm with one of

(*a*) Cases of Migraine are the sensory analogues of the Unilaterally beginning Convulsion. The cases of "Genuine Epilepsy" of authorities which begin by "subjective" sensations stand, I suppose, in the same relation to them as the cases of genuine epilepsy which begin by "subjective" movements do to the unilaterally beginning convulsion.

hemiplegia. We speak of the common form of hemiplegia, that so often caused by destruction of the corpus striatum by clot or softening.

Physiology.—In each we begin by determining the physiology of the case, *i. e.*, the functional condition of nerve tissue. In hemiplegia nerve tissue is destroyed, in hemispasm there is clear evidence of instability, for there is every now and then a discharge. In one there is loss of function; in the other there is over function. Thus the first step—the physiological—is easy in each case.

Anatomy.—As the epileptic discharge results in convulsion of the very same parts as are paralysed in the hemiplegia, and as we know that this paralytic symptom is due to destruction of, or of part of, the corpus striatum, I conclude that the discharge is of convolutions in the region of the corpus striatum.

Before we can with confidence point to the particular parts of the convolutional region which is unstable, we must have more autopsies in well-observed cases. Hitzig and Ferrier's work is, however, what will be of most use in these investigations.

Pathology.—The third step is the pathology. Just as in hemiplegia, so in this case; we have to find the pathological process which *leads* to the physiological or functional change. In hemiplegia the question is, "By what pathological process was the *destruction* of the nerve fibres and cells of the corpus striatum produced?" In the epilepsy, "By what pathological process did the instability of the grey matter of the convolutions result?"

In the former case our task is comparatively easy. If the hemiplegic patient be past middle age; if he have Bright's disease, rigid arteries, and hypertrophy of the left ventricle, and if his paralysis came on with deep loss of consciousness, we say the destruction of the corpus striatum is by clot. If he have no Bright's disease, and if the paralysis comes on deliberately, for example in a quarter of an hour, without any loss of consciousness, we say there is local softening from thrombosis of an atheromatous artery. (It is needless to give further illustrations.) In the case of hemispasm our task is far more difficult. We ask, 1st. "Is the local instability the result of a 'coarse' change, such as tumour, or not?" If there be severe pain, vomiting, and double optic neuritis, we say there is 'coarse disease.' We have then to ask, "Is this coarse disease glioma, syphilis, abscess?" The differential diagnosis cannot be entered on here. Let us suppose we can only conclude that there is a coarse change of some kind. In such cases the inference is that the neigbouring grey matter has become unstable by the irritation of the coarse disease. If, however, we find no evidence of the existence of coarse disease we mostly do not trace the pathological process. (*a*) We often do not even at post-mortem examinations. We discover neither local disease of the cerebral hemisphere nor disease of the medulla oblongata. We often discover no local abnormality in any part of the nervous system.

This method, which from long working at seems to me to be simple, will appear just the contrary to those who have worked in a diametrically opposite way. It will seem more simple to first determine by general evidence whether a case be one of "genuine epilepsy" or not,—whether it does or does not conform to some authoritative definition. Next, supposing the diagnosis to be that it *is* a case of "genuine epilepsy," to investigate its causes—the causes of some entity, "the causes of epilepsy." As has been said, the method I have been illustrating cannot be fully carried out in most cases, but it can be carried out as far as the orthodox plan can. The orthodox teaching assumes not only the physiology, but the anatomy. That is to say, it assumes that it is proved not only that epilepsy depends on increased excitability, but also that the part over excitable is the medulla oblongata. As to pathology, the orthodox opinion is certainly in no better case. We all fail in tracing the steps of the abnormal nutritive process by which grey matter anywhere (whether in the medulla or brain) becomes unstable so that it discharges occasionally. When we do discover a gross lesion or local change *post mortem*, we do not even then find out *how* any part of the cerebrum or the medulla oblongata has become unstable as a consequence of that disease. It is, I suppose, the consequence of an inflammation excited by the gross lesion.

(*a*) Inquiry for conditions allowing embolism and thrombosis (including venous thrombosis resulting from aural disease) should be made. (See chap. vi.)

ON THE ORIGIN OF THE DOUBLE-CURVED MIDWIFERY FORCEPS. (*a*)

By Alfred M'Clintock, M.D., F.R.C.S.I.,
Late Master of the Rotundo Hospital.

The question had been started at one of the meetings of the Society by Dr. Kidd as to who it was that gave to the forceps the second or pelvic curve. Now it would be found that nearly all the English and American writers upon the history of the forceps gave the credit of that discovery either to Levret or Smellie. Most of the English and Continental writers claimed for Smellie the merit of the pelvic curve, which was certainly perhaps the most important change in the construction of the forceps that the instrument underwent since its first invention, and one of such importance that more controversy had raged about that curve, with regard to its utility or objectionableness, than with regard to any other point in connection with the forceps or its usé. It was therefore well worth the while of the Society just to spend a few minutes to look back upon this point and to see to whom belonged the credit of this discovery—whether they regarded it as important or unimportant. As Levret had been the one to whom most frequently the credit had been assigned, he (Dr. M'Clintock) would first advert to his claims. Mülder, in his very learned and erudite history of the forceps and vectis, mentioned Levret, his claims and his works. He (Dr. M'Clintock) did not possess the first edition (published in 1747) of Levret's celebrated work on difficult parturition, "On the Cause and Questions of Labourious Labours." He (Dr. M'Clintock) possessed the third edition of that work, and he had the first edition of a sequel to that work published in 1751. He did not believe there was a copy of the original work in Dublin. Various searches he had made had failed to discover that work, but he had ascertained from Mülder's researches what the work contained upon the point. It appeared that in the first published work of Levret, in 1747, that he mentioned there that he had given to the forceps a new curve. Mülder said—"I have seen in Levret's work of the year 1747 it indicated there that he had given to the forceps a new curve, but which he kept secret"—that was to say, he did not describe it in that edition of his work. "That silence was the cause"—Mulder continued—"why certain anonymous writers raised a question concerning the figure and shape of that curve," which clearly showed that Levret did not describe it minutely. The first edition of Smellie's works appeared about the latter end of the year 1751. The date on the title page was 1752, but it was certain that the work must have been given out in 1751, for he (Dr. M'Clintock) had read a review of it published in the *British Register* in October, 1751. The references in Smellie's works to his claims he (Dr. M'Clintock) would presently refer to. In the 32nd collection, case 13—the case occurred in 1752—and in describing that case, which was designated one of pelvic delivery, the child was delivered by the lower extremities, the head being retained in the pelvis. Smellie said that he encountered extreme difficulty in extracting the head, and after pulling at it for a long time, he attempted to extract it with the short straight forceps, but the head was above the brim of the pelvis, and the curve of the os sacrum prevented him from taking proper hold so as to be of proper service, and that was the reason which prompted him to continue a longer kind of forceps, the virtue of which was a curve on one side. That was in the year 1752, and he said in another case—the 34th collection—a similar one, where the head was retained in the pelvis, both arms being delivered, and having failed to extract the child with the short straight forceps (as in the case previously mentioned) he "resolved to try

(*a*) Abstract of a communication made to the Dublin Obstetrical Society, specially reported for the Medical Press and Circular.

the longer pair with the curve on one side to suit the curve of os sacrum." Smellie continued: "They were contrived some years ago by myself as well as other practitioners, all for the purpose of taking a better hold on the head when high up in the pelvis, but I do not recommend their general use, for fear of doing more harm than good when force is used." That was in 1752 that he said that the double-curve forceps were contrived by him and some other paactitioners, but he made no mention of Levret as another inventor of the second curve. He (Dr. M'Clintock) might mention that Smellie was not at all a man in his writings to deprive any one of his just merits and praise, and all through his work he freely acknowledged what everyone that he quoted had done. They would see that in point of time there did not seem to be much difference really between Levret and Smellie, and it was quite possible that each might independently of the other have hit upon the same expedient Now there was another English writer whose work on midwifery was very little known or quoted, and from the study of his book he (Dr. M'Clintock) thought he was one of the most sagacious practitioners of the age in which he lived, a man of great sagacity and great practical skill, but very brief and terse in his descriptions, and making no affectation of knowledge or research. That writer was "Benjamin Pugh, surgeon at Chelmsford, in Essex," whose treatise on Midwifery was published in 1754, and who said in the preface of that work, "I shall be as trite as possible in the description and use of all the instruments both of midwifery and surgery which are my own inventions. So good effects I have experienced many years, and by the help of those in midwifery, that I have succeeded in deliveries without opening one child's head for these fourteen years past. . . . My curved forceps was invented upwards of fourteen years ago (that would be 1740, because the work was published in 1754), and made for me by a man named Archer, a cutler, now living in Chelmsford, and the preference between them and the common straight forceps in every respect is great." So that Pugh was a strong and ardent advocate of the use of the double-curved forceps, and used this forceps in two sizes, just as did their friend Dr. More Madden. Pugh had a long and a short forceps, and the short forceps also had a pelvic curve. One was eleven inches and the other fourteen inches long. In three different places in his work Pugh reiterated the same remark about using these forceps for fourteen years. From these facts he (Dr. M'Clintock) was inclined to think that the merit of the change of construction and shape of the forceps was really due more to Pugh than any one else whose name had been brought forward in connection with it, for about the year 1740, which was seven years before Levret gave any intimation of it whatsoever, he had constructed and was using the instrument. There was a certificate of the Academie Royal of Surgery of Paris, dated the 2nd of January, 1747, which showed that Levret had presented to the Academy a new curved forceps designed with the view of disengaging the head of an infant locked in the passage and arrested by the os pubis, and then it went on to advocate its use, so that that document authentically established Levret's claim up to that year, January, 1747. But then came in, as he (Dr. M'Clintock) believed, the claim of Pugh, but he thought the priority of publication belonged to Levret. Still, however, he thought that if they investigated fairly the history of the matter that Pugh was the man who had the most decided claims to the discovery of this modification of the forceps. In conclusion, Dr. M'Clintock said he thought he had made out a good case for Pugh as deserving the merit of being the original author of the invention.

Clinical Records.

TRANSVERSE FRACTURE OF THE PATELLA UNITED BY BONE. (a)

Under the treatment of Mr. PHILIP BISSEL.

JOSEPH KIRBY, born in Germany, aged 24 years, received a blow upon the patella (right leg) by the slope-car caused by the breaking of the rope, at the Suffolk Colliery on the 17th of November last, which knocked him into the cistern at the foot of the slope. Being at the place at the time I examined it before tumefaction and swelling took place. I found a transverse fracture of the patella, breaking it nearly in the centre. I placed the fractured edges in coaptation, and confined them by taking pasteboard and cutting out a notch in the side, so that when applied it would extend one-half around the patella, the slips extending about six inches above and below the knee on the outer side. Upon the inside I formed a counter splint in the same manner, so that when I had them on there was a hole through the splint for the patella to project. The inside, or between the splint and the leg, I padded with muslin, with a hole to fit. Before I put the splint on I took Mitchell's surgeon's plaster and placed four strips over the patella to hold it together; then laid on my muslin pad with the hole through to fit the patella; placing the same plaster in four long strips over the muslin, to hold it in place; then I took starch and gave the muslin a coat; then, after immersing the pasteboard splints in hot water to make them fit the leg, I applied them to the starched muslin on each side of the patella, covering the femur above and the tibia and fibula below. The splints were wide enough to extend half-way around the leg. Then I applied a starch bandage on top of the splints in such a manner that I should not cover the patella, dressing the leg perfectly straight, but was careful not to put the roller on so tight as to impede circulation. Aside from the fracture he sustained but a few slight cuts and bruises about the head, to which I applied no dressing save cold water. From the exposure of being wet and nearly drowned while in the dump, having swallowed some water, he had a slight attack of congestion of the lungs, from which he recovered without much trouble.

It is now over ten weeks, and to day I removed the dressing, and find perfect union of the bone. I did not remove the splints from the time I placed them there until to-day. I found it not necessary to remove the roller but once, and then only to tighten it after the swelling had subsided. That bony union will take place in all healthy subjects if the bones are kept in apposition is a conceded fact; the late Dr. V. Mott clearly demonstrated that fact, in fracture of the neck of the femur within the capsular ligament, and I have seen him exhibit his specimens to the class in the sessions of 1850 and 1851, and at later periods. I think it is Mr. Paget that says that when there is healthy nutrition and assimilation union will surely take place; if it be bone, then bony union; if muscle, then muscular, &c. All that is necessary is to keep the parts in coaptation, and in some bones where they are not in apposition, the provisional callus not unfrequently takes place, and bony union is the result, as has frequently been shown in the long bones. In course of over thirty years' practice I have had three cases of fracture of the patella; the first recovered with ligamentous union. Since that time I have not failed to obtain bony union in any case when there was healthy nutrition, and in that case I only failed by simply not keeping the fractured ends in apposition. I see no benefit by the use of Malgaigne's hooks or Ahl's splints, as pasteboard immersed in hot water may be adapted to all cases, and as Hamilton has truly said of them, they are a common-sense splint to say the least, and by the aid of starch may be made to suit each individual case.

(a) *Medical and Surgical Reporter.*

Transactions of Societies.

CLINICAL SOCIETY OF LONDON.

MR. GANT had in December, 1872, performed the operation of subcutaneous section of the femur below the small trochanter for anchylosis of the hip-joint, the limb being at a right angle with the trunk. His object in dividing the bone below the lesser trochanter was to get rid of the action of the psoas and iliacus, which if contracted would still retain the limb in a bent position, whereas in Mr. Adams' operation the femur was divided at the neck. After the operation the limb was kept straight by the application of a weight, and primary union taking place, an excellent result was obtained.

Mr. SIDNEY JONES spoke as to the greater safety of the saw than of the chisel as used by Mr. Maunder. He considered Mr. Maunder's operation useful to correct deformity when one limb was affected, but cases occurred in which both limbs were affected, and in such it would be necessary to divide above the insertion of the muscles if any movement were to be obtained. He had, however, in cases upon which he had operated, had difficulty in retaining movement; by passive movement anchylosis had been prevented, but only for a time. In one case in which he had divided the neck of the femur and had used passive motion the union from time to time ossified, and he had continually to break it down whilst the patient was under the influence of an anæsthetic.

Mr. BRYANT had performed Adams' operation in anchylosis of the hip-joint in three cases following strumous diseases, and in one after pyæmia. He obtained a good position in all. It was possible to get movement in division of the neck, but impossible if the shaft of the femur were divided.

Mr. ADAMS had operated in five cases, and had collected the reports of twenty-two other cases, but in none had good movement been obtained.

Mr. MAUNDER, in reply, said he thought the use of the chisel or saw immaterial. He believed that the reason why in some cases anchylosis did not take place was that the head of the bone not being sufficiently nourished, did not become reattached to the shaft. If cut or fractured ends of healthy bone were brought near to each other, nature would certainly unite them. If advisable to prevent bony union it would be necessary to cut away a portion of the bone. He had operated upon his reported cases by means of three chisels successively inserted, but he hoped to have one constructed which would serve the purpose of the three.

A CASE OF INTESTINAL CONCRETION PASSED PER ANUM.

The report of this case by Mr. LEGGATT was read. The patient, a girl, aged three, of fairly good health, after a month of unusual constipation and deficiency of appetite, awoke at two a.m. with vomiting, which continued at intervals for twelve hours. During that time two solid motions, followed by loose stools, passed, and there was some abdominal pain. The temperature in the evening was 102 deg., and the child was drowsy throughout the day. On the next day it was reported that the child had had a restless night, and that motions were passed every hour, accompanied by pain and tenesmus. Temperature 99 deg. The child took notice, but was pale and feeble. The tongue was thickly coated and white. The abdomen was flat, soft, and free from pain. The motions were frequent, and consisted chiefly of mucus, with a little fæculent matter, and here and there a streak of blood. Pulse 120, temperature 100 deg. Milk, lime-water, and rice-water were given as food. On the following day the diarrhœa was arrested for fifteen hours by an enema containing three minims of tinctura opii in starch. Severe abdominal pain, however, supervened during that time, and the temperature increased to 104 deg. The pain ceased on the return of the diarrhœa; and the temperature soon fell to 99 deg. The motions became less frequent, and contained more fæculent matter. The child continued to improve; on the fifth day the concretion was passed *per anum*, without pain; the diarrhœa then subsided; and on the tenth day the child was well. Before the above illness the child had had occasional feverish attacks, with pale, almost white, motions; and since the illness there had been three attacks of vomiting, with white motions, but without fever. Each attack lasted two or three days. For many months before the illness the child had eaten brown bread daily. The concretion had the appearance of similar bodies found not rarely after death in the appendix vermiformis. Analysed by the late Mr. S. W. Moore, at St. George's Hospital, it was found to weigh seven grains and a quarter; its length was three-quarters; breadth three-eighths; and depth one quarter of an inch. In 100 parts it contained 22 of organic matter, and 78 of ash. The 78 parts of ash contained 30 of bone earth, 8.2 of alkaline phosphates, and 39.8 of chlorides, &c. A microscopical examination showed the organic matter to consist of starch granules and wheat husk. A section of the mass presented a laminated appearance. The examination of the concretion, and the fact of the child having been in the habit of eating brown bread, perhaps, afforded an illustration of the mode of formation of these bodies. Other causes besides the concretion, perhaps, produced the illness, such as the habitual constipation of the child, the iron of the Ascot water, &c. But, on the other hand, the concretion might have set up inflammation of the mucous membrane around it, and then possibly the severe vomiting and purging dislodged it. There was not, however, throughout the illness any noticeable pain or tenderness in the region of the cæcum.

Sir WILLIAM JENNER said the concretion was such as he had seen in the vermiform appendix, and he should consider that it had come from that part notwithstanding the absence of all pain. He should not expect pain unless ulceration had taken place, and the inflammatory action had attacked the subperitoneal tissue. When any substance or concretion was contained in the vermiform appendix, its valve-like arrangement would prevent escape, but it might be pressed out during the action of vomiting. He had heard of foreign bodies in the appendix, but had never seen one; concretions he considered not uncommon.

Mr. GANT referred to two cases in which a bean had become impacted in the vermiform appendix, one leading to the formation of an abscess and death, the other to fatal peritonitis.

Dr. BASTIAN had made a post-mortem upon a young man in whom the operculum of a whelk had lodged in the appendix, causing ulceration, from which thrombosis and abscess in the liver resulted.

Dr. DUCKWORTH remarked that fæcal matter is to be found in nearly all appendices vermiformes after death.

Dr. DUFFIN narrated a case in which hair had collected into a mass in the appendix, after causing ulceration, perforation, and death.

Dr. GREENFIELD described a case in which he had found the appendix attached by a meso-appendix, and he thought that its position might have determined the formation of the concretion.

The PRESIDENT believed that concretions would not be likely to form in a normal appendix, and that some bend or abnormal position was usual. In the case of a young lady it was folded up behind the cæcum. Most cases which had come under his notice had occurred in boys.

SUBCUTANEOUS OSTEOTOMY OF FEMUR.

Mr. MAUNDER read a paper of subcutaneous section of bone, and exhibited patients to show how great and important results may be obtained with comparatively little risk. The femur was the bone concerned in all the five cases. Two of these operations had been performed on the same patient, with an interval of some twenty months. This patient, M. A. J., now ten years of age, had been the subject of hip-joint disease, which had left the left thigh fixed by fibrous anchylosis at a right angle to the line of the spine, the head of the femur being wasted and displaced upon the dorsum ilii. Notwithstanding section of contracted muscles and subcutaneous division of the neck of the bone, as suggested by Mr. William Adams, the deformity was in no way lessened, and Mr. W. Adams himself also failed a week subsequently in a similar case. This failure led the author to consider how otherwise to act. The outcome was the operation described, illustrated with such gratifying results. After alluding to Messrs. Broadhurst, L. S. Little, and Gant as pioneers in this department, he pointed out that while a certain number of cases of deformity at the hip-joint were remediable by section of the neck of the femur, a large number of instances of deformity in this region were not suited to that operation, but which could be readily relieved by a division of the femur at a suitable point below the upper end of this bone. Three cases were given, of which that of the child M. A. J. above mentioned is typical. The first operation on her having failed, a second was performed, but *below the lesser trochanter*. *Operation.*—Following the method suggested by Professor Volckmann of Halle, Mr. Maunder uses chisels and a mallet. He employs a double-edged knife for the puncture of the soft parts and lays great stress upon dividing these in such a manner that when the operation is completed the wound in the skin shall not communicate directly with the wound in the bone. He advocates also great care when one instrument is replaced by another, as the knife by a chisel, and one chisel by another, the one instrument being used as a guide to the other. The wound may or may not be closed by a catgut suture, and a compress and strapping are employed. Bony union must be encouraged by rest and a suitable splint. He deems it important also to support the soft parts about the wound in order to prevent oozing into the track of this by the application of a sand-bag after the patient has been returned to bed. Such was the nature of the second operation performed on M. A. J. above alluded to. After both primary union of the soft parts occurred. The child was shown standing erect, and with her lower extremities parallel. An-

other instance was that of a man 21 years of age, who had been the subject of hip-joint disease for seventeen years, and in whom a discharging sinus still existed and does exist. The same operation was performed, and the deformity has been remedied. He can stand erect with both the lower extremities parallel. Possibly the most interesting case, and that showing the great importance of osteotomy, was that of Richard H., aged 30. He was a sailor by occupation, and having broken his left thigh at sea, and being without surgical aid, the fragments had united at an awkward angle, and with complete eversion of the foot. The man stated that the leg was perfectly useless to him as a sailor by reason of this eversion of the foot, and was most anxious to have something done to remedy this condition. Here the *shaft* of the bone was divided; the foot could then be turned to the required position, and was so maintained. The wound healed primarily; the man never had an ache or a pain, or a disturbed night, and in six weeks bony union had occurred. Thus this patient, who at 30 years of age was deprived by the accident of his means of livelihood to which he had been educated, was by the operation restored to usefulness. In contemplating osteotomy in reference to the upper extremity of the femur, the points at which the bone is to be divided must depend upon the altered and relative condition of parts. Mr. William Adams' operation—section of the neck of the thigh-bone—appears to be applicable to cases of anchylosis and deformity in which the head of the bone remains in the acetabulum, both without material loss of substance and also in the absence of much surrounding thickening about its neck. On the other hand, if there be great thickening, requiring an extensive use of the saw so as to leave large surfaces of sawn bone in apposition, this extent of surfaces alone will prevent a restoration of the extremity to the desired position, and small benefit only will result from the operation. Also cases of hip-joint disease, displacement of femur, fixity of its upper extremity by fibrous anchylosis and shortened muscles, and distortion of the limb, are not suited to it, as was proved by the first operation on M. A. J., where the deformity could not be remedied by it. Here it is that section of the bone below the lesser trochanter will make the surgeon quite independent of the fixed upper end of it, and will allow him to place the extremity in any position he may think fit, and insure the greatest prospective benefit to his patient. Thus it will be evident that the large majority of cases of severe deformity resulting from disease of the hip-joint will be best remedied by division of the thigh bone at some point below the lesser trochanter, whilst a minority will still remain best suited to section of the neck of the bone. The author felt justified in saying that the three patients whom he exhibited illustrated the value of the operation described, and the result is that they who were previously burdens upon, can now become useful members of society.

Mr. WILLIAM ADAMS said the members of the society would congratulate Mr. Maunder upon the success of his operation of partially dividing the shaft of the femur below the small trochanter, subcutaneously, by means of the chisel and mallet, and then breaking through the remaining portion so as to allow of the limb being afterwards set in a straight position and firm union obtained. In the three cases exhibited deformity had been overcome, and the limbs were both straight and useful. This operation will be found applicable to a class of cases in which the operation of subcutaneous division of the neck of the femur cannot be performed in consequence of structural alterations from disease in the head and neck of the bone. Another operation in the same situation, and applicable to a similar class of cases as Mr. Maunder's, had previously been performed by Mr. Gant, who used the small subcutaneous saw instead of the chisel and mallet, partially dividing, and then breaking the bone. Mr. Gant has twice performed this operation successfully, no suppuration occurring in either case. Mr. Adams observed that he had also twice divided the shaft of the femur subcutaneously with the small saw for badly united fractures, and once the shaft of the humerus for straight anchylosis of the elbow-joint. In one case no suppuration followed, and but very little in the other. Subcutaneous osteotomy, he observed, has of late received a great stimulus, but bones cannot always be divided with the same degree of safety or freedom from inflammation as tendons, though the great majority of the cases operated upon have proceeded just as favourably as subcutaneous tenotomy. There are now three subcutaneous operations for dividing the neck or shaft of the femur in cases of bony, and sometimes in fibrous anchylosis of the hip-joint, cases which were not previously amenable to treatment, except by operations of such magnitude as those of Rhea Barton, of Philadelphia, and Sayre, of New York:

1st. The operation proposed by Mr. Adams of subcutaneous division of the neck of the thigh bone, applicable to all cases of anchylosis in which there is but little diminution in size, or alteration in shape of the head and neck of the femur. Twenty-four of these operations have been recorded, with only one death from pyæmia, and one eight months after the operation, from chronic suppuration with kidney disease.

2nd. Mr. Gant's operation of dividing the shaft of the bone subcutaneously with a small saw just below the small trochanter, applicable to cases in which the neck of the femur could not be divided, in consequence of the structural alterations from disease; and

3rd. Mr. Maunder's operation in the same situation as Mr. Gant's, and applicable to similar cases, but performed by means of the chisel and mallet.

Mr. Adams' experience led him to prefer Mr. Gant's operation where the neck of the femur cannot be divided, and believed that the small subcutaneous saw will be found a more manageable instrument than the chisel and mallet.

In reply to a question by Mr. Sydney Jones, Mr. Adams stated that he had not succeeded in retaining motion in any of the five cases in which he had divided the neck of the femur, but Mr. Jessop, of Leeds, Mr. Lund, of Manchester, and Dr. Sands, of New York, had all succeeded in retaining motion.

DUBLIN OBSTETRICAL SOCIETY.

THE Society met on April 11th, 1876, Dr. LOMBE ATTHILL, President, in the chair.

The PRESIDENT exhibited a specimen of comparative rarity, namely,

EXOMPHALOS IN A FŒTUS

at about the sixth month of pregnancy. The child was born in the Rotunda Lying-in Hospital a few days prior to the meeting. The labour was unattended by any difficulty, and they could easily imagine that the case was one simply of a diseased fœtus. The mass which he exhibited was one of those cases of congenital exomphalos, the whole of the intestines, and in this case the liver, being protruded through the umbilicus, and forming a external tumour of considerable size, as compared with the fœtus itself. The envelope of the mass was composed of the integument of the umbilical cord, and as was common in these cases, the vessels of the cord appeared to be divided; but they generally found the umbilical vein running posteriorly and working at each side. On opening the sac they found the large mass, which consisted of the liver (very much enlarged), the stomach (small and rudimentary), and the intestines large and small below it, in fact, it appeared to him that the whole abdominal contents lay outside the abdomen, with the exception of some very small portions. Cases had occasionally occurred in which the whole contents of the abdomen were so extruded in children, and possibly in adults, but the distinguishing mark being congenital, the envelope was pellucid. On account of the small size of the fœtus, and the size of the mass, labour was easy, but cases sometimes occurred in which these tumours were so large as to offer serious impediments to the birth of the child and seriously embarrassed the surgeon. He thought it worth while to bring the specimen before the Society, as the occurrence which it illustrated were not a very frequent one. In the Obstetrical Society of London, a case of exomphalos had he thought been brought forward which had occurred in an adult. The specimen he now exhibited was the first of the kind that he had seen for many years.

Dr. MORE MADDEN, Vice-President (who had taken the chair during the President's communication), said these cases were so very rare that he was afraid the members of the Society would not be able to add very many to the one just recorded by the President.

Dr. BYRNE said he had a specimen of the kind in his museum, but the tumour was much larger. The child was born alive, and the fœtus was very large, and an acephalous one. It appeared to him to be a question whether this was the cause of the death of the fœtus or not. It was a very interesting pathological inquiry whether the tumour protruding caused any kind of gangrenous affection. He believed they

had not much information to throw light on this very interesting condition.

Dr. M'CLINTOCK then made a communication to the Society (quoting a number of authorities) as to

THE ORIGIN OF THE DOUBLE-CURVED FORCEPS,

which will be found at page 481.

In the succeeding discussion,

The PRESIDENT said the communication that Dr. M'Clintock had made to the Society was a very interesting one. It was not always the man who deserved most credit for an invention that received it. He thought the Society was under great obligations to Dr. M'Clintock.

Dr. KIDD said he was very glad that a chance remark of his had drawn forth this communication from Dr. M'Clintock. He (Dr. Kidd) was very much under the impression that Levret was the author of the pelvic curve. He confessed he never looked very closely into the matter. He had on more occasions than one tried to make it out, but had not taken the pains that Dr. M'Clintock had, and he (Dr. Kidd) had come to the conclusion that Levret was the author of it, and he thought it lay between him and Smellie, and what led him to attribute it to Levret was that he believed Levret's book was published more than four years before Smellie's was. However, there could be no question now from the statements and facts laid before the Society by Dr. M'Clintock that Pugh was really the author of this new curve for the forceps, and there were scarcely any of their books in which the matter had been clearly stated. He did not think that Pugh's claims were ever put forward before. He (Dr. Kidd) thought it was a matter of great literary importance that the fact should be so clearly proved to them that Pugh really was the author.

Dr. M'CLINTOCK observed that the ablest *résumé* of the history of midwifery he had ever seen was that of Caspar Siebold. It was really a most wonderful book. Siebold gave a digest of the writings of every author of any note on midwifery for nearly four hundred years. His (Dr. M'Clintock's) attention had been drawn to the book some year or two ago. In that learned and most accurate work, generally speaking, almost the entire credit of the pelvic curve was given by Siebold to Levret. He gave no credit to and made no mention of Benjamin Pugh.

Dr. T. MORE MADDEN thought the Society must owe a debt of gratitude to Dr. M'Clintock for having brought before the Society such interesting information as that which had been afforded in his communication. The subject which Dr. M'Clintock had brought before them was one that at the present day was constantly engaging their attention, as to the comparative advantages of the two instruments. As for the history of the forceps, so it was with the history of many of our modern discoveries — they had been anticipated by ancient writers. It was interesting to trace back the history of the intrument. In the works of many of the old writers there were a great number of instruments which had been brought out as new instruments, and a great many which had not been were noticed. He thought there was great advantage in drawing attention to the works of the old writers, whether they were of an antiquarian or scientific character, and more especially with regard to the subject that had been discussed, as it was one by which the members of the Society might hope to profit.

Dr. KIDD said that the case which he desired to bring under the notice of the Society was one of ovarian disease—

MULTILOCULAR TUMOUR, COMPLICATED WITH PREGNANCY, RUPTURE OF THE CYST, AND PERITONITIS,

which will be published in our next.

On the motion of Dr. Denham, the debate on the communication was adjourned until the next meeting of the Society.

DR. BALTHAZAR FOSTER has been elected President of the Birmingham Medical Benevolent Society for the ensuing year.

IN the discussion by the Council of the Royal College of Surgeons of England on Lord Carnarvon's Vivisection Bill on Thursday last, a general opinion was expressed that legislation is unnecessary, and subversive of the interests of science.

THE GENERAL COUNCIL OF MEDICAL EDUCATION AND REGISTRATION.

IN our last we gave the business of the Session up to nearly the close of Saturday's (June 3rd) sitting, when the additional words proposed by Sir Dominic Corrigan in the report of the committee on the Registration of certificates in Midwifery. The remainder of Saturday was occupied with the further discussion of the same report.

REGISTRATION OF CERTIFICATES IN MIDWIFERY.

Dr. Thomson moved the adoption of Section 5 of the committee's report, which was agreed to.

"The committee are of opinion that the communication on the subject of State medicine qualifications from the British Medical Association should be acknowledged; and that the Association should be informed that the subject of a qualification in State medicine or public health has long occupied the attention of the Council. The committee would recommend the Council to express their opinion that any degree or diploma in State medicine should not of itself (that is to say, apart from any of the present qualifications) constitute a claim to be enrolled in the Medical Register. Whether the diploma, though not separately registerable, might properly be admitted to registration on the footing of an additional qualification is a question which, in the opinion of the Council, does not at the present time admit of being brought to a satisfactory settlement."

The following additions to the foregoing paragraph was also agreed to:—"Whether the diploma, though not separately registerable, might properly be admitted to registration on the footing of an additional qualification is a question which, in the opinion of the Council, does not at the present time admit of being brought to a satisfactory practical settlement."

On the motion of Dr. Thomson, seconded by Dr. Pyle, the following words were substituted for clauses 3 and 4 of section 2:—"As regards the registration under the Medical Act af a diploma in State medicine, as proposed by Mr. Gibson's Bill, the committee recommend that the Council should express their opinion that any degree or diploma in State medicine or public health, which may be granted by any of the bodies mentioned in Schedule A to the Medical Act, should not of itself (that is to say, apart from any of the present qualifications) constitute a claim to be enrolled in the Medical Register."

Dr. Smith complained that the report, as amended, did not express, with sufficient clearness, the view of the Council that the privilege of registration should not be limited to universities; and he proposed the addition of the following words:—"The committee are further of opinion that, if such qualifications be rendered registerable by Act of Parliament, the privilege of such registration should not be confined to universities as provided in the Bill, but should also be extended to all degrees, diplomas, and certificates in State medicine or public health which may be granted by any of the bodies included in Schedule A of the Medical Act."

The report thus amended was agreed to. It was also resolved that the report, so far as it related to the Bill of Mr. Gibson, Mr. Russell Gurney, and Mr. Cowper-Temple, should be transmitted to the Lord President of the Privy Council, and that copies of the resolutions of the Council in answer to their communications be addressed to the Royal College of Surgeons of England, the Obstetrical Society of London, the British Medical Association, and to the Secretary of the Foreign Graduates Association.

The Council then adjourned.

WHIT-MONDAY, JUNE 5TH.

With commendable anxiety to finish the business of the session, the Council met two hours earlier than usual, notwithstanding that a general holiday was observed in the metropolis.

After the usual preliminaries the Council proceeded to discuss the Report of the Committee on—

PRELIMINARY EXAMINATIONS.

Dr. Haldane moved the following resolution :—"That it be recommended to the various licensing bodies to instruct their examiners in professional subjects to report to them any cases of decided ignorance in general education displayed by candidates, with the name of the board or boards before which the preliminary examinations have been passed ; and that the licensing bodies be requested to transmit such reports to the registrar of the General Medical Council." He said on the importance of preliminary examination no doubt could be entertained. He felt that the only way to raise the social position of members of the medical profession was to raise the standard of education. The efforts of the Council in this respect had been fully appreciated by the medical profession and also by the public ; but although good had been done the benefits derived had not been quite in proportion to the good will of the Council. Having acted for several years as an examiner both in preliminary and professional examinations he had arrived at these conclusions, viz.,—That of the candidates who present themselves for preliminary examination a considerable proportion were decidedly deficient in regard to general education ; and secondly, that a considerable number of students were admitted upon the Register whose attainments in general education did not justify such admission. With reference to the first point, he spoke as having been on the board of preliminary examiners a number of years. In Edinburgh the standard for the preliminary examination was the minimum fixed by the Council ; for obligatory subjects there were English, Arithmetic, Algebra, Geometry, and Latin, the optional subjects, of which the candidate was to take one, being Greek, French, German, and Natural Philosophy. This certainly was not too high a standard, but it was a melancholy fact that a very small portion of the candidates were able to pass this examination on the first occasion. The knowledge of English could only be said to be moderately satisfactory, and a certain number of candidates were rejected every year for deficiency in spelling. In Latin the deficiency was positively deplorable, not more than twenty or twenty-five per cent. passing on the first occasion. Two of the optional subjects—viz., Greek and German—were very seldom chosen, but the students selecting them generally passed. In French and natural philosophy the result was different, as he noticed that students often had a sort of smattering on these subjects. These results clearly showed that the knowledge of candidates was very deficient, and pointed to a comparatively low state of the preliminary education of the country. How it happened that candidates were admitted upon the Register who had such very deficient preliminary knowledge he did not propose to explain. He did not believe it was from any wish on the part of the different bodies to evade the directions of the Council, but rather from a sort of desperation. The candidates who appeared were often so bad that the examiners felt, if they rejected every man who ought to be rejected, comparatively few would be allowed to study for the medical profession. Be this as it may, there could be no doubt of the fact to which he alluded. The remedy was in the elevation of the general education of the country, but with that the Council could not interfere. The only other plan was to introduce the system of visitations that had proved so successful in the case of professional examinations ; not that he proposed that the Council should send visitors to the different preliminary examinations, but that the differing licensing bodies should, so to speak, visit one another. The object of his resolution was to recommend that in cases where candidates for professional examination displayed decided ignorance in general education, examiners should be requested to report on the matter to the bodies with which they were connected, and that those bodies should be recommended to transmit to the Council either the reports in question or a statement of the facts.

Dr. Haldane's resolution was seconded by Dr. Storrar.

Dr. Pitman expresed an opposite view : he said that if any exceptions were to be taken to the knowledge of candidates who came up for ther professional examinations they should be taken at the time they were passing, and not afterwards. If this resolution were sent to the licensing bodies they would have great difficulty in dealing with it, and he doubted very much whether the Council would get any useful information on which they could act. He believed some better plan might be devised if more time were given for consideration. The Council ought to be very careful in putting before the licensing bodies any recommendation which they could not conscientiously enforce, and he did not think they could do so with the one now before them.

Dr. Wood was surprised at the objection taken by Dr. Pitman. There was a number of men who, when they came up for their professional examination, showed the grossest ignorance in general education, and the embarrassment caused to professional examiners was very great ; and no doubt men were admitted into the profession who were totally incompetent. He conceived Dr. Haldane's object to be that when men were found so deficient in their general education, find out where they passed their preliminary examination, and call the attention of those bodies to the fact in order that their examinations might be improved. The Council were quite entitled to take action upon this question, because it was part of their duty to prepare a list of the bodies who had to qualify in general education, and if they found any board was sending inefficient men into the profession they would take care to erase them from the list. He thought therefore they should try the effect of this recommendation.

Sir. D. Corrigan entertained very serious objections to Dr. Haldane's resolution, which he believed would be wholly impracticable. He agreed with Dr. Pitman that if there was an objection to be made to preliminary examination it ought to be made at the time of such examination. He believed it was possible for a man to have a profound knowledge of medicine and surgery who has no very great knowledge of Latin and Greek. He proposed the following amendment :—"That the only true guard against decided ignorance in general education displayed by candidates will be found in the laying down of a curriculum, specifying that examinations were to be held at certain specified times in like manner as adopted by universities in their course of arts, and that failure at any one of these examinations shall incapacitate candidates from proceeding to the next examination until the previous examination in which failure occured has been passed."

Dr. A Smith in seconding the amendment, remarked that Dr. Haldane's object was of the highest importance, but he thought the time had not arrived for setting it in operation. In the present state of affairs it would be exceedingly difficult to find out where the preliminary examinations of candidates had taken place. But, presuming it had been found out, say at Montreal or Melbourne, how could they get any control over those bodies ? The motion involved the reconsideration of the whole question of preliminary examinations, and he believed one of the first duties of the Council at its next meeting would be to take up seriously the question of preliminary education. It would be wiser to postpone the subject to a future meeting than to pass a crude resolution that would be really of no use in the meantime.

Dr. Haldane consented to withdraw his resolution and would substitute for it the following statement :—"The General Council desire to direct attention to the important fact that many candidates still enter upon their professional studies who are very deficient in preliminary education."

Sir Wm. Gull said he would second the substituted motion. It was no doubt of the greatest importance, if the medical profession was to retain its position in society, it should see that the gentlemen entering it be intelligent and well instructed. He placed intelligence first, because a medical man should have intelligence and that must be tested by his education. Medicine being an intellectual profession, the intelligence of the students should be tested as far as possible as well as their education, and so tested as to exclude men obviously unfit for such a profession, but who would make very useful members of society in some other calling. No doubt the preliminary examinations were the stuff of which medical men were to be made, and unless the material was good at the beginning it was in vain to work upon it afterwards.

The substituted amendment of Dr. Haldane was agreed to; his first proposition being withdrawn by consent and Sir Dominic's resolution negatived.

THE REPORT OF THE COMMITTEE ON VISITATIONS

was then presented.

Dr. Humphry, as chairman of committee, brought up this report, and moved that it be received and entered on the Minutes. In doing so, he said he could not refrain from expressing the sense of the committee at the irreparable loss they, indeed the whole medical profession, had suffered in the decease of their late chairman, Dr. Parkes. Speaking of the visitations he said they were commenced by the Council in no censorious spirit, but with a simple desire to ascertain the facts relative to the examinations of the United Kingdom, and of assisting the various licensing bodies to correct one another. The spirit in which those visitations were commenced had been well responded to by the several bodies; and the tone which had characterised both the reports of the visitors and the remarks of the licensing bodies upon them, with very few exceptions, had been eminently satisfactory to the Council and creditable to all concerned. This being so, the committee felt it would be wiser not to press any fresh resolutions or recommendations on the Council at the present time, but to leave these visitations to work their own quiet way and to exercise their influence by their own weight. The committee did not wish that the Council should hold itself responsible for the analysis made or the opinions expressed, but rather that they should remain on record for the consideration of the bodies who would undoubtedly use them, and for the guidance of future visitors, and perhaps for the future action of the Council. In stating that the result was on the whole satisfactory, he merely meant that the Council might rest satisfied that a sufficient test was given in the various subjects required, not that the examinations were entirely satisfactory. Every one must feel that examination and education were so associated with one another that examination could scarcely be said to be satisfactory till education was satisfactory too.

Dr. Rolleston seconded the resolution.

Dr. A. Smith said grave charges had been made against him and Mr. Power with regard to their report of their visit to the examinations of the Royal College of Surgeons, Ireland. The whole charge rested on a garbled quotation of a sentence in a part of the report, and would never have arisen if the Council of the College of Surgeons had not misrepresented the report.

Mr. Macnamara claimed the right to reply on behalf of the College of Surgeons.

The President said it was not usual to allow replies to personal explanations.

Mr. Macnamara asked the President whether it was to be tolerated that any member of the Council should be permitted to throw dirt against any of the bodies represented at this board, and its representative not be permitted to reply? Whether false statements might be allowed to go forth to the public through pages of the press, and the parties aggrieved not allowed to contradict them? Whether individuals should be aspersed, and no opportunity afforded for their vindication?

The President ruled that no discussion could take place upon Dr. Smith's explanation.

Mr. Macnamara then opposed the report being received because it contained inaccurate statements.

Sir D. Corrigan also objected to the report being entered upon the Minutes, as nine-tenths of the public would regard it as an adoption of the report by the Council. The report was unfair towards the Queen's University, and he recommended that such an unholy production should be passed over in silence.

Upon being put to the vote, the motion of Dr. Humphry was agreed to.

Prof. Turner moved "That the Report of the Committee on Visitations of Examinations of June 25th, 1875, and the Report of the Committee of Visitations of June 5th, 1876, be considered on the first day of session of 1877."

Mr. Teale seconded the motion, which was agreed to.

On the motion of Dr. Humphry, the following report of committee on

THE TABLE OF RESULTS,

which was as follows, was adopted:—"The Committee appointed on May 25th to consider the table showing results of professional examinations for degrees, diplomas, and licences granted in 1875 by the bodies in Schedule A of the Medical Act, with reference to so large a number of rejections, report — that in order to arrive at any conclusions on the causes of the rejection of so large a number of candidates in the examinations, it will be necessary to obtain information and opinions from licensing bodies on the subject. The committee therefore suggest that the Executive Committee be empowered to do this, and that it should report at the next meeting of the Council. The committee recommend that information be obtained from the licensing bodies on the following points among others:—1. As to the chief causes which led to the rejection of candidates in the professional examinations for a licence to practise. 2. Whether it is desirable that any alterations should be made in the subjects of the examinations, or in the number of the subjects, or in the range of any of the subjects, and what those alterations should be. 3. As to the education of the candidates who present themselves for examination. 4. As to the subject or subjects on which rejections are most frequent, and as to the causes to which the rejections in these subjects are especially to be attributed.

PHARMACOPŒIA COMMITTEE.

Dr. Smith moved that the following report be received and entered on the minutes:—

"The Pharmacopœia Committee have to report that 4,020 copies of the last reprint of the Pharmacopœia have been disposed of since its publication, and that 10,754 copies of the additions have also been sold. The whole outlay and return are exhibited in the table of expenditure and receipts, together with a statement of the stock in hand. It must be gratifying to the Council to observe that 29,000 copies of the Pharmacopœia which they have published have been sold in less than ten years, and that the sale continues without diminution, proving the value of the work and the estimation in which it is held. With reference to the future, the committee think it right to direct attention to the fact that the stock of the Pharmacopœia on hand amounts to only some 900 copies, and that as the present average sale of the work exceeds 1000 copies annually, it will be necessary to provide for a fresh issue of the work within the next twelve months. The committee, therefore, recommend that the Council should authorise the Executive Committee to take the necessary steps at the proper time for a reissue of 5000 copies of the Pharmacopœia of 1867, with the additions. The committee recommend that the Pharmacopœia Committee be reappointed."

The report was agreed to, and the following gentlemen

were appointed as members of the committee :—Dr. Quain, Dr. Pitman, Dr. Haldane, Dr. Smith, and Mr. Macnamara.

Professor Rolleston then proposed—"That the committee be entrusted with the preparation of such corrections as may be fairly considered as editorial ; and that, with the concurrence of the Executive Committee, they be empowered to make such further corrections as may seem to them to be urgently desired."

Mr. Turner seconded this resolution, which was carried.

RESIGNATION OF THE REGISTRAR.

Dr. Stokes said the resolution he had to propose involved a grateful though painful duty, and as such he believed it would be frankly accepted by every member of the Council. It was—"That the General Medical Council, whilst accepting Dr. Hawkins' resignation of the Registrarship, desire to express their deep sense of the courtesy and ability with which he has for eighteen years discharged his duties to the Council. The Council beg Dr. Hawkins to accept this resolution as a sincere acknowledgment of the great value of his services."

Sir Wm. Gull seconded the resolution, which was carried by acclamation.

Dr. Hawkins said he was entirely taken by surprise. He thought he had received more than his share of kindness already. He thanked the Council, and should ever remain grateful.

VACCINATION.

Dr. Storrar said in the course of the current year a letter came under the notice of the Executive Committee and of the Branch Council for England from a Mr. Gidley Moore, a medical practitioner in London, who complained that, although he had received a qualification from the Colleges of Physicians and Surgeons, he had been objected to as a candidate for a parochial appointment because he had not received proper instruction in vaccination. Mr. Moore complained to the College of Physicians, and his complaint was forwarded to the President of the Medical Council, who entered into communication with the President of the Local Government Board. Dr. Storrar remarked that somehow or other all the examining bodies in England, with the exception of one, had entirely overlooked the two resolutions come to by the Medical Council in the year 1868, viz :—"1. That a certificate should be required by each licensing body from every candidate for its degrees, diploma, or licence to practise medicine or surgery ; that he has studied vaccination under a competent and recognised teacher ; that he has himself performed the operation successfully under the teacher's inspection ; that he is familiar with the different stages of the vaccine vesicle, and with the method of preserving lymph, and is thoroughly informed in every necessary part of the subject. 2. That such a certificate should only be received by any licensing body from recognised vaccine departments in medical schools or hospitals, or other public institutions where the appointed teacher of vaccination is not liable to frequent change, and where ample means for study are provided by not less than such a number of cases (perhaps eight or ten on an average weekly) as may be found, after due inquiry in the first instance, confirmed by authentic returns, or inspections from time to time, to be sufficient for this purpose at each place." He believed the College of Physicians of London had now taken steps to put itself in comformity with those recommendations, and the only course he thought advisable was to refresh the memories of the licensing bodies on the subject. He moved—"That the attention of the General Medical Council having been drawn to the subject of Certificates of Proficiency in Vaccination, and particularly to the correspondence between the President of the Council and the President of the Local Government Board on the case of Mr. J. Gedley Moore, of Ongar (*see* Minutes Exec. Committee, 27th March, 1876) by which it appears that the recommendations of the Council as regards Certificates of proficiency in vaccination have not been complied with by all the licensing bodies, and that registered practitioners are liable to disabilities in consequence of such non-compliance, the Council invite the special attention of all the licensing bodies to these recommendations, and request that such as have not yet put their regulations in accordonce with them will lose no time in doing so."

Dr. Pitman seconded the motion. He said it was not quite accurate to say that the College of Physicians had "overlooked" the recommendations of the Council, for it was in consequence of the recommendations of the Council that the College issued a new certificate of vaccination which they supposed was in strict accordance therewith. The error arose upon the construction of the word "recognised," and it was thought that by recognising such teachers as were appointed at the several hospitals and public schools, they would be carrying out the recommendations of the Council. Results had shown that this was not the case, and that it must be some one who was an appointed teacher by the Local Government Board, which difficulty would not arise in future, because, as the Secretary of the Local Government Board said, "The Board directs me to add that since the receipt of your letter they have been in informal communication with the Royal College of Physicians, and that they learn that the authorities of the College are about to propose to the College such a modification of their present practice respecting the evidence of proficiency in vaccination to be required of candidates for their licence as will give full effect to the recommendation of the Medical Council, and satisfy the requirements of the Local Government Board."

On the motion of Dr. Storrar, it was resolved to send a copy of the resolution to the licensing bodies.

UNQUALIFIED MEDICAL PRACTITIONERS.

The following communication from members of the Council of the Medical Defence Association was read :—

12, Colebrooke Row, Islington, May 29th, 1876.

"Sir,—I am directed by the members of the Council of the Medical Defence Association to forward the memorial sent herewith, and to say they trust you will be pleased to bring the same before the notice of the General Medical Council during the present session.—I have the honour to be Sir, your obedient servant,

(Signed) "GEORGE BROWN.

"Hon. Sec. Medical Defence Association.

"To H. W. Acland, Esq., M.D., F.R.S.,
President of the General Medical Council.

To the President and Members of the General Council of Medical Registration and Education.

"We, the undersigned, on behalf of the Council and Members of the Medical Defence Association, all of whom are registered medical practitioners, desire to urge upon your notice the pressing necessity for an immediate alteration in the Medical Acts, in order to check more effectually the practice of medicine and surgery by ignorant and unqualified persons. At present no means exists which can be made use of to prevent the assumption of medical titles by unqualified persons. The Medical Act of 1858, from which the public and the profession expected so much, is practically inoperative in this respect. It is found that in order to secure conviction under the 40th section thereof, the prosecution must prove that the person complained of wilfully and falsely pretended' to be *registered* under the Act. Many unqualified practitioners, especially those who hold foreign and 'bogus' diplomas, evade this section by stating in their public announcements that they are 'unregistered.' Others state they were unaware that they were infringing the Act, and escape on this plea. Others again open a shop or surgery, designating it a 'Medical Hall" or 'Provident Dispensary.' The proprietors of these places do not announce their names, or personally assume any medical title, so that it is found impossible to obtain their conviction under the present Act. The Council of the Medical Defence Association, having gained much experience in the working of the Act, respectfully suggests that a short Bill should be introduced into Parliament, to amend the Medical Act of 1858, by substituting for the 40th section thereof the following :—"Any person whose name is not

on the *Medical Register* who shall take or use the name of a Physician, Doctor of Medicine, Licentiate in Medicine and Surgery, Bachelor of Medicine, Master of Surgery, Surgeon, General Practitioner, or Apothecary, or any name, title or addition implying that he is qualified to practise medicine or surgery, shall upon a summary conviction for any such offence, pay a sum not exceeding twenty pounds.' The Council of the Medical Defence Association earnestly beg your powerful support in effecting the amendment above suggested, or such modification of it as may seem to you calculated to carry out the object set forth in this memorial.

"Signed on behalf of the Medical Defence Association,
"Benj. Ward Richardson, M.D., F.R.S., President.
"Alfred Meadows, M.D., F.R.C.P., Vice-President.
"W. Spencer Watson, F.R.C.S., M.B., Treasurer.
"George Brown, M.R.C.S., Hon. Secretary.

The Council resolved to acknowledge the memorial, and to inform the memorialists that at any time when the Council might have under consideration the question of a general amendment of the Medical Act, the subject to which the memorial referred should have careful consideration.

The President read a communication from the Royal College of Physicians of London, stating that they had lately resolved that three months' clinical attendance at an asylum for insane persons might be accepted in lieu of three months' clinical attendance at a general hospital. They had also made the change with respect to the requirement in vaccination before referred to.

On the motion of Dr. Wood, seconded by Mr. Teale, the report of the Recommendations Committee was received and entered on the minutes, but its consideration was deferred till next session.

Dr. Smith moved, "That the cordial thanks of this Council are eminently due, and are hereby tendered to Dr. Andrew Wood, for his services as Chairman of the Business Committee during the present session of the Council."

Sir Dominic Corrigan seconded the resolution, which was carried by acclamation.

The thanks of the Council were also voted to the treasurer, Dr. Quain, and to the chairmen of the various committees.

On the motion of Sir William Gull, a cordial vote of thanks was heartily accorded to Dr. Acland for his efficient services as President of the Medical Council, which was suitably acknowledged, and the business of the session was brought to a close.

One of the female patients died on Friday last from the bursting of the water-tank in St. George's Hospital.

The Home Secretary, in reply to a deputation which waited upon him on Friday last relative to the duties of coroners, said the subject required much consideration, which would be given to it by the Government as soon as time permitted.

In consequence of the suspicions entertained as to the sudden death of the late Sultan of Turkey, telegrams have been forwarded with a view to confirm the statement that he committed suicide in a moment of desperation by opening the arteries in both arms with a pair of scissors.

The death of Deputy Surgeon-General Sandford McVittie Lloyd at Halifax, Nova Scotia, on the 8th of May, is announced. He was admitted M.R.C.S. Eng. in 1839, and obtained the degree of M.D. Glasg. in 1847. He entered the army as assistant surgeon in 1841, and was promoted to surgeon in 1848, surgeon-major in 1862, and deputy surgeon-general in 1870.

WEDNESDAY, JUNE 14, 1876.

THE GENERAL MEDICAL COUNCIL.

The General Council of Medical Education has this year deliberated for a period of eleven days, at a cost of £1,880, abstracted from the profession. Their time has been devoted almost entirely to the consideration of Parliamentary Bills, and though doubtless Parliamentary Bills may have much to do with professional interests, yet we unhesitatingly express the opinion that matters of national importance that require to be settled or investigated by professional men should be paid for by the nation, and not by the profession. It is right that there should be a Medical Parliament, and that every medical man should assist in supporting it, and if in some years there appears but little interest in return for the investment, it is a sufficient satisfaction that some of the deliberations of this Parliament have produced results of incalculable value. During the late, and, we may add, important meeting of the Council, national subjects have been discussed, to the almost complete exclusion of matters which closely concern the well-being of the profession.

Lord Carnarvon's Bill covers a subject with which the profession, as a whole, are absolutely unconcerned. Of the students who study medicine in London, ninety-nine per cent. never see an experiment performed upon a living animal, and when they enter into practice, their whole time is devoted to the special duties and toils of practice, and experimentation upon living animals never suggests itself to them. The few individuals whom the Bill concerns are men of scientific pursuits who spend their whole life in the cause of science, and in return obtain but little more than a paltry pittance, for in no country are men of science so ill-paid as in England.

The public have become impressed with the idea that every student of medicine and every *doctor* delights in torturing dogs and cats, and we are told by a minister that, in his opinion, the majority of the members of the House of Commons will only be satisfied by passing a Bill which shall prohibit all experimentation upon living animals. The Medical Council have ably discussed the

merits of the question, and have put forward in plain arguments the results which would follow the passing of such a Bill. It was the duty of the Government to ascertain by a commission the facts, and nothing short of gross ignorance or prejudice could fail to recognise what effects the passing of the Bill would have; but the Government have shielded themselves behind the Council at an expense to the profession of little less than £500.

As regards the decision of the Council it may be remarked that we have in former articles urged that legislation upon the practice of vivisection is by no means imperative, as some ignorant or blindly prejudiced persons have led the public to suppose, but that, on the contrary, it has up to the present time scarcely gained a footing in this country. It would have been perhaps better had the Council, instead of suggesting alterations in the Bill, at once declared that the practice of vivisection, as carried out in this country, did not justify legislation. It is useless to attempt to hoodwink the public; neither the Bill nor its suggested alterations will bring about what certain sections of the public desire. On the other hand, no law, civil or religious, can in these times stand against science and its advancement, and no law will prevent vivisection, any more than it could prevent human dissection. There was a time when the public would not tolerate dissection of the human body—it was inhuman—it was irreligious. But dissection was a road to knowledge, and fortunately there were those who disregarded public opinion; there were those who would learn from the dead how to save the living, regardless of any punishment that might be inflicted upon them. What was the result? a law was actually enacted to protect *dissectors*, and to supply them with material for dissection. And now comes the same public outcry against vivisection: prohibit cruelty to animals; vivisection is called cruelty, and therefore must be prohibited. But vivisection, like human dissection, is a road to knowledge, bearing upon human suffering, and fortunately there are those in the present day who, with a knowledge of right, and acting conscientiously, will still disregard a perverse public opinion, and will work for the good of the public in spite of themselves; and if any law be enacted, it will surely result ultimately in protection to vivisectionists rather than in prohibition of vivisection.

The public are unable to take an abstract view of the subject of vivisection, but they may realise it where it touches the individual. One point particularly referred to in this Bill is the performance of operations upon living animals for the purpose of obtaining manual dexterity. It is extremely rare for such a thing to happen, because in very few operations can any manual dexterity be gained by operating upon the lower animals. But arguing from this point, we conclude that every surgeon must perform each operation for the first time once in his life, and that there are many operations which, if not performed with manual dexterity, are followed by disastrous results to the patient. Is there a man living who, if about to undergo the operation, would not say—"By all means let the surgeon gain experience on a dog, or a hundred dogs, before putting my sight, or perhaps my life, in jeopardy." Such being the case, every person who signs a memorial against vivisection employed with judgment, either is ignorant of what he is signing, or selfishly trusts that others, and not he, will be the objects of the early, or, so to speak, experimental operations of young surgeons. We repeat that the subject of vivisection is one touching the public, and not the medical profession, except as a part of the public. Whatever may become law, not one medical man in five thousand will reap any advantage or suffer any disadvantage except as an individual member of the public; but payments which have been taken from members of the medical profession, at a time when they can ill afford it, have been, and probably will continue to be, unless the *Press* calls attention to the fact, devoted to State purposes which ought to be defrayed out of the national Exchequer.

THE LAST QUARTERLY RETURN OF THE REGISTRAR-GENERAL.

Some months back we drew attention to the interesting and instructive nature of these returns, and showed how, under cover of a vast array of figures and of dry statistical details, there was to be found a good deal of useful information. It is not our intention to enter into the subject so fully as we did then, but in order to keep our readers *au courant* with the general state of the health and with the general prosperity of the English public, we may select a few of the more interesting facts contained in the last return.

The *marriage* returns are as usual in arrears, and are for the last quarter of the year 1875, while the return of births and deaths is for the first quarter of the present year. It is gratifying to notice that the marriages exceeded the average, and increased faster than the population. At the same time *pauperism* is still diminishing. The number of in-door paupers was one per cent. less than in the corresponding three months of 1875, while the decline of paupers receiving out-door relief was equal to ten per cent. We need scarcely remark that these facts are a good sign of the increasing prosperity of the nation, particularly when we take into consideration the high price of meat and other articles of food. The great discrepancy between the marriage rate of agricultural and that of manufacturing districts is shown in this as in previous returns. For whilst the marriage rate in the last quarter of 1875 was but 15·1 per 1,000 in the agricultural counties of the south-western division, it was 21·7 in the Yorkshire division. And not only is the marriage rate in agricultural counties low, but it is declining.

The return of *births* is remarkably large. In the first quarter of this year the births of 229,980 children were registered, a number exceeding that recorded in England and Wales in any preceding quarter, and equal to a rate of 38·0 per 1,000 of the estimated population. The registration of births was made compulsory in England by the Act which came into operation on 1st Jan., 1875, but the Registrar-General thinks it improbable that the recent large increase in the birth-rate is entirely due to this cause. The birth-rate was lowest—31·4 and 32·4—in the principally agricultural populations of the south-western and south-eastern, and highest—42·2 and 44·0—in the mining and manufacturing populations of the north-western and northern divisions.

We come now to the *deaths*. During the first quarter of this year the number of deaths registered was equal to an annual rate of 23·5 per 1,000 of the estimated population. This death-rate was 1·1 below the average rate in the corresponding quarters of the ten years 1866-75, which is rather remarkable considering the extraordinary alternations of temperature which obtained during the first three months of the year. One of the most noticeable features in the present return is the excessive death-rate in Lancashire, indicating the unsatisfactory sanitary condition of that county. In comparing the health and population of Lancashire with those of London the Registrar-General makes the following remarks: "The estimated population of the county is 3,072,689, the average density being 2·4 persons per acre. The estimated population of London is 3,489,428, showing an average density of 46·3 persons per acre. Bearing in mind the definite relation between density of population and mortality, the death-rate in Lancashire should be considerably less than that in London. The facts show very different results. The annual death-rate in London in the first quarter of 1876 was 24·7 per 1,000, whereas it was so high as 29·8 in Lancashire. Without taking into account the disadvantage which London suffers from having a population more than twenty-two times as dense as that of Lancashire, it is evident that if the death-rate in the quarter in this northern county had not exceeded that which prevailed in London, nearly 4,000 persons would have survived, whose deaths were recorded in Lancashire, and were due in great measure to the unsatisfactory sanitary condition of its urban population."

One fact which never fails to be wanting, or to startle the reader in these reports, is the great mortality among infants under one year of age. We fear this will be the case for a long time to come, and perhaps it is one of the laws of nature that, however much man may strive to the contrary, a large percentage of the human race should not survive the age of infancy. The 142,269 deaths at all ages included 33,516 of infants under one year of age, equal to 146 per 1,000 of the births registered, showing, however, a decline of six per 1,000 from the average proportion in the six preceding corresponding quarters. When reviewing the last quarterly return, we fully noticed the excessive infantile mortality in the manufacturing districts, and the causes thereof, and the present return only echoes the facts to which we then drew attention. We may, however, note the great infant mortality which prevailed in the city of Carlisle, where the deaths of infants under one year of age, partly o wing to the fatality of whooping-cough, were in the proportion of 282 per 1,000 births. Not less remarkable is the decline of infantile mortality in Leicester. "The proportion in the borough was 130 per 1,000, or 24 below the average in the twenty largest towns, and no less than 54 per 1,000 below the average proportion in the borough during the corresponding quarter of the three years 1873-4-5. The special inquiry into the cause of the high rate of infant mortality in Leicester, recently conducted and reported upon by Messrs. W. E. Buck and G. C. Franklin, would appear to have already exercised an effect upon the existing evil, although the sanitary defects arising from the complete saturation of the subsoil (attributed to the river being dammed up against the town by mills) and the imperfect sewage outfalls have probably not yet been remedied."

Turning now to the causes of death, we are glad to see that the death-rate from zymotic diseases showed a further decline from that which prevailed in the two preceding corresponding quarters, and was 0.7 below the average zymotic rate in the first quarters of the six years 1870—5. Scarlet fever, although less fatal than in either of the last two quarters of 1875, again caused in the first quarter of 1876 more deaths in England and Wales than any other of the principal zymotic diseases. Of the smaller towns or villages in which this fever was especially fatal, we may mention Freemantle, where, says the local registrar, "there is no drainage, and the water is impure;" and Chard, the epidemic of which is also attributed to "the bad sanitary condition of the town." On the other hand, the present return shows a further considerable decline in the deaths referred to fever in general, including typhus and typhoid fevers. "There appears to be no sufficient reason," observes the Registrar-General, "why this continuous and considerable decrease in the mortality from fever should not be accepted as satisfactory evidence of an average improvement in the sanitary condition of the English population, especially in towns." But there is plenty of evidence to show that this sanitary improvement is unequal, and is in many localities still much needed. In those towns where sanitary reform is steadily progressing, the fever rate is low, whereas it is high in those places where sanitary measures have been neglected. For instance, the recent epidemic of fever in Sheffield "is as instructive as it was disastrous." A considerable part of the town was drained many years ago into the river Porter, since which the river has been so polluted with various kinds of refuse and liquid impurities, that its bed has been raised to the extent of about five feet, thus burying the outfalls of many of the sewers. This raising of the river bed undoubtedly contributed to the heavy floods which in October, 1875, deluged the cellars and basements of a large number of houses in that town with sewage; while it is to be noted that a severe outbreak of enteric fever followed shortly upon the floods, and "caused during the six months ending March, 1876, more than 200 deaths, and probably more than 1,000 other cases terminating, after protracted suffering, in recovery."

There are some families who look upon *measles* as rather a trivial complaint, who never think of resorting to medical assistance when their children are attacked with that disease, and are contented to do nothing on such occasions, but give them a little syrup of saffron, or some equally simple medicine. We, however, know that measles is by no means free from danger, and therefore we are not surprised to learn that an outbreak of this disease caused 114 deaths in Blackburn, where an excessive mortality from fever and other zymotic diseases also occurred. The death-rate in this town from the seven principal zymotic diseases was universally high. Blackburn is a town of about 80,000 inhabitants, and the Town Council has, remarks the Registrar-General, fixed the salary of their medical officer of health at £25 per annum!

There was a great increase in the deaths from *small-*

pox in and around Manchester and Salford; but had it not been for this local epidemic, the deaths from small-pox in England and Wales in the first quarter of this year would have been fewer than in any quarter since the commencement of civil registration.

Notes on Current Topics.

Illegal Practice Defence Association.

A NUMBER of unqualified practitioners who have formed themselves into a society under the name of the "British Medical Reform Association," held a conference at Hull a few days ago, of which an account is given by the *Students' Journal and Hospital Gazette*, under the presidency of a Mr. Woodhead, of Liverpool. Among the subjects discussed at the conference was that of the acceptation by registrars of deaths of death certificates issued by members of the association, and the general opinion expressed by the speaker was, that such certificates could not be legally refused, an opinion which certainly shows that the speakers knew nothing of the subject. Some discussion took place on the question of titles. It was proposed that in all official documents the members of the "Reformed" School of Medicine should use the title of "Dr."; but as the legality of this course was questioned, the subject dropped without any formal resolution being adopted. The irregular practitioners which form this association may be congratulated on having been permitted to pursue their practices unmolested by the law during the past twelve months, but they will act wisely in not presuming too much on the freedom of action they have been permitted to enjoy.

Poisoning by Santonin.

PROFESSOR BINZ communicated to the Medical Society of the Lower Rhine, Bonn, the case of a child two years old, that was attacked with fits after taking two chocolate lozenges, each of the strength of 0.05 gramme santonin, or about one grain and two-thirds in all. The spasms came on in ten hours, and endangering respiration. The seat of irritation was evidently within the sphere of the nerves of the third up to the seventh pair. The pupils were dilated. The urine showed the usual greenish colour. By means of the warm bath, vinegar enemas, abundant drink and artificial respiration, the patient recovered, the spasmodic attacks becoming weaker and less frequent by degrees. The want of a reliable antidote caused Binz to make a number of experiments, and ultimately he found that chloral hydrate effectually prevented the appearance of convulsions. Inhalation of chloroform also proved effectual, and inhalation of ether suppressed convulsive attacks altogether when administered at the first twitching of eyelids and ears, and curtailed the spasms in duration and violence when resorted to after their appearance. A full dose of santonin given to an animal under the influence of ether, and to another not so narcotised, killed the latter within three or four hours, whilst the former recovered perfectly in a few days. Artificial respiration by means of tracheotomy and the bellows diminished the attacks, but did not entirely subdue them. Binz recommends in all cases of santonin poisoning, in addition to the antidote indicated, the employment of purgatives and plenty of drink for the elimination of the drug.

The Ventnor Consumption Hospital.

IT was a happy idea of Dr. Hassall's when he started a fund for the erection of a hospital for consumption in the congenial clime of the Isle of Wight. Happy, however, as was its conception, the founder, in his most sanguine moments, could hardly have dreamed of the warmth of the public response. But six years have elapsed since the first appeal was made, and now a magnificent structure, consisting of sixteen separate buildings on the cottage principle, with a church in the centre, the whole furnished and complete, is the result. One bar, however, exists to the perfect harmony of the whole, for the removal of which the chairman, Lord Selbourne, made an earnest appeal at a banquet in London on Saturday last; out of sixteen houses, the doors of two of them remain closed for want of funds, owing principally to the increased cost of maintenance. We are happy to say that the handsome sum of £2,000 was contributed in the room, but this need deter no one disposed to add thereto. Mr. Frederick Coleman, the treasurer, has a capacious iron safe, and will, we are sure, be very glad to find room and to take care of any additional contributions sent for the National Hospital for Consumption, Ventnor.

Frozen Fresh Meat from Australia.

A CORRESPONDENT of the *Times* says the growth of meat in Australia is so much greater than the requirements of the population that the pastoral tenants have, according to seasons and circumstances, either had to "boil down" the surplus or else "tin" and export it as "preserved meat." However good in quality, or however carefully prepared, experience has proved that there is a great prejudice against it in the mother country, especially among the very classes for which from its cheapness it was expected to be best adapted. Mr. T. S. Mort has come to the front, and, after eight years of unwearied efforts and repeated disappointment, has at last succeeded, at a cost to himself solely, of over £100,000, in perfecting appliances by which whole cargoes can be shipped frozen, and kept frozen while on the passage, so that on arrival in England the whole uncooked fresh carcass can be handed to the meat salesman as sweet as when first killed. Meat kept at the works for months has been tested by hundreds of people who could detect no difference in flavour or appearance between it and ordinary butchers' meat.

Longevity.

As many as 20 of the 28,290 persons whose deaths were registered in Ireland in the first quarter of the present year are described as centenarians. There are three among them registered as 106 years old, one 109, one woman 110, and two men 111 years of age. The local registrars do not vouch for the truth of the statements of age. The Registrar of Dungiven, Londonderry, however, after recording the death of a person returned as aged 102 years, adds:—"Which, from minute inquiries, is believed to be accurate." The Registrar of Tallow, Lismore, returning one of the deaths at the age of 111, says:—"This man was married in 1798, the year of the Rebel-

lion, and was then 33 years old." The other death at 111 is recorded at Castleblayney, and the Registrar says —"The informant said he could give proof that the deceased was born in 1765, and it seems death took him by surprise in 1876, as he fully expected to reach his father's age, which was said to have been 115." If these two men were 111, more than 90 of their years were passed under only two Sovereigns.

Railways and the Cattle Disease.

THE North-Eastern Railway Company have been charged with contravening the provisions of the Contagious Diseases (Animals) Act and the subsequent Orders in Council with respect to the conveyance of cattle; and as foot-and-mouth disease, pleuro-pneumonia, and the scab all exist in the district, the case excited some interest. The specific charge against the company was that they did neglect to clean and disinfect two loading pens before 12 o'clock at noon on the 25th of April. The Orders in Council provide that loading pens shall not be used before being thoroughly cleansed and disinfected in a certain manner after cattle had been in them, and Captain Tennant, the Government Inspector, had found two of the company's pens inefficiently cleaned on the above day. The Treasury did not wish to press the case unduly, and Mr. Brown, for the company, admitted that they were "in part guilty," the officials, through a great pressure of business on the day in question, having only cleansed the bottoms, and not the posts and rails of the pen. The penalty incurred was £20, but a fine of £2 and costs, £5 4s. 7d., only was inflicted.

Mice Plague on the Border.

THE Border sheep farms are suffering from an irruption of mice. A similar visitation occurred in the New Forest and Forest of Dean in 1813 and 1814, when the mice, besides devouring the grass, did immense damage to the trees, especially to hollies. On that occasion the most effectual means of destroying them appears to have been by pitfalls, in which they were caught by thousands. It is said that the vermin are annoying and injuring the Dandie Dinmonts of Tweedside. The mice are supposed to have come from some distance; for the short-tailed field mouse or vole is comparatively rare in the south of Scotland, its place being taken by the long-tailed species —a true mouse (*Mus sylvaticus*).

Painful Points in Neuralgia.

MORE than a score of years ago, M. Valleix, the distinguished author of the "Guide du Medicin Practicien," called attention to the frequency of vertebral *points douloureux* in neuralgia, and the necessity of directing the treatment to them. Prof. Duplouy, of Bordeaux, now publishes the particulars of three cases of neuralgia that resisted all other treatment, and eventually rapidly subsided after the application of blisters to these points.

Powder for Producing Ozone.

IN order to produce artificial ozone, Mr. Lender makes use of equal parts of peroxide of manganese, permanganate of potash, and oxalic acid. When this mixture is placed in contact with water, ozone is quickly generated. For a room of medium size two spoonfuls of this powder, placed on a dish and occasionally diluted with water, would be sufficient. The ozone developes itself; it disinfects the surrounding air without producing cough.

The Brussels Hygienic Exhibition.

THIS exhibition promises to be a great success. All the European nations are taking part in it, and consignments are expected from the United States, Canada, &c. The opening ceremony takes place on the 26th inst. by the King of the Belgians, the arrangements for which are now being rapidly proceeded with. Up to the present time the English and German departments are the most advanced, and although the works contributed by English exhibitors are unaided by Government assistance, there is every reason to believe that England will be very well represented. The chief department, which is set apart for English exhibitors, is admirably adapted for exhibition purposes, and measures 1,140 feet in length, and 135 feet in width, having a total area of about 2,000 yards. There will be an official reception given by the burgomaster and municipal authorities to the exhibitors at the Hotel de Ville, on the 24th inst., and the Count of Flanders will subsequently introduce some of the leading visitors to his Majesty. A very splendid room is being fitted up inside the building for the reception of Royal and distinguished visitors, and a buffet will also be provided for the accomodation of general visitors.

Lord Carnarvon's Vivisection Bill.

THIS Bill is creating an unusual sensation among large sections of the profession, and at a *soirée* given by the Medico-Chirugical Society, on Tuesday week, nearly all present, including the President of the Society, Sir James Paget; Dr. Risdon Bennett, President of the Royal College of Physicians; Dr. Quain, F.R.S., Dr. Wilks, F.R.S., Dr. Hilton, F.R.S., Professor Marshall, F.R.S., Professor Mivart, F.R.S., Dr. Cobbold, F.R.S., Dr. Sibson, F.R.S., Mr. Spencer Wells, Dr. Marcet, F.R.S., Dr. Robert Barnes, Dr. A. W. Barclay, of St. George's; Dr. Chadwick, of Leeds; Dr. Waters, of Chester; Mr. F. Jordan, of Birmingham; Dr. Radcliffe, Dr. A. P. Stewart, and many others, signed a petition to the House of Lords. The petitioners said that they "are of opinion that the Bill entitled 'The Cruelty to Animals Act, 1876,' will, if passed into law in its present shape, seriously impede the progress of research into the laws and functions of life in health and disease, will retard the advance of medicine, will prevent the complete and satisfactory instruction of students in important branches of knowledge necessary for their future efficiency as medical practitioners, and will thus be injurious to the cause of humanity." They, therefore, earnestly prayed their Lordships to give favourable consideration to the amendments of the Bill proposed by the Parliamentary Bills Committees of the British Medical Association in a report, dated May, 1876, and to a like report of the General Medical Council of Great Britain of the like date, and especially prayed that if their Lordships passed the Bill they would make therein amendments which would have the effect- "1st, of amending the title of the Bill in such manner that it shall not seem to impute to physiologists and to teachers

in medical schools a disposition to cruelty; 2nd, of widening the limits of research by experiment, so as to include, as heretofore, all subjects of research which can conduce to new knowledge of facts or laws of life, or additions to medical and physiological knowledge; 3rd, of permitting the practice of experiments of research in non-registered places by licensed persons or under special certificate; 4th, of omitting the limitation which the Bill imposes on the animals which may be subjects of experiment, and removing the exemption of cats and dogs which clause 5 proposes, seeing that the domestic flesh-eating animals are most necessary for many subjects of important inquiry." The petitioners said that "in making these earnest requests they are animated by the sentiments of humanity which are prevalent throughout the nation, and which are especially dear to them whose profession it is to pass their lives in the prevention and cure of suffering and disease. Intimately acquainted with the nature and object of the studies which the Bill proposes to regulate, your petitioners earnestly trust that you will amend, as they now pray, the provisions of this Bill, which threatens to arrest, if not to destroy, in this country, the pursuit and diffusion of a kind of knowledge most necessary for widening and strengthening the bases of medicine, and for multiplying and improving the means by which the laws of life may be more fully learnt, the beginning of disease more readily checked, the action of remedies more clearly perceived, and the art of healing rendered more certain and more beneficent."

Dr. Wilks, writing to a contemporary, designates "the principle of the Bill as odious, and clauses ridiculous."

The Public Health (Ireland) Bill,

Which was introduced by the Chief Secretary ten days ago, and is looked for with much anxiety by the sanitary medical officers of Ireland, has not yet been printed or laid on the table of the House, and we are therefore not in a position to inform our readers as to its nature. It is set down for a second reading for Monday next, but we trust will not be taken on that evening, inasmuch as it would be very unreasonable that the House of Commons should be expected to adopt the principle of so important a measure with less than a week for its consideration.

The interests of nearly 1,500 medical men in Ireland are deeply involved in it, and for this reason—if for none other—ample opportunity for its consideration should be afforded. We understand that the Bill will be as nearly as possible a copy of the English Public Health Amendment Bill of the year before last. A notice has been placed upon the paper by Mr. Biggar, M.P., that he will move its rejection; but as a similar notice from the same honourable gentleman is appended to nearly every Irish Bill, the opposition, we imagine, is not seriously meant.

Five Children at a Birth.

QUINTETTS are fortunately not common productions in this country; let us charitably hope that the following announcement which appears in the last number of the *Melbourne Medical Record* has often to be made, even for Java:—"At the Sugar Factory, Wonoriddio, near Pasoeroean, at the east end of Java, the wife of a native coachman, named Slokoo, has presented her husband with five children—three sons and two daugeters—at a birth. One of the female children has ten fingers on each hand—five being of full size, and five barely half size."

The announcement is painfully brief; we trust the poor woman's delivery was equally so; albeit we should like to be furnished with a few medical notes of the case, and to learn how many of this interesting brood survived their entrance into this nether world.

A Vegetable Curiosity.

A MARROW has been exposed in a shop window since September last. On opening the marrow it was found that the seeds had germinated inside. The young plants are healthy, with sprouting rootlets, and have a slight green colour. They have developed into second leaf, and the network of green vigorous young plants is especially striking. The marrow is to be seen at the present time at a seedsman's in High Holborn.

Cookery among the Poor.

THE Sisters belonging to St. Alban's Mission are giving practical lessons to some of the girls. Two or three of the sisters appear to be good cooks. The things cooked are purchased at the places usually patronised by the poor, many articles being equal to, but not one half the price of those sold at the West End shops. Soups are not very popular among the poor; they are unable to make them palatable, and they have the idea that the solids are the nourishing foods. A soup at once palatable, nourishing, and inexpensive may be prepared with milk, onions, and potatoes. The scraps and cuttings of meat from butchers' shops, which can be purchased at one-fifth the price of joints, when simmered in soup, are as valuable for the development of tissue in the human frame as the most expensive joints themselves; whereas, in the frying-pan the same scraps are rendered tough, hard, and indigestible, a large quantity being converted into animal carbon by the application of too great heat. It would be true charity to teach the poor the application of those few points of science which may be said to daily act and react upon their very existence.

Hospital Sunday.

SUNDAY, the 18th inst., is the day appointed for the annual appeal for our hospitals. The Lord Mayor and Sheriffs will proceed in state to attend the morning service at Westminster Abbey, and the afternoon service at St. Paul's. This being the first Sunday after Trinity, the Judges will meet the Lord Mayor, and according to ancient custom, proceed with him in state to the afternoon service. This cannot fail to give unusual *éclat* to the service in the Cathedral.

Decrease in the Number of Medical Practitioners in Great Britain.

IN his inaugural address to the Medical Council, the President referred to some statistics supplied to him by Dr. Farr, and contained in the thirty-fifth Report of the Registrar-General. In the army there is a surgeon to every 202 men; in the general population 1 to every 1,276 of the proportion. The population of medical men n 185 1 was 9·7 to every 10,000 living, 8·3 in 1861, and

only 7·8 in 1871. In the army 49 per 10,000 are required. It has become a matter of public concern, that it is difficult to supply the vacancies in the army medical staff with competent practitioners. Dr. Farr further writes to me, "One thing is certain, that the medical attendance for the people of England was extremely defective in 1851, and that it is still more defective iu 1876. The danger is, that it may grow quite inaccessible to vast numbers of the people. We know how this arises. Every one in the profession wishes to see every man in it instructed up to the highest standard." It appears from Dr. Burke that in Ireland the proportion of medical men seems to have increased from about 4 to each 10,000 in 1851, to 5 per 10,000 in 1861, and 6 per 10,000 in 1871. But Mr. Pitt Dundas states that in Scotland the number has diminished, as in England. There were 7·2 per 10,000 in 1851, 6·1 per 10,000 in 1861, and 5·2 per 10,000 in 1861. Should it appear, says the President, on investigation, that the supply of medical men is inadequate, and that the poorer classes especially are attended by unregistered practitioners, it may become a proper subject of inquiry by the Council whether there is any ground for supposing the examinations to be undesirably deterrent, for the methods of preparing for them in any special manner inadequate, or whether there are any details of study enforced which have no direct relation with the clinical practice of their profession, and of which the average student's memory may be lightened; or whether the secondary schools which our students attend do indeed give the best preparation for the medical life, whatever that may be.

National Health.

THERE is a society in London which in a very quiet way appears to be doing a considerable amount of good in the way of spreading abroad a sound general knowledge of the laws of hygiene. "The National Health Society" has enrolled amongst its members men known for their attention to all matters relating to the public health—as Dr. Acland, Dr. Farr, Dr. Corfield, E. Chadwick, &c. A large number of philanthropic ladies share its work, and some of whom undertake to deliver lectures on sanitary matters. The society has now been established three years; it gives an annual course of lectures at the rooms of the Society for the Promotion of Social Science, and among those who have contributed to its state of knowledge we notice the names of Dr. Bartlett, Dr. Wilks, Miss Hill, W. Eassie, Dr. Humphry Sandwith, &c. The subject of the last-named gentleman's lecture was one of much interest at this moment—"The Water Supply of London." This lecture has been printed and distributed by the society. It is in every way an excellent and well-digested epitome of the water question. Dr. Sandwith holds that it is impossible to purify the contaminated source from which London now draws its water for domestic uses. He observes that while London is peculiarly favoured by Nature—a magnificent river running through it—the chief use we make of it is to turn it into a big sewer. Much stress, he adds, "has been laid on the importance of boiling doubtful water as well as filtering it, but the eggs of animalcules are not always killed by this process any more than by intense frost. The immense dilution of sewage thrown into a large river like the Thames has comforted most minds—my own among the rest before I studied the question—but this consoling view has been dissipated, and in the wettest climate in the world we are unable to get even a decent drinking water":

"Water, water everywhere, and not a drop to drink."

LAST week the police seized the goods of a number of persons at Banbury, as payment of fines imposed for non-compliance with the provisions of the Vaccination Act.

WE understand that Mr. Quain, the representative of the Royal College of Surgeons of England in the General Medical Council, has notified his desire to resign the post.

A BILL has passed the Legislative Assembly at Melbourne authorising medical schools to obtain anatomical subjects necessary for dissection and for teaching purposes.

AN afternoon performance in aid of the funds of the Samaritan Free Hospital is to be given on Friday next at St. George's Hall, London. Mr. Henry Irving is announced to recite Hood's "Dream of Eugene Aram."

A PERSON described as a surgeon, named Robert Forsyth Brown, was last week indicted for stealing a gold watch and a sum of money; the prisoner pleaded guilty to the indictment. The case against the prisoner was that for a few days he resided at a Tavern in Old Kent Road. Upon the barmaid going into her room she missed her watch from the dressing-table and £1 2s. 6d. in cash. She communicated her loss to her mistress, and the prisoner was watched. He became very indignant; but finding the potman was determined to detain him, he agreed to give him a half-sovereign. When taken to the police station, he produced the watch from his waistcoat, and asked if he could not "square things."—Two previous convictions were proved against the prisoner. The prisoner was sentenced to twelve calendar months' imprisonment with hard labour.

A BILL for the better regulation of English prisons is now on its passage through Parliament, and it will be succeeded as soon as may be, but possibly not this session, by a Bill to deal with Irish prisons. When that measure is introduced it will deserve the attention of the Irish Medical Associaton and of the county infirmary surgeons of Ireland, because the arrangement for medical attendance on gaols has long been anomalous, and the opportunity ought to be seized to amend it. By the 86th section of the 6th and 7th George IV., cap. 116, the surgeon of the gaol, if he be also surgeon to the county infirmary, is obliged to give his attendance and professional assistance to the prisoners and other inmates of the gaol without fee or reward. By another statute the salary to county infirmary surgeons granted by the grand jury ceased at the death of the holders then in office, and as many of them have died within the last ten years it has been necessary to make separate arrangements for the medical care of county prisons, which arrangements have been very unsatisfactory.

The election of the Council of the Irish College of Surgeons took place on the 5th inst. It was expected that the attendance of Fellows would be small, but the meeting of the Irish Medical Association attracted a large number of the College constituency to Dublin, and the voters were more numerous than was anticipated. One hundred and twenty Fellows voted. The whole of the nineteen outgoing Councillors offered themselves for re-election, as well as Mr. Hamilton, the outgoing President, and Mr. Corley, of the Richmond Hospital, the only new candidate. As Mr. Hamilton's readmission to the Council was almost certain, it was essential that one of the Council should go out of office, and there was a smart contest as to who the extruded member should be. On a scrutiny of the votes it appeared that the highest poll was 96, and the lowest of a successful candidate 66. Mr. Corley polled 65, and did not obtain the seat he sought, while Mr. William Stokes polled 60, and was not re-elected. The voting may be conceived to have been close, when we state that between the 11th elected Councillor and the last of the 19 successful competitors there were only 10 votes, there being one vote only between each of the three lowest polls.

— —

We noticed last week the extraordinary proceedings which took place at Toronto in connection with the medical examinations of the College of Physicians and Surgeons, it being alleged that more than one of the court was drunk, and that the Examination Hall was a pandemonium. The *Canada Medical Record* refers to the subject in its last issue, and says :—

"The programme was not adhered to, the reports concerning the written examinations in some instances not being forthcoming till long after the required time, thus compelling the oral examinations to be put over, and putting the students to considerable additional expense. This state of things is bad enough, but when it is openly stated that the cause of this delay was the over-indulgence of some of the examiners, the accustion is one of a very serious character. A Mr. King, under his own signature in the *Globe*, brings this charge against them, and although one of the Board—its chairman, if we mistake not—denies the accusation, the information which reaches us from several independent sources forces us to believe that the charge is not devoid of foundation. For instance, it is asserted that one of the examiners, while in a mood more jovial than correct, passing through a crowd of students waiting in one of the hals, pulled out some specimens from his pocket, and handing them to a student near him, asked him to describe them, saying at the same time he intended giving oral examinations on these specimens, and would like them to be well up on them. Information also reaches us that the same examiner, in the same condition, entered a billiard room and attempted to examine some students who had congregated there in the same irregular manner."

Correspondence.

THE PUFF DIRECT.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—Your readers need not be accused of flattering you when they give you praise for the course you have taken in exposing the manœuvres of the mischievous clique who have been doing their utmost to cause disunion in their profession by the establishment of the sham association alluded to under this heading by "Anti-Humbug" in your last issue. You have doubtless merely taken the trouble to inform yourself of the actual state of affairs, instead of like your contemporary, taking the word of one of your "young gentlemen" who had been—to use the most expressive terms—"*got at*" or "*nobbled*" by the clique in question. Your contemporary has not had the manliness to make the *amende honorable* and to retire with dignity from his false position, but with characteristic meanness has endeavoured to sneak from the field under the cover of apologetic phrases which are in reality more offensive than his open attacks. In the first place, not daring to refuse insertion to the disclaimer repudiating the Association, signed by twenty-five on behalf of more of the fifty surgeons practising dentistry in the United Kingdom, he has struck out in printing the protest what was very likely to influence many in the profession, and which was therefore prominently placed in the manuscript of the disclaimer—namely, the public appointments of those by whom it was signed. These appointments showed that the list included two present and two past examiners in dental surgery at the College of Surgeons, besides thirteen gentlemen holding appointments at the chief hospitals and medical schools in the metropolis. Your contemporary says he has consistently supported the Association because he believes that its members are actuated solely by an honest desire to elevate the status of the speciality, and that it reflects the aspirations of a large number of highly qualified dental surgeons, and that ample justification for its formation is found "in the laxity of the rules regulating admission into the Odontological Society, which cannot by its constitution be held to faithfully represent what is most advanced and most creditable in the speciality." Whether this statement arises from ignorance or from a deliberate desire to insult the signers of the disclaimer, it is equally offensive and unjustifiable. If he had inquired he might have ascertained that the good faith of at least the promoters of the Association is questionabl, since they are gentlemen who are well known in the dental profession as having either held aloof from or openly opposed the movements which have resulted in dental reform. Among the objects of the Association is said to be the promotion "of an improved code of ethics for dentists;" yet one of the projectors of the Association is actually a gentleman who now holds, or lately held, a patent for a toothbrush, a fact which has been stated in the journals. The rules of the Odontological Society rightly exclude practitioners guilty of the grossly unprofessional act of taking out a patent for any appliance used in the profession, not to say such a triviality as a tooth brush, and on this ground the connection of the gentleman in question with the Society has some time since been severed. A code of ethics which allows such conduct will be certainly a curiosity of literature, and will be waited for doubtless with anxiety. The promoters of the Association appear not to be aware that a cede of ethics in any profession has never been reduced to writing, and indeed that it must ever remain unwritten, the ethics being merely the expression of that innate gentlemanly feeling without a due proportion of which no body of professional men can be kept in union or work in harmony. "The laxity of the rules of the Odontological Society" are illustrated by the above statement, and, further, it may be mentioned to show the amount of truth in the complaint of your contemporary that these rules forbid in precise terms the admission of any but strictly professional men, and give summary power to the Council to suspend anyone guilty of unprofessional conduct; besides which every candidate's name has to be submitted to the Council, held over for four months in order that his character may be investigated, and then submitted to ballot by the Society. Now, Sir, the Society numbers among its members upwards of 150 dental surgeons holding full medical and dental diplomas; among them are several of the Universities, and Fellows and Members of the College of Surgeons, as well as licentiates in dental surgery. Some of them are men of great reputation, known by their works throughout the scientific world. If such a body does not represent what is "most advanced and most creditable in the speciality," and if it is not likely to be able to take care of itself and prevent the admission of improper persons to its ranks, perhaps your contemporary will kindly inform us where we are to look for it in the dental profession. Is it to be found in the minority of discontented busybodies who have started the Association, as your contemporary states? He knows, or ought to know, that it is not.

I remain, Sir,
Yours faithfully,
M.R.C.S., L.D.S.

ENGLISH SURGERY.

THE death of Captain Henry Eustace Leader, of Mill Street, in the county Cork, has given occasion for much comment in surgical circles in Dublin. Captain Leader, it is stated, died from the effects of an operation for the removal of a large and deep-seated encephaloid cancer, which presented itself as a tumour in the gluteal region. On the early development of the cancerous growth he was treated by the local practitioners, who, not being satisfied of the nature of the disease, sent him to Dublin, where he was seen by Mr. Butcher and Dr. Robert Smith, lately Professor of Surgery in the University, who at once diagnosed it encephaloid, and advised that—being deeply seated—it could not possibly be removed, or it would prove inevitably fatal, and not only gave expression to their opinion, but committed it to paper, signed by both of the consultants. It is stated that long afterwards, and when the tumour was further developed, the gentleman's friends induced him to go to London, where he was placed under the care of three surgeons of the highest eminence, who are stated to have advised an immediate operation for the removal of the growth, and held out hope of a speedy recovery. The report runs that on operation the growth was found—as the Irish surgeons predicted—deep-seated, and only a small part of it could be removed, and the patient died within a day or two. We have Mr. Butcher's authority for the statement that both he and Dr. Smith advised in the most emphatic manner against the performance of an operation, and distinctly predicted the result, and the case is regarded by the profession in Ireland as one of a too numerous class, in which patients whom Irish surgeons have conscientiously refused to touch have been subjected to operation in London without hesitation, and with apparent inappreciation of the great hazard to the patient.

Medical News.

Royal College of Surgeons of England.—The following Members having passed the required examinations for the Fellowship on the 25th, 26th, 27th, 29th, and 30th of May, were, at a meeting of the Council held on June 8th, duly admitted Fellows of the College :—

Clutton, Henry Hugh, L.S.A., Witham, Essex.
Cottle, Ernest W., B.A. Oxon., L.R.C.P.L., Savile Row, W.
Cretin, Eugene, L.S.A., Mauritius.
Godlee, Rickman J., M.B., M.S. Lond., Henrietta St., W.
Keetley, Charles R. B., Great Grimsby.
Lediard, Henry A., M.D. Edin., Cleveland Street.
May, Bennett, M.B. Lond., Birmingham.
Morgan, John H., M.A. Oxon., Chapel St., Park Lane.
Osborn, Samuel, L.S.A., Brixton.
Pepper, Augustus J., Barrowden, Rutlandshire.
Pope, Harry C., M.B., B.S. Lond., Birmingham.
Ransford, Thomas Davis, L.R.C.P. Lond., Salisbury.
Roechel, Joseph W., L.R.C.P. Lond., Bath.
Sanders, Thomas, L.S.A., South Molton, Devon.
Shuter, James, Tufnell Park, Holloway.
Tweedy, John, L.R.C.P. Lond., Harley Street.
Webber, W. Littleton, L.R.C.P.L., Modbury, Devon.

Of the 30 candidates examined on the above-named days, 13 failed to satisfy the Court of Examiners, and were referred for twelve months.

Pharmaceutical Society of Ireland.—The monthly meeting of the council of the above Society was held at the College of Physicians, Kildare Street, on Wednesday the 7th inst, Dr. Aquilla Smith, Vice-President, in the chair. The following members were present:—The Right Hon. the Lord Mayor, Mr. Wm. Allen, Dr. Collins, Dr. Frazer, Mr. J. Goodwin, Mr. Wm. Hayes, Mr. J. T. Holmes, Dr. Ryan, and Professor Tichborne. A letter was read from Mr. Myles Jordan, Crown Solicitor for co. Mayo, requesting a certified copy of the register of pharmaceutical chemists, as he had been instructed by the Attorney-General to prosecute in a case of illegal sale of poison. The council directed the Registrar to forward the copy as requested. Mr. Holmes moved the following resolution :—"That a circular requesting support to Mr. Errington's Amendment in Committee on the Juries Procedure Bill (Ireland) be forwarded by the Council to Members of Parliament." He said that at the last meeting of the council, a request had been forwarded to the Chief Secretary, asking him to include pharmaceutical chemists in the exemption clause of the Juries Procedure Bill. A reply had been received, in which Sir M. H. Beach stated that "as at present advised he did not see sufficient reason for exempting pharmaceutical chemists." A meeting had been held at which he (Mr. Holmes) had been deputed to endeavour to get some private member to urge the matter. He had applied to Mr. Errington, M.P., who at once took the matter up, and had given notice of an amendment exempting pharmaceutical chemists. It was understood that Sir M. H. Beach was strongly opposed to the amendment, on what grounds it was hard to say ; he could bring forward unanswerable arguments in favour of their exemption, but would simply state the fact that in England pharmaceutical chemists are exempt. The Lord Mayor said he had great pleasure in seconding the motion, he fully endorsed what Mr. Holmes had said, and considered it very desirable in the interests of the public that pharmaceutical chemists should be exempt from service, and was at a loss to understand why there should be exceptional legislation for Ireland in a case of this kind. A circular in accordance with the terms of the motion was drawn up by the council, and the Registrar was instructed to forward a copy to all Irish members of Parliament.

Vital Statistics.—From the Registrar-General's return we learn that during last week 5,826 births and 3,500 deaths were registered in London, and twenty-two other large towns of the United Kingdom. The mortality from all causes was at the average rate of 24 deaths annually in every 1000 persons living. The annual death-rate was 22 per 1000 in Edinburgh, 20 in London, 26 in Glasgow, and 23 in Dublin. The annual rates of mortality during the same period in the other large towns were—Norwich 26, Hull 19, Leicester 19, Portsmouth 25, Newcastle-upon-Tyne 23, Birmingham 21, Brighton 20, Leeds 24, Wolverhampton 30, Bradford 26, Sheffield 24, Plymouth 29, Bristol 20, Oldham 32, Manchester 27, Salford 32, Nottingham 17, Sunderland 26, and Liverpool 30. The annual death-rate from the seven principal zymotic diseases averaged 3·4 per 1000 in these towns, and ranged from 0·0 and 0·4 in Nottingham and Newcastle-upon-Tyne, to 7·9 and 10·2 respectively in Portsmouth and Salford. The high zymotic rate in Portsmouth was due to scarlet fever, and in Salford to small-pox. The deaths referred to small-pox in the twenty towns were 41, against 21 and 17 in the two previous weeks ; 23 occurred in Manchester and Salford, and 11 in Liverpool. Since the heginning of the year 305 fatal cases of small-pox have been registered in Manchester and Salford, including 74 in the Monsall hospital. In London, the 1,343 deaths included 4 from small-pox, 33 from measles, 45 from scarlet fever, 5 from diphtheria, 76 from whooping-cough, 21 from different forms of fever, and 13 from diarrhœa. To the seven principal diseases of the zymotic class 197 deaths were referred, against 186 and 187 in the two preceding weeks. These 197 deaths were 48 below the corrected average number from the same diseases in the corresponding week of the last ten years, and were equal to an annual rate of 2·9 per 1000.

POISONING BY GOAT'S MILK.

A LARGE number of cases of apparent cholera occurred lately in Rome under circumstances which led to the examining of the goat's milk used by the families affected by the disease. The goats were all found to be in full health and excellent condition, but on examining their fodder a number of poisonous plants were detected among it, among others hemlock and colchicum. It is well

known goats can eat large quantities of hemlock and tobacco without injury, but the similar innocuousness of colchicum—which acts powerfully upon cows—was not known before. Prof. Ratti examined the milk of these animals as well as the matters vomited by the affected persons, and detected in both considerable quantities of colchicin. (*New Remedies.*)

LIST OF ENTRIES IN THE REGISTER OF THE BRANCH MEDICAL COUNCIL (IRELAND) FOR THE MONTH OF APRIL, 1876.

APRIL 6th.—Warren, Samuel, 1 Abercorn Terrace, Merrion, co. Dublin, M.B. Univ. Dub., 1876.

11th.—Jenkins, Aneurin, Loughor Rectory, Glamorganshire, S.W., Memb. R. Coll. Surg. Eng. 1875, Lic. R. Coll. Phys. Edin. 1875.

13th.—Whitty, Patrick Joseph, Waterford, Lic. 1875 and Lic. Mid. 1876, R. Coll. Surg. Irel., Lic. K. Q. Coll. Phys. Irel. 1876.

17th.—Roberts, Browne, 11 Rathmines Road, co. Dublin, Lic. R. Coll. Surg, Irel. 1875, Lic. 1876 and Lic. Mid. 1876, K. Q. Coll. Phys. Irel.

25th.—Myles, Wm. Zachary, Richmond District Lunatic Asylum, Dublin, Lic. Apoth. Hall, Dub. 1875.

29th.—O'Connor, Lorenzo, Ballycastle, co. Antrim, Lic. R. Coll. Surg. Irel. 1875, Lic. 1876, and Lic. Mid. 1876, K. Q. Coll. Phys. Irel.

NOTICES TO CORRESPONDENTS.

☞ CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

READING CASES.—Cloth board cases, gilt-lettered, containing 26 strings for holding each volume of the MEDICAL PRESS AND CIRCULAR, can now be had at either office of this Journal, price 2s. 6d. The postal regulations not allowing the Journal to be stitched, these cases will be found very useful to keep each weekly number intact, clean, and flat, after it has passed through the post.

E. D. M.—The "Dr." who distributes his filthy pamphlet is a swindler, without any qualification, and the letters which he attaches to his name are a decoy for the public. The pamphlet being an indecent one, he could be prosecuted for issuing it under Lord Campbell's Act if its circulation could be brought home to him, which is a matter of great difficulty. More than one of these quacks has been successfully prosecuted, but the hindrances are almost insuperable. Meanwhile he would only derive advantage from our advertisement of him.

LIEBIG'S EXTRACT OF MEAT.—The Eleventh Annual Report just presented shows that the consumption of this article has become so great, and its position so firmly established in the public estimation, that the company founded by our late illustrious *confrère* is paying the handsome dividend of 10 per cent.

MR. H. B.—As soon as space permits.

DR. A.—We regret we cannot insert your communication.

MR. SPENCER WATSON is thanked.

DR. GARFIELD, OHIO.—The subscription, post free, per annum, to America is six and a-half dollars, payable in advance either to our agents in the States, or at our London office.

A HIGH-TITLED PRACTITIONER.

Of these titles he may boast,
For they form a splendid host,
And of one which by great Mars
Leaves the others all behind;
That's "Paid Puffer to some stars,"
Pleasant way to raise the wind.

PILL-BOX.

The above clipping is taken from the last number of *The Melbourne Medical Record*. We fancy that the Medical Directory of Great Britain could furnish many longer lists for satire than the above.

SOCIETY PROCEEDINGS.—The Transactions which appear in our present number have been in type for three weeks past, our space having been so materially occupied by the Medical Council proceedings. Authors of papers will please excuse the delay on this account.

DR. MELDON.—The address of the gentleman named is 18 East Twenty-ninth Street, New York. We believe he is still in practice.

A. Z. has forgotten to comply with our rule by omitting his name, which we require in every case as an evidence of good faith. It is particularly necessary in the present instance, as we must return the MS. our correspondent having in one or two parts of his communication left so much to the imagination that readers would fail to understand it in its present form.

MEDICAL CRITICISM IN THE STATES.—We are apt in this country to be not over nice in our criticisms of literary productions which do not come up to our beau ideal, but we doubt if anything ever appeared in an English Medical Journal of equal severity with that which we quote from our Cincinnati contemporary *The Clinic*. It appears that one Dr. Reed had read a paper before the Academy of Medicine in that city, which was afterwards published in a Medical Journal. This is too much for our enraged *confrere*, who forthwith accuses the author of giving as his own the writing of English medical men and stringing a lot of unacknowledged and incongruous sentences together, with some incomprehensible jargon of his own, winding up his criticism thus: "Such medical writing should be suppressed, and a pillory provided for the incarceration of an individual who inflicts such stuff on a society, and afterwards publishes it in a medical journal." Poor Dr. Reed.

COMMUNICATIONS, Enclosures, &c., have been received from Mr. Erasmus Wilson, London. Mr. Pomfret, Hollingworth. Mr. Popjoy, Accrington. Mr. Egan, Westport. Dr. Meldon, Dublin. Dr. Orlvie Will, Aberdeen. Dr. McCall Anderson, Glasgow. Dr. W. A. Byrd, Quincy, Illinois. Dr. Bastian, London. Mr. Stott, Disley. Dr. Shuttleworth, Royal Albert Asylum. Dr. Wilson, Leamington. Porter, Dublin. Dr. Stanley, Dublin, &c., &c.

VACANCIES.

Owen's College, Manchester.—Demonstrator and Assistant Lecturer on Anatomy. Salary, £100 per annum. Applications to the Principal.

Lancaster County Lunatic Asylum.—Resident Medical Superintendent. Salary commencing at £450. Mr. Sharp, Solicitor, Lancaster, will furnish full information.

Lancaster Infirmary.—House Surgeon. Salary commencing at £90. Applications to the President of the Infirmary.

York Rural Sanitary Authority.—Medical Officer of Health. Salary, £140 per annum. Application to Mr. Brearey, 1 Museum Street, York.

Bolton Union.—Resident Assistant Workhouse Medical Officer. Salary, £150. Endorsed applications to the Clerk of the Union.

St. Thomas's Hospital.—Resident Assistant Physician, and a Resident Assistant Surgeon. Salary attached to each office, £100 per annum, with board and residence. Address the Treasurer.

Westminster Hospital.—House Surgeon without salary, but with board and residence. Applications to the Secretary.

West London Hospital.—Assistant Surgeon, Honorary House Surgeon. Salary, £70. Applications to the Secretary.

Belgrave Hospital for Children.—House Surgeon. Honorary. Address the Hon. Sec.

Fulham Union.—Medical Officer for No. 1 District. Salary, £50 exclusive of fees, And a Medical Officer to the Workhouse. Salary, £80 exclusive of fees. Applications to be sent to the Union Offices, Fulham Road, S.W.

Downpatrick District Lunatic Asylum. Assistant Resident Medical Superintendent. Salary, £100, with board, &c. (See Advt.)

Newport Union, Louisburgh Dispensary District.—Medical Officer. Salary, £100, with fees extra. (See Advt.)

Deaths.

COLLINGWOOD.—On the 29th of May, at Corby, Joseph Collingwood, M.R.C.S.E., aged 66.

JENKINSON.—On the 4th of June, at the Leeds Public Dispensary, Harold Jenkinson, Senior Resident Medical Officer, aged 25.

JOHNSTON.—On the 2nd of June, of inflammation of the lungs, after a few days' illness, at his residence, Riversdale, Middleton, co. Cork, Benjamin Johnston, Esq., M.D. T.C.D., L. and F. R.C.S.I., &c., aged 59 years, deeply and deservedly regretted.

LINTON.—On the 29th of May, at Oundle, Charles Linton, M.R.C.S.E., aged 67.

MORRIS.—On the 26th of May, at Blackpool, Charles Henry Morris, M.D., aged 5[illegible].

PRITCHARD.—On the 24th of May, at Saltash, Richard Davison Pritchard, M.R.C.S.E., Staff Surgeon R.N. (Retired List), aged 58.

SHANNON.—On the 25th of May, at Brailsford, Thomas Edward Shannon, M.D., aged 42.

SMITH.—On the 2nd of June, from drowning, at Chichester, Sumner Wyke, the eldest son of Henry Smith, Esq., F.R.C.S., Wimpole Street.

IRISH POOR-LAW INTELLIGENCE.

IRISH MEDICAL ASSOCIATION.

THE annual meeting of the Irish Medical Association took place on the 5th inst. In the morning Dr. Croly, Chairman of Council of the Irish Medical Association, entertained a large number of the members of the profession at breakfast at the Shelburne Hotel, Stephen's Green. Among the gentlemen present were the Right Hon. the Lord Mayor, the President of the College of Surgeons, the President of the College of Physicians, the President of the Obstetrical Society, and most of the leading members of the profession in Dublin and the provinces. The meeting was held at noon in the Library of the Royal College of Surgeons. Dr. Chaplin, of Kildare, presided.

The President delivered his opening address, which we unavoidably hold over till next week.

REPORT OF COUNCIL 1875-76.

MR. PRESIDENT AND GENTLEMEN,—Your Council are gratified at being able to report favourably of the condition of the Association. The reorganisation scheme has proved to be very satisfactory in its operation.

At their first meeting, held 11th June, 1875, your Council elected Dr. H. G. Croly of Dublin their Chairman for the ensuing year; Dr. Morgan, Hon. Treasurer; Dr. Chapman, Hon. Secretary; Dr. Grimshaw, Hon. Sec. to Council; and Drs. Purcell, Jacob, J. W. Moore, and Pollock to be the other members of the committee of Council. Of the 39 officers for the year just ended, 26 were holding Poor-law medical appointments, 4 were retired Poor-law medical Officers, and 9 were not connected with the Poor-law Service. Of these 26 were resident in the country districts, and 13 in Dublin. The President and the four Vice-Presidents were not only Poor-law medical Officers, but residents of country districts.

The Coroners' Bill of last year was not proceeded with in Parliament; but a new Bill on the same subject has since been introduced to the House of Commons by Mr. A. M. Sullivan, which, however, was to apply only to the City of Dublin.

Your Council have given the Bill their earnest attention, and sent forward to the House of Commons a petition against the Bill in its present form, urging that legislation on the subject applicable to all Ireland was urgently needed; and your Council issued a circular to each Irish member of Parliament, in which they suggested the introduction into the new Bill of certain clauses affecting medical witnesses at Coroners inquests. In this circular your Council proposed that a mileage allowance should be granted to the medical witnesses for the expenses they incurred in travelling to the place where the Inquest was to be held. That a fee of one guinea should be paid to the medical witness for each day or part of a day that his services were required, and one guinea for his attendance at each adjournment of an Inquest; also that he should be paid a fee of two guineas extra in case a post-mortem examination by dissection was required. This Bill has just passed the House of Commons, and your Council regret to have to report to you that many of their suggestions have not been approved by the House of Commons; nevertheless several important changes in the original Bill have been made, and it has, consequently, become much less objectionable than when first introduced.

The Pharmacy Bill, which has since become law, was supported by your Council, who sent forward to the House of Commons a petition in favour of that Bill, as well as a circular to each Irish member of Parliament on the subject, controverting the objection raised against the Bill by "The Pharmaceutical Society of Great Britain."

Copies of resolutions 3 and 5, passed at last Annual General Meeting, on the subjects of Compulsory Superannuation to Poor-law medical officers, and proper remuneration to the sanitary officers respectively, were transmitted to the Local Government Board.

A Circular on the subject of abuse of Dispensary Medical Relief, quoting the observations on that subject in the last report of the Local Government Board, and also containing a copy of resolution 8, passed at last Annual General Meeting of this Association, has been sent to the Hon. Sec. of the Committee of management of every Dispensary Committee, to which several replies were received. Much good has resulted from this communication, as many Dispensary Committees have attempted to check the abuse complained of; but it is to be regretted that all these bodies have not used their best exertions in the interests of the Ratepayers, as well as of the medical officers, to put a stop to this species of imposture.

By this Circular of the 18th September, 1875, the Local Government Board informed the dispensary medical officers that the Justices now have power to order the Guardians to pay such medical officers for each examination of alleged dangerous lunatics, such fee, and other expenses, if any, in the aggregate not to exceed two pounds. It has been decided by the authorities that *only the dispensary medical officers* are entitled to receive remuneration for making these examinations; and your Council would advise the dispensary medical officers, whenever they are called upon to examine alleged dangerous lunatics, to apply to the Justices for an order on the Guardians to pay (as provided by Sec. 14 of the Lunacy Amendment Act) such fee as they allow. The dispensary medical officer having received such order, should forthwith send it to the Guardians, and request payment thereof, and any refusal on the part of a Board of Guardians to recognise the Justices' order should be reported to the Hon. Sec. of this Association.

In compliance with resolution 4, passed at the last annual general meeting of this Association, your Council

have given their best attention to the grievances of the registrars of births and deaths; and Dr. Purcell, who has special charge of that department on the Committee, devoted much valuable time to the subject. A new Bill has been drawn up and printed, with the view to amend the Registration of Births and Deaths (Ireland) Act of 1863. The Bill was entrusted to Mr. Gibson, Q.C., M.P., to lay before Parliament; but as the session had so far advanced, Mr. Gibson thought it more advisable that the proposed Bill should be submitted to the House of Lords in the first instance; and with this view he transferred the Bill to the Right Honourable the Earl of Donoughmore, with whom some members of your Council have had a conference upon its details. The Earl of Donoughmore being of opinion that the Bill would be likely to be adopted by government, advised that it should be sent to the Chief Secretary for Ireland, and this suggestion was acted on; but the Chief Secretary's views have not as yet been ascertained.

Your Council expect that new legislation on this very important subject will take place, and they have reason to hope that the principles of the Bill they have proposed will be adopted. If their Bill became law, many, if not all, of the grievances of the registrars will be removed, and the increased remuneration obtained. The law in Ireland will be, in all desirable respects, assimilated to that in force in England, and registration will be made more perfect.

The interests of the Infirmary surgeons in Ireland, in connection with Mr. Gibson's and Mr. Meldon's Bill's have received the attention of your Council; but in the present state of public opinion, with regard to the County Infirmaries, they deemed it more prudent not to take any action in the matter, lest the positions of the Infirmary Surgeons should be endangered rather than improved by their interference, your Council being aware that the authorities contemplated abolition of these institutions, and utilisation of the workhouse hospitals in their stead.

The subject of vaccination in Ireland having been brought under the notice of Parliament by Mr. Meldon, M.P., your Council communicated with Mr. Meldon, and supplied him with full information on the subject; and specially drew his attention to the disparity existing between Ireland and England in the matter of remuneration for public vaccination. Subsequently a deputation of the Council waited upon Mr. Meldon, who is now thoroughly conversant with this important subject, and who has promised to avail himself of the earliest possible opportunity of raising the question again. Mr. Meldon proposes to ask the Government to bring forward a new vaccination bill for Ireland next session, and in the event of the Government declining to do so, he has requested that a draft of a suitable bill should be submitted to him by your Council, who have undertaken to comply with the request; but owing to the great pressure of business of late the preparation of the draft bill has not yet been completed; it shall, however, receive early attention.

A very important case, affecting the interests of dispensary medical officers, has recently been decided—viz., Dr. Kisby, Medical Officer of Ballyfurnan Dispensary District, having been requested by the relieving officer of his district, upon the authority of the guardians of Boyle Union, to attend at petty sessions and give evidence in cases of prosecutions of defaulters under the Vaccination Acts, complied with the request, and obtained from the justice s presiding at petty sessions an order on the guardians to pay him a fee of one guinea for his services (as specified in Section 13 of the Vaccination Amendment Act), which he forwarded to the guardians, requesting payment. The guardians refused to pay the claim, on the ground that Dr. Kisby had incurred no expense, inasmuch as the petty sessions were held in the town in which he resided: whereupon Dr. Kisby appealed to the Local Government Board, and was informed that that board declined to interfere in the matter.

The ruling of the Local Government Board appears to be that whenever cases of prosecution against defaulters under the Vaccination Acts are tried at a Court held in the town in which the medical officer resides, they do not support his application for remuneration; but if he has to travel a distance to another town, they recommend the guardians to pay him the amount of fee certified by the magistrates. The law, however, makes no distinction between the medical officer who has to travel and the one who has not—both are unquestionably entitled to remuneration for their services, the one who has to travel a distance being admittedly entitled to the fullest consideration.

Dr. Kisby's claim not being supported by the Local Government Board, he brought it under the notice of your Council, who urged Dr. Kisby, in the interests of the profession, to persist in his demand; and your Council undertook to defray the expenses of a trial of the case at quarter sessions in the event of his being nonsuited. Dr. Kisby consented to this request, and the case was tried before the chairman of quarter sessions, who decreed against the guardians, and ordered them to pay Dr. Kisby's fee of one guinea, twelve shillings and sixpence expenses to a witness, and the costs of the trial.

At the hearing of this case the chairman expressed his opinion that medical practitioners could not be compelled to attend at court and give evidence without being remunerated. Your Council would recommend all dispensary medical officers who are requested to attend at court and give evidence in prosecutions of vaccination defaulters to comply with such request, and to apply to the justices for an order on the guardians for payment of a fee (under section 13 of the Vaccination Amendment Act), and to forward same to the guardians, with a request that it be paid.

The guardians of Boyle Union appear to have learned a salutary lesson by Dr. Kisby's case, for very recently Dr. Drapes, of Keadue, claimed from them two pounds, the amount certified by the justices for his examination of an alleged dangerous lunatic, which this board of guardians paid forthwith.

Dr. Spencer, of Burton, Port, Letterkenny, communicated the following case to the Council:—

He had been requested by the relieving officer of his district, with the authority of the guardians of the Union, to attend at court and give evidence in cases of prosecutions of defaulters under the Vaccination Acts. Dr. Spencer being aware that all the odium attaching to these prosecutions was attributed to him, to the detriment of his private practice, declined to attend and give evidence unless summoned by the court.

When the cases came on for trial they were dismissed, in consequence, as the guardians alleged, of Dr. Spencer's absence; but as he alleges, there being no person to prosecute, as recorded on the register of the court.

The Guardians reported the matter to the Local Government Board, and requested that Dr. Spencer be dismissed. The Local Government Board asked Dr. Spencer for an explanation, and submitted the matter to the Committee of management of his dispensary district, who passed an unanimous vote of full confidence in Dr. Spencer. In reply to Dr. Spencer's explanation, the Local Government Board informed him that if he refused to attend "voluntarily" in court in such cases in future, he must be prepared to accompany such refusal with his resignation; to which Dr. Spencer replied, that he had no desire to be obstructive, and in future would comply with such requests, whereupon the Local Government Board directed the Guardians to let the matter end. In the course of time the Guardians were called upon to pay £2 1s 3d. the amount of the costs incurred in the dismissed cases. The Guardians called upon Dr. Spencer to pay that amount, and directed their clerk to institute proceedings at law against him in the event of his refusal. In order to avert the proceedings threatened, Dr. Spencer, under protest, sent half notes and stamps for the amount to the guardians, and sought the advice of your Council; who, having considered all the circumstances of the case, saw

no other course open to Dr. Spencer than to appeal to the Local Government Board. At the same time they were of opinion that if Dr. Spencer had allowed the proceedings to go on, the amount claimed probably could not have been recovered from him. Dr. Spencer was, soon afterwards, served with a Civil Bill Process, whereupon he sent the remaining half notes to the guardians. In reply to his appeal to the Local Government Board, he was informed that that Board declined to interfere in the matter.

Your Council thought the question involved in this case one which they should obtain a legal opinion on; and accordingly Mr. John Mallet Williamson, solicitor, was instructed to prepare a case for the opinion of Mr. Gerald Fitzgibbon, Q.C., as to the legality of the power assumed by the Local Government Board in ordering dispensary medical officers to attend at court and give evidence in prosecutions of defaulters under the Vaccination Acts, upon the direction of the guardians, and without receiving a summons from the court; and also as to whether they could claim remuneration for such services.

Mr. Fitzgibbon's opinion is to the effect that the dispensary medical officers acting as public vaccinators are not bound to take part in prosecutions; that the fact of the medical officer's certificate being legal evidence tends to show that his personal attendance at prosecutions was not contemplated by the legislature; that his absence need not necessarily be fatal to a prosecution; whilst his attendance at court may be seriously injurious to, if not inconsistent with, the due performance of his professional duties; that the Local Government Board cannot prescribe a duty not imposed by statute; that a medical officer cannot be compelled to attend at prosecutions, unless by a summons from the court, the same as any other person: and that his refusal to attend without summons would not afford legal ground for depriving him of his office. He is also of opinion that it is the duty of the authorities directing the prosecutions to provide sufficient evidence without trespassing on the time of the medical officers, or to fairly remunerate them; but that however clear their rights may be, they are not capable of being enforced; that the fee for vaccination does not include payment for attendance as a witness; that every medical officer who attends any prosecution ought to apply for a certificate for his expenses, which the justices ought to grant, though they cannot be forced to do so; and lastly, that if the medical officers refused to attend at prosecutions, the guardians might obtain summonses, and compel them by *subpœna* to attend, so that they would gain nothing by resistance, which would only aggravate this substantial grievance; their only course being to endeavour to obtain from the Local Government Board a regulation which will either preclude the necessity for their attendance, or fairly remunerate them for such services; or to seek redress from Parliament.

Your Council also deemed it desirable to obtain an opinion of counsel as to the legality of the powers assumed by the Local Government Board in ordering sanitary officers to "*attend at and assist in all proceedings*" in cases of prosecutions under the Public Health Act, upon receiving notice so to do from the executive Sanitary officer, and without being summoned by the court; also whether the sanitary officers could claim remuneration for such services; and, accordingly, Mr. John Mallet Williamson, solicitor, was instructed to prepare the case for the opinion of Mr. Robert O'Brien Furlong. Mr. Furlong's opinion is to the effect that the Local Government Board has power to order sanitary officers to "attend at and assist in all proceedings" upon being directed so to do by the executive sanitary officer; that it is part of the duty of the sanitary officers to so attend, without being summoned by the court; and that they are not entitled to any fees as witnesses, inasmuch as the additional salaries paid to them, under the Public Health Act, was intended to compensate them for the duties imposed, of which this is one; but that the legislature intended the remuneration to be *just and reasonable;* that the duty is, no doubt, an invidious one; but he does not see how it could have been avoided, as medical testimony may often be essential to the success of these prosecutions. In conclusion, he thinks it unfortunate that district medical officers of health have not been appointed, who should be debarred from private practice, and who would take the odium and responsibility of carrying out the Health Statutes, without risk of loss of private practice.

The grievances of militia medical officers have been under the consideration of your Council.

There are a great many surgeonships and assistant-surgeonships of militia regiments vacant—no new appointments having been made for some months. The War-Office authorities are preparing a new warrant to regulate militia medical appointments,&c., and it is expected that this warrant will soon be issued. When it is published, your Council will give it due attention, and endeavour to have the militia medical officers placed upon a proper footing.

The insufficiency of the remuneration allowed to civil medical practitioners in charge of military troops in Ireland has been brought under the notice of your Council, and a resolution on this subject will be submitted to this meeting. Your Council consider that the remuneration for this service should not be less than that given for attendance upon the Royal Irish Constabulary, which is almost a similar duty.

Your Council received a letter from Dr. Scully, jun., of Clonmel, Hon. Secretary to the "County Tipperary Medical Protective Association," requesting that that Association, in consideration of an annual subscription of three pounds, should be affiliated as a branch of this Association, and that each of its members should thereby be members of the Irish Medical Association. Your Council replied that Rules Nos. 2 and 20 prevented them entering into the arrangement suggested, which would require the assent of an Annual General Meeting; and they are of opinion that it would not tend to the interests of this Association to have it broken up into branches. By such a course they believe the influence of this Association would be prejudicially affected, and that the independent existence of the County Tipperary Association would not only render its exertions less useful, but would continue that disunion in the profession which is so much to be deprecated. At the same time, your Council highly approve of local meetings being held by members of this Association under the one common banner; and consider that the proposition of the County Tipperary Association would best be met by their working expenses being defrayed by this Association upon all their members becoming individual members of this Association, which they hope will meet with the approval of this meeting, as well as of the members of the County Tipperary Association.

Dr. John MacDonnell having resigned his office as Medical Commissioner, Local Government Board, and a rumour to the effect that the appointment would not be filled up having reached your Council, they sent a petition to the Lord-Lieutenant, praying that a medical practitioner be appointed to the vacant commissionership, and Dr. Croker King was promoted to that office. Your Council then fearing that the vacancy in the medical inspectorship, caused by Dr. Croker King's promotion might not be filled up by the appointment of a medical practitioner, sent a petition to the Lord-Lieutenant, praying that a medical practitioner be appointed inspector, and Dr. M'Cabe has been appointed to the office.

Your Council also brought these matters under the notice of the College of Physicians and the College of Surgeons in time for these bodies to bring the weight of their influence to bear upon the authorities.

Your Council, finding that the duties of the hon. secretary were so onerous, and that the funds of the Association would admit of it, authorised the hon. secretary to appoint a clerk at a salary of thirty pounds a-year, to perform such duties as the hon. secretary required of him, who should hold office only during the will and pleasure of the hon.

secretary, and an appointment was accordingly made on the 1st February last.

It having been brought under the notice of your Council that the Public Health Committee of the Corporation of Dublin convened a special meeting of the medical sanitary officers to consider the cause of the inordinate death-rate of Dublin, and to suggest a remedy. That such meeting was held, and that the medical sanitary officers presented a statement of their views, and that the Public Health Committee ignored that statement when reporting their proceedings to the Local Government Board. Your Council passed a resolution expressing their disapproval of the course adopted by the Public Health Committee, in suppressing the statement of the medical sanitary officers, and directed that same be communicated to the Public Health Committee, and also to the Chief Secretary for Ireland. This matter has been brought under the notice of the House of Commons by Dr. O'Leary, M.P., and your Council consider that the conduct of the Public Health Committee in this matter was a slight to the profession which they were bound to take notice of.

Your Council, with very deep regret, have to announce the deaths of several members of the Association, which occurred during the past year, viz.:—

Dr. Hynes, of Kinvara, Vice-President for the province of Connaught; Sir William Wilde, Surgeon-Oculist to the Queen; Drs. Barrett, of Kilcullen; O'Rorke, of Enniscorthy; and Pollock, of Dundalk; also Dr. John Morgan, Honorary Treasurer of the Association. Up to the time of his death Dr. Morgan was a most active member of the Committee of Council, and took a deep interest in the welfare of this Association. During the past year he submitted to your Council the draft of a scheme by which he hoped, to some extent, to prevent the too frequent abuse of the system of dispensary medical relief at present occurring. Dr. Morgan proposed that your Council should draw up a scale of small fees, proportionate to the incomes of persons of small means, based on the valuation of their holdings, and recommend the adoption of same to the medical practitioners of country districts. He believed that, if adopted, his suggestions would be fraught with benefit to these gentlemen, whose incomes would thereby be increased and hardships diminished, while their professional dignity would not be compromised. Your Council though considering the suggestion in many respects good, thought it better not to recommend it at present to the country medical practitioners, nor until their opinions were received on the subject. Dr. Morgan undertook to modify his scheme, and submit at some future time, when he was suddenly cut off by the hand of death. A resolution of condolence with Mrs. Morgan in her bereavement was passed by the Council, and forwarded to her. Dr. Chapman, Hon. Sec. undertook the duties of Hon. Treasurer until a successor to Dr. Morgan was appointed. There remains in Bank to the credit of the Association, in Dr. Morgan's name, a balance of £46 0s. 4d.; but, until some legal formalities have been complied with, this sum cannot be transferred to your Hon. Treasurer.

Dr. Nolan, of Gort, was promoted to be vice-president for Connaught, in room of the late Dr. Hynes; and Dr. Kerans, of Ahascragh, was selected to fill the vacancy on Council caused by Dr. Nolan's promotion.

Your Council have had under their consideration the subject of amalgamating the Poor-law Medical Officers' Association with this association, and have received from Dr. Speedy, the hon. treasurer, a letter, dated 26th May, 1875, stating that if four members of the Poor-law Medical Officers Association were elected to the new Council, that association was willing to unite. Your Council consented to this proposal, and approved of the names of the four gentlemen nominated by Dr. Speedy. These names will be found placed first on the ballot paper, and your Council hope that you will elect these gentlemen *unanimously*, and so complete the amalgamation of the two associations.

(The letter referred to from Dr. Speedy was then read.)

Your Council regret that, owing to the great pressure of business during the past year, they have found it impossible to devote attention to the consideration of a scheme to provide for the widows and orphans of medical practitioners in straightened circumstances. This matter, however, should not be lost sight of, whenever a favourable opportunity for considering it occurs. For the present such cases must only rely upon whatever the funds of the Royal Irish Medical Benevolent Fund can bestow; and they would take this opportunity of commending that valuable Institution to the consideration of the members of this association.

In concluding their report, your Council are aware that all the grievances and hardships of the medical officers of the public services have not been removed, though they have, to the utmost of their ability, discharged their duties; and that still there is ample scope for exemplifying the usefulness of this association. The duties of the sanitary officers, as well as the utterly inadequate remuneration they receive, are subjects demanding the most earnest attention of this association; and your Council are hopeful that an opportunity may now be afforded of having the sanitary officers' grievances redressed, as a new Bill to amend the Public Health (Ireland) Act has been introduced to Parliament on the 30th May. They have therefore, to commend this Bill to the immediate attention of their successors in office, and to entreat most earnestly that each member of this association will use his utmost influence with his representatives and friends in Parliament to persuade them to do justice to the sanitary officers of Ireland *now*, as there may not soon again be an opportunity of doing so. This matter is so urgent, that your Council would impress upon the members, one and all, to be up and doing, without a moment's loss of time, as the value of such help cannot be over-estimated.

Mr. Furlong's opinion, with regard to the duties and remuneration of the sanitary officers, plainly showing that their position under the existing law and regulations is deplorable; and that if the present opportunity be not universally taken by the sanitary officers themselves individually, as well as by the profession generally, and its representative bodies, the present state of affairs may be perpetuated. Now is the time to work and every man should put his shoulder to the wheel!

The unsatisfactory state of the law, with regard to public vaccination in Ireland, is also a subject which demands the attention of this association.

There are other subjects of importance to be dealt with which will require all the influence and exertions of this association to effect.

Whilst your Council are gratified at being able to report that this association has achieved, in the past year, a considerable accession of strength, in the large number of new members, they must express their regret and surprise that there still remains a large number of medical practitioners throughout the country who have not become members, and they believe that the apathetic might be induced to support this association if the members generally undertook to canvass their neighbouring brethren to join its ranks; not only because it is the interest of the profession at large, but also that of every individual member of it, to do so. And your Council would remind each member of the profession that no matter what his individual interest might be, it is cared for and undertaken by this association, which is now the chief medium of expressing the opinion of the profession in Ireland. The interests of the medical officers of the public services, whether they be naval, military, militia, infirmary, or poor-law officers, or private practitioners solely, are alike promoted and protected by this association to the utmost of its abilities.

The following gentlemen form the new Council:—

President, G. H. Kidd; Vice-President, Robert MacDonnell; Council, William Colles, Richard G. H. Butcher, Alfred H. M'Clintock, George H. Porter, Professor M'Dowell T.C.D., Albert J. Walsh, T. Jolliffe Tufnell, Edward Hamilton, Edward Ledwich, Rawdon Macnamara, John K. Barton, Edward D. Mapother, Archibald H. Jacob, Philip C. Smyly, John Denham, Henry Wilson, John Cronyn, William I. Wheeler, and Samuel Chaplin.

In consequence of the length of the Report of Council we are compelled to postpone the further proceedings until our next.

The Medical Press & Circular.

THE NATURAL HISTORY OF PULMONARY CONSUMPTION. (a)

By A. B. Shepherd, M.A., M.B., F.R.C.P.,

Physician to the Victoria Park Hospital for Diseases of the Chest; Assistant Physician to St. Mary's Hospital; &c.

LECTURE I.—(Continued.)

Let us turn for an instant to the comparative pathology of these modern days. I have here a series of diagrams, copied, by his permission, from the second part of Dr. Klein's work. On the table is a drawing of the naked eye appearances of the lung in a case of acute tuberculosis in a child, together with microscopical preparations of a case of the same kind, made for me by Mr. Lithgow, our assistant-curator at St. Mary's; the latter show perivascular growth, with some lobular collapse, and but very slight catarrhal product. [A description of the diagrams, &c., followed here.]

In these two diagrams (Figs. xxiv. and xxvi.) it is possible to see in the lung of the guinea-pig, as well as in that of the child, certain histological products which it has been attempted, not for the first time in the history of "tubercle," to set up as the specific elements of that growth. Happily these giant-cells will soon be relegated—if they be not even now relegated—to the list of ordinary epithelial cells, the limbo in which rest already the pathognomonic tubercle-corpuscle and cancer-cell. As my friend Dr. Klein informs me, and as I am quite prepared to believe, the giant-cell is but an epithelial cell growing under certain conditions. But

"Each month is various to present
The world with some development,"

and the specific element refuses still to be unrecognised; this time it appears under the form of the particular cells drawn and described by Rindfleisch in Ziemssen's *Handbuch des Respirations-Apparates* (vol. ii. p. 161. Leipzig, 1874). I am perfectly prepared to see these cells, also, sink to the same position as the Riesenzellen. I confess that I do not perceive why, in the pursuit of a supposed scientific truth, the same common-sense which men use, or ought to use, in the ordinary affairs of life, should not exert itself; and when through the long list of specific structures, started by one author only to be hunted down by another, we find always the same untimely death, I believe that the very best thing we can do is not to join in the shadowy chase, but to abjure, as something that oppresses us, with no fault of our own, this "specific" incubus.

With the results shown in those diagrams and described in his work by Professor Klein, the researches of Dr. Burdon Sanderson and Dr. Wilson Fox in the main agree. But the latter writer goes much further, and states that he finds "in the lungs of patients dying of phthisis almost identically the same changes as those found in the lungs of children dying of acute tuberculosis"—a sentence to which I cannot altogether give my adhesion. There are cases, no doubt—cases of which I hope to speak more at length hereafter—in which the physical signs and symptoms of lung-disorganisation are followed by death, with all the symptoms of this "acute tuberculosis." But there are also cases, of not infrequent occurrence in the adult, of this same "acute tuberculosis" with almost the same series of clinical symptoms, and the same pathological changes, as far as I am able to make them out, as those found in artificial tuberculosis, and in the general tuberculosis of the child. The only case of the kind which I remember to have come almost entirely under my own observation that of a young man, about twenty-one years old. In him there were no abnormal signs on percussion; the respiratory sounds were everywhere coarse. There was increase in temperature and pulse-rate; his chest and abdomen were covered with sudamina; he was admitted into hospital as a case of probable acute tuberculosis, or doubtful typhoid; within a short time, he died with symptoms of tubercular meningitis, and his body presented the expected changes.

And it was, I think, from these comparatively rare cases

(a) Goulstonian Lectures.

in the adult that observers and writers argued that "ista tubercula (seu tumores)"—I use the words of Morton—underwent a further, and that a cheesy change, resulting—not in these cases, which, if the argument be true, must be said to die before such changes can take place—but in cases the clinical symptoms of which are entirely different, in a larger or smaller destruction of pulmonary tissue. That I am not, Quixote-like, opposing some image of my own brain, is, I think, shown by the fact that writers of the present day still class these cases of "acute tuberculosis" with "pulmonary consumption;" though it is but fair to state that Dr. Douglas Powell has, in his small work, drawn the distinction which others, though by no means all, have failed to make. I need not travel far for an illustration. In a very valuable, because very true and practical, though it may be a very simple paper on the different forms of pulmonary consumption by my colleague Dr. Peacock—a paper published originally in *St. Thomas's Hospital Reports* for 1870—are given two cases, "selected from numerous instances of the same kind;" together with a third, which differs from them in several respects; all three classed by the writer under the name "acute constitutional phthisis." Dr. Peacock's first case was that of a young lady, aged 22, who died on the twentieth day of her illness of apnœa. Four days before death, "the respiratory sounds were found everywhere harsh . . . but there was no rhonchus and no marked deficiency of the resonance on percussion in any part of the chest." These signs were slightly modified the day before death. On *post-mortem* examination, the body "was thin, but not emaciated." There were old pleuritic adhesions over a large portion of the left lung; the right lung was collapsed. "Both lungs were copiously infiltrated throughout their whole substance with miliary tubercles, having an average diameter of from half a line to a line, and uniformly of a yellowish-white colour . . . In no part had any of them undergone softening." Nothing is said about the head or abdominal organs. The second case is also that of a young woman, aged 24, who died after an illness lasting over three weeks of capillary bronchitis; here was the same absence of phenomena on percussion and auscultation; but little emaciation of the body, a chest sufficiently broad and expanded; both lungs contained a copious deposit of small, round, yellowish-coloured and semi-transparent-looking bodies, which in no part had softened; the bronchial glands were softened to a brown-coloured pulp; the abdominal viscera were free from tubercle. Dr. Metzquer in a *Clinical Study of Galloping Consumption*, published in Paris in 1874—and I may mention, in passing, that, to the majority of French writers, galloping phthisis is synonymous with acute tuberculosis—Dr. Metzquer gives two similar cases. Case 1 is that of a female aged 28-30, free from history of hereditary phthisis, and always well till she was taken one day with pains in the head and back, intense fever, rigors, and ringing in the ears. There were no signs on percussion or auscultation, though a few days later there were rhonchi and râles in both lungs, and streaks of blood in the sputa. Death occurred a month after the commencement of the illness, and there were "tubercles in all organs." The second case, that of a man, aged 43, is precisely similar: the same absence of hereditary phthisis and physical signs on the part of the lungs; the same general tuberculosis without softening. In both these cases there was some diarrhœa and slight jaundice before death. It would be easy to multiply from modern literature cases of this kind, but I prefer to turn back again to the commencement of the century. I quite agree with M. Thaon that Bayle's cases numbered 4, 14, and 15, named by him cases of granular phthisis, do not answer (see Andral, *op. cit.*, iv. 10), either clinically or pathologically, to this "acute tuberculosis;" but, in spite of the distinction Bayle makes between the *miliary tubercles* found in the lungs of his first case, a woman aged 20, who seems to have exhibited as her chief symptoms those of "tubercular peritonitis," and the *miliary granulations* in the lungs of his second case, a postillion aged 24, who died, as the four cases I have just quoted from Drs. Peacock and Metzquer did, from apnœa, both of them agree in these three points, that neither had any of the physical signs of phthisis pulmonalis during life; neither was emaciated, but rather both were remarkably plump; and both presented pathological products elsewhere as well as in the lungs. His cases 7 and 8, of men aged respectively 45 and 24, are very similar. They are the more interesting that, in addition to the lung-changes found, the cerebral symptoms which were chiefly exhibited during life left some after-death results; while the author himself adds in the title of the last "Death from a disorder of the brain" (Barrow's translation of Bayle: Liverpool, 1815, p. 173). In case 7, "there was near an ounce (of serum) at the bottom of the skull, which was as turbid as that contained in the lateral ventricles." (*Ib.*, p. 171). In case 8, there was what some pathologists would call now-a-days a "scrofulous" tumour in the medulla oblongata, and a collection on the surface of the brain of miliary round bodies of a dull opaque white, which may have been only Pacchionian bodies. But both cases again agree in these points: the most marked symptoms during life were not on the part of the lungs; the pathological products were presumably those found in general tuberculosis; the writer distinctly tells us there was no emaciation in either.

It would be but time wasted to quote similar cases. My own views as to the pathological products found in all these cases of "acute tuberculosis" are briefly these: There are found frequently together, sometimes alone, numerous vesicular pneumonias, collections of lymphoid cells round the vessels or round the smaller bronchi, or—and the distinction from the two last is by no means easy—proliferation of the nuclei in the wall of the capillaries themselves. Each of these products to the naked eye is exactly like the typical tubercle of authors, and without injection of the tissue and microscopical examination, cannot be distinguished from either of the others, except that, in cases where the vesicular pneumonias are the sole or almost sole production, the lung on section does not present to the hand that feeling of points standing out from the surface; though later, in a shorter or longer period after removal from the body, the lung-tissue collapses and sinks away, leaving the solid nodules more prominent. Such was the case here, (*a*) in which even the skill of Mr. Hurst did not catch them in their original superficial flatness.

I have purposely abstained from quoting cases of general tuberculosis in children under my own observation, because I find that they are only examples of what has been stated and illustrated by authors, who have expressed in a far better manner than I can do ideas which carry with them, at least to my mind, the impress of truth. But if, in addition to the evidence not only adduced for the purpose by writers like Buhl, but unconciously present in the observations of older workers, there were needful, for my own decision, facts within my own knowledge and my own reasoning, they also are forthcoming to uphold the statement of others beside Buhl that acute miliary general tuberculosis is a disease of absorption and infection. And this conclusion, in the very case I am about to state, is the exact contradictory of the older theory—that of Laennec—inasmuch as he considered the larger areas of softening and destruction to be due to the smaller disseminated product, which we hold to be the consequence of some older caseous centre. The one case I wish to mention is this. At the commencement of January, 1871, a boy aged 10 was brought to the Children's Infirmary with marked dulness at the left apex; no increased vocal resonance or tubular breathing; tympanitic resonance over the right chest, which measured a quarter of an inch more round than the left. The pulse was 90; the temperature 98·2. Towards the end of the month, there supervened diarrhœa and night-sweats. Admitted into the hospital, the boy improved in general health, without much change in the physical signs up to the commencement of April. In the second week of July in the same year, he was brought back. The left side was

(*a*) Drawing of lung of child: acute tuberculosis: catarrhal pneumonia most marked.

flattened from above downwards. There was absolute dulness over the whole left front; less absolute behind. On coughing, there was tubercular breathing, and slight crepitation at the end of expiration. The voice-sound was rather ægophonous and diminished in loudness. The right side was normal. There was no cough; no pyrexia to hand. The bowels were now constipated. Four days later, there was sickness. On the 25th of the month, he was readmitted in the drowsy state of tubercular meningitis. Early on the morning of August 3rd, the fifteenth day after the certain diagnosis of the tubercular meningitis, he died, his temperature the night before having been 102·3: and on the afternoon of that day we made a *post-mortem* examination. The result was as was to be expected: the left lung consolidated; the vesicles filled with cheesy deposit; in the apex, a cavity which communicated with a half-chalky, half-cheesy mass in the position of the thymus, making its way apparently into the pericardium; perivascular nodules in the pia mater; small miliary tubercles elsewhere; cheesy bronchial glands. The only comment I can make on this case is this: As a matter of reasoning, it must either be allowed that the antecedent presence of miliary tubercles which, according at least to the language of some, had caused the changes in the lung, gave no fatal indication till they appeared in the adventitia of the pia mater; or—and I confess the conclusion is easier to my mind—the presence of these perivascular nodules was in all the organs of the body simultaneous, or almost so; later than, and in every probability secondary to, the lung-changes which had already proceeded. There is no need to look upon the cheesy mass in front of the trachea as the original focus; though, as a pathological curiosity, its connection with the lung, and the thinning it was causing in a portion of the pericardium, is extremely interesting. There is one more point connected with this case, to which I may allude later on, which shows the probably hereditary character of what I assume to be the original disease. A younger sister and brother, of whom the latter died, both exhibited symptoms of pulmonary change, commencing, as it did in this boy, at the left apex. I cannot lay my hand on any notes of, nor do I remember making, a *post-mortem* examination of the younger boy. In all probability it was not allowed.

In everything I have said about this so-called "tubercle" to-day, I have confined myself altogether to that description of it by various writers as applied by them entirely to its supposed presence in the lungs. Unhappily, as I have already hinted, conclusions made as to its occurrence or supposed occurrence there, whether histologically as homologous growths, or pathologically as heterologous products, have been referred to the occurrence of "tubercles," neither histologically nor pathologically similar, in other organs. Backwards and forwards, from its implied type in the lung, its somewhat less defined repetition elsewhere, has this word "tubercle" been tossed, till, if it could speak for itself, it would make of men the same complaint which men, according to Plautus, make of the gods: "Dii nos quasi pilas homines habent." (*Capt. Prol.*, 22.) If any support for such a proposition be needed, the latest standard works on pathology supply, in their woodcuts, the most various microscopical illustrations, stamped all of them with the very same name—"Tubercle."

What, I think, we must conclude from a careful reading of different writers is this: that among the ancients, and even down to the time of Morton, pulmonary consumption was due to what they considered to be destruction of the lungs by ulceration. Sydenham even looked upon the close of the disease as due to what we should call now-a-days a pyæmia: "Pulmones exinde pure referti purulenta μίασματα quaquaversum in carnes dispergunt." (*a*) But with every writer, from Hippocrates to Morton, the φυμάτα ἄπεπτα, the *tubercula cruda*, were the first cause of that ulceration. Bayle, with larger experience of *post mortem* observation, allows a distinction, hardly perhaps accurate, between tubercular and ulcerous phthisis, and draws attention to the difference between miliary tubercles and miliary granulations; Laennec makes one step further, and describes the first commencement of the phthisis as extra-alveolar, leading on by some means or other to infiltration; Rokitansky sketches the sharply marked line of demarcation (*op. cit.*, vol. iv, p. 102) between "interstitial tuberculous granulation" and "tuberculous infiltration," insisting (vol. i. p. 29) on the existence of a "genuine grey tubercle granulation" which never undergoes the cheesy change, and asserting that Bayle's pulmonary granulations are vesicular tuberculous infiltrations; while Virchow (*a*) took the grey granulation to be the typical tubercle, of which cheesy metamorphosis was the subsequent characteristic. With writers of this century generally, it seems as if the word "tubercle" had become coextensive with and almost limited to "tuberculous infiltration," thus returning very nearly to its ancient meaning. The special pathology of the tubercle-granulation of the last ten or fifteen years, down to the present moment, I have attempted to sketch briefly, and I hope truly; and it needs no words of mine to show any one who reads the literature, whether of France, Germany, Italy, or England, to how many different, even histologically different, products this word "tubercle" is now applied. And I cannot but feel that, with all this uncertainty of use, even clinical facts will have no bearing till we all agree to discuss the same thing from the same standpoint—the same definition. With all humility, I think it would be well if we ceased to use the word altogether, at any rate in reference to ordinary consumption, To borrow the words of Andral in reference to the term inflammation—"created in the infancy of science, this expression, altogether metaphorical . . . is become so very vague, its interpretation is so very arbitrary, that it has really lost all value; it is like an old coin without an impression, which ought to be removed from circulation, as it only causes error and confusion." (*b*) If it must be kept, let it be for that series of clinical symptoms and pathological results, always secondary, as I believe, and always fatal, to which we do apply the name general tuberculosis; for, as regards this last affection, I am not prepared in any sense to adopt the term "granulia," first applied to it, I believe, by Empis over ten years ago, and advocated recently by Dr. Bastian. The word "granule" has at present a well-defined precise meaning in histology—a meaning which no want of a name for any particular affection ought to disturb; the vagueness of which meaning, if disturbed, would be open to the same abuses as φῦμα, tumor, tuberculum. Bayle (*op. cit.*, p. 10) truly says: "Nothing is more powerful than the influence of language. Erroneous denominations, and equivocal definitions, and false appreciations, bring in their train error, confusion, and the gravest mistakes, especially in sciences which, like medicine, are open to practical solution."

In coming to the close of this lecture, I would wish to add that, in anything I have said, I would not be supposed to detract—no assertion or supposition of mine could detract—one iota from the greatness of Laennec. The use of the word with which I have found fault did not originate with him. His attempt—and an honest one—to simplify the origin of phthisis has been carried much further, I think, than he intended. But the words in which Addison spoke of him exactly thirty years ago are to every one who reads Laennec carefully a mere statement of the truth regarding him. "We are never permitted (*c*) for a moment to imagine that we are reviewing for the first time the mere professions of an ingenious speculator or plausible theorist. We are led insensibly to the bedside of his patients; we are startled by the originality of his system; we can hardly persuade ourselves that any means so simple can accomplish so much—can overcome and reduce to order the chaotic confusion of thoracic pathology; and hesitate not, in the end, to acknowledge our unqualified wonder at

(*a*) *Works*, p. 605.

(*a*) *Cellular Pathology*, Chance's translation, page 447.

(*c*) *Guy's Hospital Rep.*, ser. ii., vol. iv., p. 1.

the triumphant confirmation of all he professed to accomplish." It may seem almost an odd thing that in these days, in which we look—and, as I take it, look rightly—for light to come from the Teutonic rather than from the Latin race, we should be turning back to the pages of these French writers, some of them still fresh in the memory of many yet living, and, digging, as it were, through the rubble that has already half concealed the real foundations, should attempt to raise, not only each for ourselves, some firmer superstructure. And yet the lesson, if in some sort our own, comes to us to-day from the Germans. Buhl sixteen years ago, and his approving critic Waldenburg later, seem to aim somewhat at the simplicity, though by no means at the theory, of Laennec. And perhaps, Sir, if simplicity and truth—the very elements of the most powerful observation—are at all to be praised, you will allow me here to pay a passing homage to one who, stepping out, as it were, from between the half-closed portals which for years had hidden him from ears that longed to hear him, inscribed, only some twelve months back, (*a*) one more conscientious record on the truthful and brilliant monument of his *Clinique Médicale*. The death in life which parted him almost altogether from the active work of his profession has become, in these last four weeks, the death indeed of one who to a great number of Englishmen had ceased to be the living possessor of a vast knowledge and a large reputation. To many of us, much his juniors, so far as he is concerned—

"Obserat umbroscs lurida porta rogos."

But Andral's name may well be added to that list, including those of Hippocrates and Aretæus, Sydenham and Morgagni, of whose works Bayle speaks (*op. cit.*, Préf. xiv.) with discerning praise as "being only expositions of facts; not, therefore, brilliant"—as compared, he means, with theories and speculations—"but having the advantage of never growing old."

ON SALICYLIC ACID.

By J. C. Ogilvie Will, M.D.,

Assistant-Surgeon to the Aberdeen Royal Infirmary.

Some months since I published in the pages of a contemporary (*Lancet*, Dec. 18, 1875) a paper on salicylic acid; since that time my experience of its effects has been greatly extended, both in hospital and in private practice, and the belief I then expressed of its usefulness has now become even stronger; I therefore desire to direct the attention of those who may be still practically unacquainted with it to some points connected with this valuable antiseptic. It is unnecessary to enter into the expements which have been practised to prove that salicylic acid is a reliable antiseptic, as that is now a matter beyond dispute; but its superiority to other antiseptics is, to say the least, at any rate so far as this country is concerned, still *sub judice*, and it is to the elucidation of this point that I at present propose to devote my remarks. The questions I shall endeavour to answer are—Wherein does the superiority of salicylic acid over other antiseptics lie? and where should it be employed? The main advantages claimed for salicylic acid, in addition to its powerful antiseptic effects—which, as I have just said, I take for granted—are its non-irritant quality, its non-volatility, and its freedom from odour. Among its lesser advantages may be classed its non-poisonous nature and the readiness with which it can be incorporated with fatty substances in the preparation of ointments. Carbolic acid is a powerful irritant, and even when used in a very dilute form it still gives rise to such a degree of irritation as to prevent epidermic formation. The irritant character of carbolic acid is universally allowed, even by its most ardent supporters, for the talented leader of the antiseptic school—Professor Lister—speaks of antiseptic suppuration, and for the purpose of preventing its occurrence he interposes a layer of prepared oiled silk—the protective as it is called—between his carbolic dressings and the wound, to preserve the wounded part from direct contact with the acid. With salicylic acid no such precautions are requisite, and that for a twofold reason, viz., that on account of its extreme antiseptic powers only a very small proportion of the acid is required, and that even when a strong preparation is employed the irritation is so slight as to be hardly worth consideration. This I have proved, not once, but very many times, and the conclusions I have myself arrived at are in perfect accord with those of Thiersch and Kolbe, who have had great experience of the effects of this antiseptic. Carbolic acid then being a most unsuitable application for a sore or wound when cicatrising action is required—some other must be sought for. Sulphate of zinc in the form of red lotion, boracic acid, and chloral hydrate all answer fairly well, and in many cases leave nothing further to be desired; but I am firmly persuaded that salicylic acid is at once both the most generally useful and productive of more favourable results than all the others put together, for under its influence the granulations become small and pointed, the discharge lessened and non-irritant, and the formation of epithelium takes place with amazing rapidity. During the past few months I have had some very striking examples of this in my wards in the Aberdeen Hospital, in cases of injury, where, as I have often pointed out to those who accompanied me during my visit, a few years ago, before the antiseptic era commenced, it would have been thought extremely bad surgery to endeavour to save the limbs, and instead of attempting to do so, immediate amputation would have been considered the correct rule of practice. In the cases referred to I simply removed such parts as were absolutely dead, and made no attempt to form flaps, the wounds being left to heal by granulation. In several cases the ends of the bones were left uncovered without the slightest untoward result, for granulations in sufficient quantity speedily sprang up from the surrounding soft parts, and useful and seemly hands resulted—for it was especially in machinery accidents in which the hand had been involved that I had recourse to this form of extreme conservative surgery. The importance of the least sacrifice of parts cannot possibly be exaggerated, when we remember that each inch of tissue left represents to the working man a certain sum of money, and this principle should ever be kept in view when dealing (surgically) with those who depend on the work of their hands for their daily bread. Some of the cases looked exceedingly unpromising for the first few days, and when I first adopted this line of practice I at times feared I had risked too much; but in no case had I ultimately reason for regret, as the results were invariably satisfactory. Salicylic acid, however, cannot of itself be credited with the successful results obtained, for carbolic acid played no small part during the course of treatment, and the comparative disuse of poultices, "the very name of which," to use the late Mr. Liston's expression, "is associated with putrefaction and nastiness," contributed not a little.

The successful issue in cases of lacerated wounds, or other open sores, does not depend on the employment of any one antiseptic throughout, but on the judicious selection of a certain substance at the proper period—at least such is my experience; and the practice I now almost invariably follow is to use an oily liniment of carbolic acid so long as marked sloughing goes on, and after the wound has become so far cleansed, a watery solution of salicylic acid is then applied. In my former remarks on salicylic acid I stated that I did not think that aqueous solutions of that substance would ever come into general use, on account of its slight solubility in water; but a more extended experience of watery preparations has convinced me that I was in error when I rather disadvised their employment. Though only sparingly soluble even in boiling water, still by adding a small proportion of borax, a lotion strong enough for any purpose can be readily

(*a*) *Documents pour servir à l'Histoire de la Glycosuria: Comptes Rendus*, 1875, tome xxv. p. 858.

obtained. The lotions I use contain respectively 5 and 10 grains of salicylic acid and 3½ and 7 grains of biborate of soda to the ounce of water. No stronger watery solution can be required than the ten-grain one, and the presence of the borax is not in the slightest degree objectionable.

The plan I generally adopt is to commence with the weaker solution, and if I find that it is not sufficiently stimulating, I gradually increase the quantity of the antiseptic, and *vice versa*. The effects of these solutions are unequalled, for the growth of the granulations proceeds at a simply marvellous rate, deep hollows becoming filled up in a few days, and simultaneously epithelial formation proceeding rapidly in such parts as are ready for that process taking place. This seems to me to be the peculiarity of salicylic acid, for in the case of all other antiseptics with which I am acquainted, it is impossible to obtain rapid development of healthy granulation tissue and epithelium at the same time. For if a solution of say carbolic acid be employed of sufficient strength to encourage granulation growth, it will certainly impede or altogether prevent that of epithelium; and again, if the strength of the antiseptic solution be such as to favour the cicatrisation of a wound, it will not be stimulating enough to further the filling up of the less advanced portions of the raw surface. In this particular, then, salicylic acid differs from all other antiseptics, for when dressings impregnated with it are employed, both indications are fulfilled, healthy granulations springing up in abundance in the deeper parts of the wound, and cicatrisation taking place at the edges. The granulations are small and extremely vascular; this is absolutely the rule, and so far as I have seen, it has no exception; so certain am I of it, that when I order salicylic acid to be applied, I feel perfectly assured that within a very short space of time the wound will present as healthy an appearance as could be desired. This is undoubtedly a strong statement; but experience has shown me that I am justified in making it, and if put to the test, I know that every member of my excellent staff of dressers would bear me out in what I have said. It has been alleged that salicylic acid gives rise to severe pain; but this I have never found, slight smarting being the nearest approach to any such sensation that I have yet heard of, though I have questioned and re-questioned many whose wounds were dressed with salicylic applications, and even when that was experienced, all the patients have assured me that it was merely momentary, and that, too, in cases where preparations containing a large percentage of the agent were employed, and even when the pure acid has been applied. As I cannot possibly account for this discrepancy of opinion, I need not dwell on it, especially as I feel convinced that if a reliable sample of the acid be employed no such symptom as severe pain will show itself.

I have as yet only alluded to watery preparations of salicylic acid, and I entered on their consideration first, not on account of their being more generally useful than the many other forms in which it may be prescribed, but because, so far as I am aware, they have been even less used than the others, and for the personal reasons already given.

Various forms of ointment may be compounded, as salicylic acid, unlike boracic acid, can be readily incorporated with fatty substances; but it would answer no useful purpose to repeat at length what has already appeared in a medical periodical regarding the different unctuous preparations of salicylic acid, so I shall simply give the formulæ for two ointments which I have found of much service. The following is perhaps the most generally applicable of any:—Salicylic acid ℥ss.—℥j., white wax ℥j., paraffin ℥ij., almond oil ℥ij.; melt and rub up in a heated mortar. This ointment, which is merely a modification of Professor Lister's boracic ointment, should be spread on strips of muslin or fine linen, and is a thoroughly trustworthy antiseptic application. The other ointment is a simple admixture of the acid and simple ointment. Wagner states that in making it it is advisable to use alcohol as a solvent, as the direct mixture of the acid and lard does not give the same good results; but as I have long been in the habit of using it in its more simple form, and have obtained most excellent results, I have not thought it necessary to change my original formula. The proportion of the acid varies with the use to which the ointment is to be put; in the cases in which I have chiefly prescribed it—viz., circumscribed eczematous affections of the head and face, I have found half-a-drachm to a drachm to the ounce wonderfully efficacious; and if any one be dubious regarding the therapeutic value of salicylic acid, let me advise him to prescribe it for a case of the kind mentioned, and I feel persuaded that the result he will obtain will at once convince him of the efficacy of the agent he has employed. On this point I cannot speak too emphatically, for I have now used it in a large number of cases, and the results were uniformly good, far surpassing any mode of treatment I have yet seen in the practice of others or in my own, so much so that I have come to regard salicylic acid as a specific in cases of eczema narium and such like affections, and I hope at a future period to give in detail a series of cases treated by salicylic ointment.

Oleaginous preparations of salicylic acid are the least elegant of all the forms in which it can be prescribed, as it is hardly at all soluble in oil; still they may be used with good effect in burns, healing action quickly taking place under this mode of treatment, putrefaction, if it be present, being arrested, and fœtor at once disappearing.

I have now endeavoured to state as briefly as possible some of the advantages of this new antiseptic, and I feel satisfied that salicylic acid only requires a fair trial to be looked on as an invaluable addition to our list of curative agents. When I first employed it I was inclined to regard the statements of those who extolled its use in the light of *omne novum pro magnifico*, but in this I was agreeably disappointed in the very first case where I prescribed it, and the conviction then arrived at has taken deeper root with each fresh case in which it has been used, and I firmly believe that ere long salicylic acid will occupy, if not the first, at least one of the foremost places, among antiseptics.

THERAPEUTICS: INCLUDING THE PHYSIOLOGICAL ACTION OF MEDICINES.

By W. Handsel Griffiths.

(*Continued from page* 379).

ACIDUM CITRICUM.

Citric acid has been used beneficially as a lotion (one or two drachms to eight ounces of water) to cancerous ulcerations. In angina, gangrenous sore-throat, &c., it is a good topical application, and it has also been found useful when applied in pruritis of the genitals.

Although citric acid was enumerated by Orfila among the irritant poisons, it has been ascertained that even in large doses it does not cause inflammation of the intestinal tract, and Broussais goes the length of affirming that citric acid is of all others that which is best supported by the stomach when that organ is inflamed. Be that as it may, it is unquestionable that lemon juice occasionally causes severe griping or diarrhœa.

Citric acid exerts a liquefying action on the blood, and hence is useful in affections characterised by excess of the fibrinous element. In scorbutic affections, in which diseased condition the coagulability of the blood is markedly impaired, although the amount of the fibrine is increased, citric acid acts beneficially, but is immeasurably inferior to lemon juice as a remedial agent. Garrod considers that citric acid is devoid of antiscorbutic properties, and that the efficacy of lemon juice in this respect is due to the potash salts which it contains.

Citric acid and lemon juice reduce the force and frequency of the pulse, and the latter is given by Dr. G. Owen Rees in doses of one or two ounces in rheumatic affections. The writer's experience of lemon juice in the treatment of rheumatic fever leads him to accredit it with the power of mitigating the severity and alleviating the pain, while it does not shorten the attack. In syphilitic

or gonorrhœal rheumatism, or in rheumatism connected with purulent discharges, lemon juice is powerless for good.

It has been stated by some writers that in hæmorrhages lemon juice or citric acid assuage thirst and counteract the tendency to loss of blood. However efficacious these agents may be in slacking thirst, the writer would pronounce them to be absolutely contraindicated where there was the slightest indication of a hæmorrhagic tendency.

Although citric acid is frequently employed for its refrigerant properties, it must not be supposed that it in any degree diminishes febrile heat.

Vogt considers that citric acid acts more on the skin and less on the alimentary canal and urinary organs than tartaric acid. The diaphoretic action of the former acid and of lemon juice is augmented when they are given in effervescence.

The administration of tablespoonful doses of lemon juice several times daily is a reputed treatment for jaundice produced by hepatic obstraction.

Mitscherlich's experiments on rabbits show that citric acid in poisonous doses exerts a powerful action on the spinal cord, causing spasm of the muscles of the back, of the respiratory muscles, and of the masseters. It also diminishes sensibility and enfeebles the action of the heart.

Citric acid is enumerated among the antidotes to alkaline and narcotic poisons.

ACIDUM GALLICUM, ACIDUM TANNICUM, GALLA.

As a topical astringent tannic acid is superior to gallic. The remarkably persistent astringency effected by the former acid on the mouth and fauces is due, not only to the coagulation of the secreted mucus but also to the constriction of the follicular orifices. Druitt recommends a solution of tannic acid in the treatment of apthous ulcers of the mouth, for moderating mercurial salivation, for reducing sponginess of the gums, and in relaxation of the uvula and pharyngeal mucous membrane. In toothache from caries, after scarifying the gums, he stops the cavity with a piece of cotton saturated with a solution consisting of twenty grains of tannic acid and five grains of mastiche in two drachms of ether.

A strong solution of tannic acid has been found useful in the treatment of conjunctivitis, acute or chronic.

Glycerine of tannic acid is recommended by Professor Ringer as an application in ozæna and nasal discharges, and in otorrhœa. A solution of five grains of tannic in an ounce of water is recommended by Druitt as an application to sore nipples, and for anal and scrotal excoriations.

In fissure of the anus Van Holsbek uses a solution of one part of tannic acid in sixteen of glycerine. Tannic acid has been employed to prevent prolapsus ani and extension of hæmorrhoids.

Several cases are recorded of prolapsus uteri having been cured by means of a tampon soaked with a saturated solution of tannic acid, and renewed daily for four or five weeks. Tannic acid injections have been beneficially employed in the treatment of chronic mucus discharge, as in gleet and leucorrhœa.

As a local application tannic acid was used by Homolle as a means of preventing the development of variolar pustules: he used a solution of one part of the acid in four of tincture of benzoin.

Tannic acid has been used in the treatment of certain skin affections, thus Alison advocates the use of an ointment of tannin in psoriasis, and the application of glycerine of tannic acid followed by poulticing has proved useful in some stages of eczema. Tannic acid topically applied in local perspirations, particularly from the armpits and feet, has been found extremely serviceable.

Given internally, in doses of one or two grains daily, tannic acid increases the appetite. On account of the small doses required it is not so likely as other astringents to disturb a delicate stomach. It is said to induce constipation but this effect rapidly subsides, indeed some authorities contend that, even in large doses, tannic acid does not constipate. It is unquestionable that in large doses it diminishes the mucous secretions of the alimentary canal, and it is hard to understand how this result can be effected unaccompanied by a certain degree of constipation. In impaired digestion of chronic diseases and in chronic diarrhœa Dr. S. C. Alison has found in tannic acid a valuable remedial agent. In all cases of chronic and wasting discharges from the bowels unaccompanied by inflammation, no other drug will be found equally efficacious. In the diarrhœa attending the abuse of alcohol I have found tannic acid to act more certainly and speedily than any other single drug, but its efficacy in this affection is infinitely enhanced when given in combination with strychnine. Gallic acid was proposed by Bayes as a remedy for pyrosis, but therapeutists are not agreed as to the class of cases most suited to such a treatment.

In irritable piles gallic acid in combination with opium is of good service.

Tannic acid has been employed as an anthelmintic, but with such poor success as to discourage its future employment for such a purpose.

As tannic acid coagulates albumen the question arises, How does it circulate in the blood? Clarus supposed that the coagulum is emulsified and rendered absorbable by fat. Buchner considers that it is converted into gallic acid, but this substance is so slightly astringent of itself that it is probable that its constitution becomes modified in its passage through the blood. It is unquestionable that tannic acid is superior to gallic acid as a topical astringent, while as a remote astringent gallic acid is the more powerful. In order to account for the astringent properties which gallic acid possesses when given internally Headland suggests that in the blood it is converted into tannic acid by the elements of grape sugar which is being continually formed during the blood-processes connected with respiration. That tannic acid is a compound of gallic acid and the elements of grape sugar is the inference to be drawn from the researches of M. Braconnot and of Strecker. When tannic acid is therefore taken into the system the elements of the grape sugar are oxidized into carbonic acid and water and gallic acid is set free. Gallic acid alone will not precipitate albumen, but a mixture of gallic acid and gum will do so. Now gum has the same constituion as sugar, and a material containing the same elements is known to be continually forming in the blood, hence gallic acid may act along with this material and so exert an astringent action. Dr. L. Earle considers that the anti-hæmorrhagic property of gallic acid is increased by combination with sulphuric acid, an opinion which an experience of several cases will not permit me to coincide with. Granthamsuccessfully gave five-grain doses of gallic acid every three hours in several cases of purpura hæmorrhagica. In internal hæmorrhages especially when of a passive nature, or when long continued, or in those in which the congestive tendency has subsided, tannic acid, although to a certain extent efficacious, is superseded by gallic acid. In the treatment of menorrhagia testimony as to the value of the latter astringent is abundant, and in hæmoptysis cures have been effected by it when all other remedies have failed. In hæmatemesis gallic acid has also proved of service, but in this latter affection I have seen better results from tannic acid, and this is to be expected on account of the topical astringency exerted by the tannin on the bleeding vessels of the stomach. In hæmaturia gallic acid has proved a reliable remedy.

In bronchial discharges tannic acid has been found to act with great benefit, but Woillez (*a*) states that its efficacy in this respect is more marked in recent than in chronic cases of excessive bronchial secretion. Tannic acid has been found to act beneficially in moderating the sweats of phthisis and other exhausting diseases; indeed, in phthisis the symptoms often appear to be palliated under the influence of this drug, and some therapeutists

(*a*) *Bull. Gen. de Thérapeutique*, Jan. 13, 1863.

suggest that it may restrain the evolution of the tubercular deposit. Of course in acute phthisis tannic acid is contra-indicated.

In whooping-cough benefit has been obtained with tannic acid, and I have known one case in which sufflation of the finely powdered acid on the fauces and pharyngeal mucous membrane was productive of very satisfactory results.

Tannic acid has been used in intermittent fever but without much benefit, it should be mentioned, however, that according to M. Sistach and others, tannate of quinine is in every respect superior to the sulphate of that alkaloid in the treatment of intermittent fever. (*a*)

Tannic acid given internally appears in the urine as gallic and pyrogallic acid.

In albuminuria depending on temporary causes gallic and tannic acids are occasionally efficacious, and Lyell states that in cases in which it is likely to do good the benefit from them will be evident within a few days. Dr. Garnier states that in albuminous anasarca consecutive to scarlatina he has found great benefit from doses of half-a-drachm or a drachm daily of tannin. (*b*) The most recent testimony in favour of the value of gallic acid in albuminuria is afforded by Dr. J. T. Jameson. (*c*) He assumes that the gallic acid is carried unchanged to the congested and inflamed capillaries of the kidneys and acts as an astringent and tonic to them, promoting their contraction, and thus arresting the exudation of the red blood corpuscles and favouring the normal secretion of urine.

In fatty or chylous urine gallic acid has proved useful, and an interesting case has been recorded by Dr. H. Bence Jones. (*d*)

Tannic acid has been recommended in diabetes, but in this affection its administration has not been productive of beneficial results.

In the after stages of gonorrhœa and in gleet injections of glycerine of tannic acid diluted with an equal quantity of olive oil or mucilage have been found to be beneficial.

Tannic acid was proposed by Kunzak as an antidote for strychnia, but it has not proved of any value in this capacity. Galls have been proposed as an antidote for tartar emetic and many alkaloids, on the ground that they form insoluble compounds with those substances, and that they constringe the mucous membranes so as to impair their absorption power. Their efficacy is at least doubtful.

Clinical Records.

ROTUNDA HOSPITAL.

Case of Ovariotomy.

By Lombe Atthill, M.D., Master of the Hospital.
Reported by Mr. H. J. Battersby, Resident Clinical Clerk.

Having previously published the particulars of two cases in which I successfully performed ovariotomy, I think it right to give those of the following one, which terminated fatally.

M. S., aged 37, unmarried, was admitted into the chronic department of the Rotunda Hospital on the 26th May last. Her history was as follows :—

Eleven years ago, when suffering from an attack of pleurisy, she noticed a tumour in the left iliac region which was very tender and painful to the touch, and which from this date extended gradually across abdomen; her size slowly increasing, her general health being good. Four years ago she came under the care of the late Dr. Duigan, of Mullingar, who diagnosed ovarian dropsy, and decided to operate, but he died before he could do so. Menstruation had been irregular of late.

In August, 1875, she was admitted into the hospital, and was tapped, twenty-one quarts of fluid being drawn off. At this time she measured upwards of 50 inches round abdomen at umbilicus.

The fluid, however, rapidly reaccumulated, and on her readmission, on the 26th of May, she measured round abdomen at umbilicus 51½ inches; ensiform cartilage to umbilicus 14 inches; symph. pubis to umbilicus 13½ inches; left ant. sup. spin. of ilium to umbilicus 17 inches; right do. to do. 16½ inches.

Fluctuation was very distinct; the front of the abdomen was dull; the flanks resonant on percussion.

On a careful consideration of the case, I decided to advise that the operation should be submitted to, as offering the only hope of prolonging life beyond a few months. The case, besides, seemed favourable, the patient being in good health, and the tumour unilocular. The risk of the operation having been clearly explained to the patient, she expressed her entire willingness to undergo it. I accordingly performed it on the 6th of June. The sac was exposed without difficulty; on sweeping sound over its peritoneal surface numerous adhesions of recent origin were broken down; the cyst was then successfully tapped with Spencer Wells' trocar, and the fluid contents evacuated without the escape of any into the cavity of the pelvis. So far all seemed most favourable; but on attempting to draw out the cyst it was found to be bound by very strong and dense adhesions, to the omentum, the transverse colon, and to the small intestines posteriorly; the breaking down of these adhesions was a most difficult and tedious matter; it was effected at last without the loss of much blood, the pedicle secured with a clamp and severed. The pedicle being very short, I cauterised it with the actual cautery freely, and securing it with a catgut ligature, removed the clamp, and threw the pedicle back into the pelvis. There had been some oozing of blood from the vesicles torn in breaking down the adhesions; this ceased. Any fluid which had collected in the pelvis was carefully sponged out, and the edges of the wound in the abdominal wall brought together with catgut ligatures, the patient swathed in a flannel roller and laid in a warm bed.

Ether and chloroform mixed was the anæsthetic employed, there was not any vomiting during the operation, which occupied about 40 minutes.

At 2.30 p.m., being two hours after the conclusion of the operation, her pulse was 88; temperature 100°.8. She was quiet and sleepy; did not suffer any pain; has had 1oz. milk and soda-water at intervals of half-an-hour; ice *ad libitum*.

3.30.—Stomach inclined to be sick—to have beef-tea instead of milk; pulse good.

6 p.m.—Pulse 110; temperature 101°; inclined to be sick; no pain. Catheter passed at 3 and 7 o'clock, and a moderate quantity of urine draw off; passed again at 10.30. Very little urine secreted.

1 a.m.—Stomach very sick, vomiting every 15 minutes; pulse 120; temp. 102°. From this time she began to sink. Stimulants were freely administered, but were instantly rejected. Enemata of beef-tea and brandy, though retained, did not appear to produce any effect; the secretion of urine was suppressed altogether; and she sank and died without pain at 6 p.m. on the 7th, being 30 hours after the operation.

Post-mortem examination made seventeen hours after death by Dr. R. Harvey.—On cutting the stitches which closed the wound there was found to be no attempt at union in it. Abdominal parietes (in front) very hæmorrhagic. The peritoneum broken away in several places to a great extent, and a large number of ecchymoses on and under its surface; in some places it is also greatly thickened, best marked low down in the abdomen (this thickening was the result of old-standing inflammation). Corresponding to the lips of the wound, the coils of small intestine and the transverse colon were firmly matted to the parietes by recent adhesions; the omentum

was thickened, highly vascular, rolled up together, and passing into a state of sphacelus. There was a good deal of bloody serum in the peritoneal cavity. Uterus, apparently somewhat elongated. Other ovary appeared healthy.

While deeply regretting the termination of this case, I have no hesitation in affirming that the operation was not only justifiable, but called for; it was impossible that life could have lasted long in a patient in whom disease had made such progress, and in whom there existed a sac of such magnitude still steadily increasing in size. The difficulties resulting from the extensive and dense posterior attachments were not and could not have been forseen, and to them the unfortunate termination of the case was without doubt due. What is to be regretted is that Dr. Duigan a unable to perform the operation when he detected the nature of the case four years ago; had he done so, the result most probably would have been different. The cause of death was evidently due to the shock, from which she never perfectly rallied.

WEDNESDAY, JUNE 21, 1876.

THE DENTAL PROFESSION.

In another column we print a letter from Mr. John Tomes, in which the main points of the discussion affecting the dental profession which has occasionally occupied a portion of our space during late weeks, are set forth temperately and clearly. Our readers will not be surprised to find that we have been in complete accord with the opinions of Mr. Tomes and the party which he represents—that part in the dental profession to whose labours the speciality entirely owes its present position. With characteristic modesty, Mr. Tomes refrains from mentioning the fact that the good work to which he alludes has been accomplished, through the energy and wisdom of himself and his coadjutors, some of whom, unfortunately, have now passed away. Twenty years ago it may be said there was no dental profession, and the vast majority of dentists were unqualified. There existed, however, a considerable minority of educated professional men pursuing the practice of the speciality, some possessing diplomas, and others, although accomplished dentists, and sometimes men of scientific attainments, without recognised qualifications. This minority after much discussion, at length united themselves into a body with the object of promoting the advancement of dentistry and rescuing it from the hands of the ignorant charlatan. With this view the Odontological Society was founded; the College of Surgeons was induced to establish a special qualification for dentists; and efficient schools for the education of dental students were organized. Since 1858 the progress of the profession has been continuous, and it has been recruited by a large number of properly educated dentists, much to the elevation of the speciality and to the benefit of the public. The Odontological Society has continued to form a bond of union between all that is good in the speciality. A scientific body in the main it has kept a due watch over the professional conduct of its members; comprising all the most eminent dentists, it has not refused its membership to any practitioner duly vouched for as an educated professional man, whether possessing a diploma or not. In this way it has tended to the elevation of the whole body of dentists, its membership being sought and valued as a stamp of honourable position, and many unqualified practitioners have doubtless been induced to practice their calling as a profession instead of as an inferior trade in the hope of meriting the membership of the society. When it is remembered how important is the union of all interests worthy to be united in furthering the progress of a profession under such circumstances, it will be seen that the Odontological Society has acted wisely in not making itself a small association to the exclusion of whatever power and energy was further available. The holders of the licence in dental surgery form the largest party in the society, and to some of them dental reform owes most; next in numbers come those without diploma, comprising many excellent dentists. Lastly, the remainder is composed of the comparative few holding full degrees in surgery. Seeing what this judicious combination of available force has accomplished with such excellent promise for the future, and how equally the credit of what has been done must be divided among all parties, it is easy to understand the resentment which has been aroused by the recent action of a small section of the qualified members of the profession, who with no real claim whatsoever to a position of leadership, have set themselves up publicly as the sole pioneers of a new departure in the path of reform, and by excluding from their ranks not merely unqualified practitioners, but also the licentiates in dental surgery, insulting by implication an honourable section of the profession, and one to which as we have said the whole body owes, to a great extent, its present respectable position.

THE VIVISECTION BATTLE.

The current number of the *Langham Magazine* contains an article on "The Vivisection Battle," written in a calm and conciliatory spirit, and worthy of the consideration of those interested in this, at the present moment, prominent question. The writer starts with the inquiry, "What have the advocates of vivisection to urge as reasons for such a practice?"—the answer to which is, we think, quite conclusive. They believe in vivisection experimentation because by this means the alleviation of human suffer-

ing is procured, and human life can be prolonged, remedical discoveries are made, and the general advancement of scientific knowledge is promoted. Every dispassionate and reasoning person will agree in the conclusion that "such avowed objects must not be rashly interfered with," for in the case of a fatal disease ravaging a country, experimentation by vivisection may enable scientific men to discover its cause and supply a remedy, or means for arresting its further progress. Cruelty to a few animals in such a case, it cannot be denied, may prove to be kindness to thousands of human beings. The opponents to this view are "total abolitionists," practical abolitionists, prohibitors of pain, and restrictionists. Among the first are those who have a total disregard as to whether experimentation may do good. "Human suffering is a matter of indifference, so far as remedial discoveries by vivisection are concerned." To be consistent, all who entertain such views, "must be stoical enough to denounce even a painless experiment on an animal to save wife, children, or relative from disease or death. If a plague break out amongst us, a disaster which may occur, rather than permit a remedy to be discovered by vivisection, they would allow thousands of their fellow-creatures to perish!" "Under any circumstances," they say, "we have no right to subject living animals to experimentation." The end to be obtained can under no circumstances, it is stated, justify the means. Careful observers of modern progress and logically minded persons will admit that such a position is totally untenable. The total abolitionists, also, in their zeal, misrepresent facts connected with this subject. "It is urged that man has no right to take away or tamper with animal life. It is said to be an abuse of man's power to subject animals to experimentation and curtail their lives by vivisection. Life, in all its profound mysteriousness, having been given by the Creator to animals, is considered too sacred to permit of man's interference with it. Being unable to replace the life which has been sacrificed, man in sacrificing it oversteps the limit of power and dominion with which he has been entrusted. To abbreviate the span of existence allotted to animals is an unjustifiable interference with their rights, and an offence against the laws of God." A careful consideration of such arguments must convince any one, as it has the writer of the article, that they are "either maudlin sentimentality or twaddle;" for is not animal life hourly sacrificed for human food, clothing, and many other purposes? Do we not out of compassionate feelings destroy animal life in aged animals? Where then, is the sacredness of animal life as represented? As regards the unqualified statement that an abbreviation of life in animals is an offence against the law of God, it may be asked, Who ordered the law of nature? By the decree of a wise Providence, many species of animals exist only by the destruction of certain animals of other species. Is then the whole order of nature wrong? Has Providence not only initiated, but perpetuated error in its arrangements with regard to nature? This, of course, will not be admitted, and at once the argument advanced resolves itself into an absurdity. Then what becomes of the proposition that man has no right to take away life in animals? It tumbles to pieces, and in its fall necessarily injures the claims of a righteous cause. It is incumbent upon us, no doubt, to protect all creatures from cruelty; but, we ask, do those who advocate abolition of vivisection, and would prohibit the infliction of pain on animals, carry their condemnation into practice? We fear not, or they would not be found joining in cruel sports, and the unnecessary mutilation of animals, as the cropping of the tails of horses and cattle, the ears and tails of dogs, and the still more barbarous practice of entirely shaving off the coats of dogs, the mutilation of lambs and pigs, the trapping and subjecting to a cruel and lingering death various animals and birds supposed to rob orchards and gardens, in short, of those "who needlessly set foot upon a worm." One other point, and we have done, and this we would briefly notice, because it has given rise to misconceptions in quarters little suspected, during this discussion on vivisection—it is in reference to hospitals. It has been urged that even the Hospital Sunday contributions should be "withheld from institutions in which the dissection of live animals is practised." It is also urged that "some portion of the money collected may be applied to the purchase of the unfortunate animals condemned to undergo these experiments, or to the building of premises for experimental purposes." This appeal is cruelly unjust, for several reasons. In the first place, the funds of medical schools are entirely distinct from those of the hospital. Medical schools and medical teachers are paid by the fees of the students, and not by the hospital: if there were no hospitals, experimental physiology would in all probability be taught for the sake of gaining scientific knowledge. In some instances the teachers of the medical schools contribute largely towards the maintenance of the hospitals and the relief of suffering humanity. In the next place, the contributions of the Metropolitan Hospital Sunday Fund are divided solely amongst hospitals already in existence, unendowed charities; those in course of construction, and the large endowed hospitals—Bartholomew's, Guy's, and St. Thomas's, the University of Edinburgh, Owens College, Manchester, and the Brown Institution, over which Dr. Klein presides, have no share whatever in the distribution.

Notes on Current Topics.

Lord Elcho on Pure Air and Water.

ALTHOUGH Lord Elcho's commendable efforts to bring about a better state of things for the metropolis, secure a pure water supply, supersede the chaos of vestries and divided authorities, apparently perpetuated to increase our sanitary evils, has once more been unattended with the success it deserves, we do hope he will not be disheartened by his defeat, but rather stimulated to persevere to the bitter end. It is certainly very derogatory to the largest city in the world, as well as impolitic, to have such necessaries of life, as the water we drink, the air we breathe, gas, and other equally important matters, in the hands of those whose chief object is to make money, but not to preserve the health or prolong life, or inquire in what way sewage and water pipes conduce to spread fevers. Mr. Lowe, in the course of the debate, drew a vivid picture of divided authority in London, and its consequences. He said:—"Take the case of gas. There

was not a town in England that would submit to be treated as London was treated in its gas supply, the quality of which was deteriorating, whilst its price was increasing, the chief reason of which is a barefaced and gross monopoly on the part of a number of chartered companies. Then take the case of water, What was one of the greatest insult which one human being could offer another? If one man compelled his neighbour to drink his sewage, the latter was put almost as low as he could be put. Yet this was precisely the position of most of the inhabitants of London. He enjoyed the blessings of a water supply from the Chelsea Water Company, and hardly a newspaper he took up without reading about the large proportion of animal organisms it contained. This meant that all the towns on the banks of the Thames, above the metropolis, were discharging their sewage into the river, and that the people of London were forced to drink the water so defiled. The people of the first city in the world were thereby subjected to an insult which no decent master would offer to his slave." This state of things, Mr. Lowe believed, would soon be terminated if London enjoyed a "Municipal Council" of the best class of men, who would devote their attention to the noble task of securing and regulating the daily life of so large a portion as 3,600,000 of the human race. In this view of the question we are quite agreed.

Medical Females in Russia.

THE thin end of the wedge towards legalising women for the practice of medicine in Russia, was inserted last week, when for the first time the degree of M.D. was conferred upon a lady. The fair possessor of the doctorate is Madame Roudneff, who entered the medical academy as a free scholar in 1868, and, after having completed her course of study, left the establishment with the gold medal, and soon afterwards went up for her doctor's degree. Referring to the subject, the correspondent of the *Standard* newspaper says it is generally allowed that Madame Roudneff defended her dissertation with remarkable ability, and she was highly complimented by all the members of the faculty who were present.

The Treatment by Injection of Ammonia for Snake Bites.

SOME experiments have been lately made by a subcommittee of the Medical Society at Melbourne, with a view of testing Professor Halford's remedy for snake bites. A number of snakes were procured, and were made to bite a capsule covered with oiled muslin, the poison deposited in the capsule being carefully weighed by Dr. Kirkland, of the University. An accurately weighed dose was then immediately injected with the hypodermic syringe under the skin of the dog to be experimented on, and time and effects duly noted. The ammonia used was liquor ammoniæ. As the attention of the committee was particularly directed to the intravenous injection of ammonia, this remedy was employed in thirty-one cases, in four of which it was injected by Professor Halford. The committee reported that it could not be said that the ammonia treatment was in any way beneficial. All the four dogs experimented on by Professor Halford himself, died, as did the other dogs in the hands of the committee. At a meeting of the Medical Society, Professor Halford said that he had no doubt whatever that the results of the experiments were given correctly in the report. It seemed to him, however, that it was the mode in which the dogs mentioned in the report had been poisoned, which caused the difference between the results arrived at and those he found when he made similar experiments before.

International Science.

ON Tuesday week Professor Donders gave an interesting demonstration at Moorfields on the "Metrical System of Numbering Spectacles," and on "Snellen's Photometer." The learned lecturer said the only difficulty was to fix unity, some wishing it to be two hundred and forty centimetres, some three hundred, whilst he preferred four hundred. He explained that by the adoption of uniformity and from *unity*, the operation of correcting ametropia by means of single or combined lenses would be greatly facilitated. Whether the metrical system will in this country supersede the old method of numbering remains to be seen. It must be some time before it can be brought into use, as opticians will scarcely care to take it up, since it involves time and trouble, as well as expense. The photometer was shown to be simple in its application, and thoroughly efficient for the determination of the relative value of lenses. The learned Professor was even more at home at South Kensington last week, where he exhibited and explained some of the numerous ingeniously contrived scientific instruments that enrich the collection under the heading of Ophthalmological Apparatus. He commenced by giving a short account of the movements of the eyes, and how this is effected by the muscles; he then went on to describe an instrument designed by him, which he called "a controller." This consists of a bent wooden rod, with a mouth-piece set on one end, and on the other a coloured strip, moving on an axis, passing through the centre of movement of the eye. After fixation in the direction of the axis, the eye being directed upon the coloured strip, the after-picture is seen in the prolongation of the strip (the law of Listing), and in whatever way the line of fixation reaches the extremity (the law of Donders). A series of experiments made with lateral inclination of the head shows how far the associated rotary motion interferes with the law of Listing. This "controller" of the laws of Donders and Listing has not previously been described. He then exhibited an ingenious instrument, the Cycloscope, intended to show the direction of the meridians, the great circles, the direction of the circles, and the parallel circles of the field of vision. The value and bearing of such investigations will be found and fully explained in Helmholtz's "Physiological Optics." The Horopteroscope, Donders explained, was an instrument designed for the determination of the line-horopter-plane at different degrees of inclination of the plane of fixation and at different degrees of convergence. By this contrivance we find the position for close work with the hands, and which, according to the inventor, has in course of time determined the angle between meridians of apparent equal direction; whilst the Isoscope enables us to determine the angle between the meridians of apparent vertical and horizontal directions at any degree of convergence, separately or simultaneously, and investigate at

the same moment how lines or objects in the field of vision influence these angles. By another instrument equally ingenious, the Photostereoscope, we are enabled to determine the relative value of the second eye for binocular vision; this has been constructed by Donders on the principle of Hering; whilst the Noematachometer accurately registers two sounds, two lights, or a light and a sound (by sliding prism rods and frames), the difference in time between two impressions, and to a perfect certainty. The priority of two impressions can also be determined by this instrument. Donders concluded by describing his apparatus for observing and registering physical processes; the method of testing the length of the duration of the action of willing and producing a result. A vowel sound, for instance, is called out by some person, and a second person has immediately on hearing that to call out the same sound. The processes involved are those of hearing the sound, arranging the larynx to repeat it, and making the muscular effort to reproduce it. It was thus seen that when it is known beforehand what vowel is to be sounded the time occupied can be measured with accuracy.

The Anti-Vaccination Craze.

The Bishop of Manchester being solicited to attend an anti-vaccination meeting, has administered a rebuke to the promoters, which is all the more severe, because it is consistent with common sense and at variance with the mistaken feelings of these fanatics. "You," said the Bishop, "are prepared to argue the vaccination question on the simple basis of ascertained facts. According to the preponderance of these, one way or the other so let the conclusion be. The vaccination question has become one of primary sanitary importance, if the facts alleged can be substantiated. They do not, however, prove to my mind that vaccination is mischievous—indeed, its benefits seem to me to be established by an overwhelming mass of evidence —but simply that vaccine lymph is often poisoned; in which case, of course, it must be mischievous, and may be fatally mischievous. My opinion is not changed upon the subject of the prophylactic efforts of vaccination when properly administered, nor as regards the necessity of the proper conditions being observed in the administration—namely, that the lymph is procured from a healthy subject, and that the child is in a proper state to receive it into its system. I should, however, be unfeignedly glad to see the question once for all disposed of in a full and fair discussion between competent representatives of the opposing schools."

The Determination of Sex.

In an article which appears in the *Philadelphia Medical Reporter*, of May 20, Dr. Capshaw refers to the experience a French stock raiser, M. Thury, had acquired of controlling the sex of colts and calfs, whose dams were subject to his management. His theory was that the impress of sex was made at the moment of fertile conjugation, and that it took form from the parent which happened to be possessed of the greater amount of erotic humour at the time of sexual contact. He also observed that the erotic heat of the females was highest during the first few days of its advent, after which it gradually abated in them to aversion, before the males gave up the pursuit.

In pursuance of this theory, when he desired a female product, he only admitted the males to his mares and cows at the early stage of the erotic fever. On the contrary, if a male product was desired, he kept the sexes apart till the females had passed the climax of excitement and were about to reach the point of aversion, before the males were permitted to conjugate with them. By carefully watching and managing, in the manner described, he confidently asserted that he could foretell the sex of each forthcoming young before it was dropped.

In applying this theory to the human subject, Dr. Capshaw states that he has watched all cases in which male children had been born at the natural period after the marriage day, and had found on inquiry in such cases that the mother had just passed her menstrual period at the time of marriage. A more forcible proof of the truth of the theory—if it be true—is that in nearly every instance in which a woman complains of having gone beyond her time the child is a female, because conception has taken place immediately *before* menstruation, though the mother had made her calculation from the previous period. The same effect takes place—says the author—in those cases in which persons abstain from intercourse for ten or twelve days after menstruation in the hope of having no children. They trespass upon the succeeding erotic term of the wife, and the almost invariable result is a girl.

Sanitation in Dublin.

The prospects of sanitation in Dublin, are—we are gratified to observe — promising. The Sanitary Association has done a great deal towards stimulating the Public Health Committee of the Corporation and the laws of nature have aided them by causing a couple of dilapidated houses—types of many hundred disease dens which exist under corporate patronage—to fall and thus bring into disrepute the City Engineer, whose duty it is to look after such dwellings.

To Sir Arthur Guinness and his brother Mr. Edward Cecil Guinness is due the greatest honour of the sanitary revival, upon which we trust we are not premature in congratulating the city of Dublin. To their liberality and energy the citizens owe the opening of St. Stephen's Green to the public and its improvement, which not even the antagonism of a selfish and retrogressive party in the Corporation will now prevent; to them we owe the principal share in starting the Artisans' Dwellings Company which has just held its preliminary meeting, and which will take from the incompetent hands of the municipal body the application of the Artisans' Dwellings Act to the city. To Sir Arthur Guinness also, is mainly due the investigation of the city finances by the Select Committee of the House of Commons, which inquiry has already relieved the citizens of a defaulting treasurer, and which, without doubt, will yet bear important fruit in the way of further reform. If the main drainage of the city and the cleansing of the Liffey were, as they are likely to be, snatched from the hands of the Corporation by the citizens, as the building of bridges has been, there would be a reasonable hope of these urgent improvements being carried out.

It is too bad that the taxpayers should be obliged to undertake such works themselves, and that the generosity of individuals should be called upon to execute works

which it is the function of the Corporation to deal with, but—if it be impossible to relieve the community of the burthen of its civic representatives, the next most desirable consummation would be that they should be left no higher function than the eternal squabbling over politico-religious controversies and the perpetration of petty jobs which duties they now discharge with so much efficiency and *gusto*.

Poisonous Disinfectants.

A CHILD has been accidentally poisoned by drinking carbolic acid. The mother said that the landlady bought two penny-worth of carbolic acid at an oilshop, which she put in a milk can, and placed it in the passage as a disinfectant, one of her children being ill with fever. Subsequently deceased took up the can, and drank the contents, and was found lying in the passage nearly choked. The child was taken to the Great Northern Hospital, were it died two hours after.

Pollution of Rivers.

MR. SCLATER-BOOTH, in moving for leave to bring in his promised Bill for Preventing the Pollution of Rivers, described it as an initiatory Bill entirely removed from a party character. A Royal Commission on the Pollution of Rivers had been sitting for many years, and last year the final volume of their report was published. The time had therefore arrived when something ought to be done. Three or four Bills had been presented to Parliament, and, although they had from various causes failed to pass into law, there had never been any dispute as to the necessity for legislation on this subject. The obstacles were, however very great, and the alarm of the manufacturers had been so difficult to deal with, that successive Bills had been brought in and withdrawn. Last year there was a reasonable opportunity of passing the Bill brought into the other House by Lord Salisbury if it had not been for the late period of the Session at which the measure came down to that House, and the necessity of proceeding with other measures. A Bill for preventing the pollution of rivers, however, formed no part of the Government programme of the Session, and advisedly so. But several members had within the last few months urged him to bring forward a measure on the subject, and he had reason to believe that a Bill, somewhat of the character of that which had passed the House of Lords last year, would be generally acceptable. The present Bill, he might add, proposed to enact generally that rivers were to be kept from pollution, and that their pollution in various ways was to be a statutable offence. In the first place it was intended to prohibit the casting of noxious refuse, whether manufacturing or mining, into rivers so as to pollute the stream or to impede navigation. The second part of the Bill related to the mode of dealing with the sewage of towns, and it was proposed that the pollution of rivers by that means should also be made a statutable offence, but that ample time should be given within which proceedings should be instituted, as well as ample time to the authorities within which to construct necessary works. There was nothing in that portion of the Bill more stringent than had for many years been the law with reference to the streams which flowed into the Thames and the Lea, in both of which cases the arbitrary power of preventing the throwing of noxious sewage into those streams had been prohibited. The manufacturing and mineral pollution of rivers stood in a very different position, but it was not deemed expedient in such a Bill as the present to make any exceptions from the general obligations of the law, but it was proposed in the case of manufacturing and mineral pollution not only that ample time should be given, but that industrial interests should be duly considered, and that no prosecution should be instituted except by the public sanitary authority, with the sanction of the Local Government Board. Up to that point the Bill stood very much in the position of that which had passed through the House of Lords last year, but there were two or three important additional provisions. It was proposed to constitute a Conservancy Board which would take in hand the functions of carrying out the necessary works, and that the sanitary authorities might be permitted to pass by-laws and regulations, and give facilities for the use of their sewers. The prosecutions under the Bill were, he might add, to be carried on before the county court judges, as under the Bill of last year. Other points of importance would remain which might be dealt with in future measures, but he hoped the present Bill, as an initiative measure, would in future secure our rivers from pollution. He moved for leave to bring in a Bill to make further provision for the better prevention of the pollution of rivers.

If any proof were wanting to show the urgent necessity for immediate legislation, we might refer members of Parliament to Dr. A. Watson's report for the urban districts of Penistone and Thurlstone. He writes:—"The river Don is at present the receptacle for all the sewage and liquid refuse of the district. For a considerable distance, from the reservoir at Dunsford, it is a beautiful stream of water; but as the ochre water from Crowedge comes in, impurity commences, and by the time it reaches Penstone Bridge, it may be said to be converted into an open drain. The river is liable to floods all the year round, and on the subsidence of these, the banks are more or less covered with the slimy refuse of drainage. As it reaches Spring Vale, it again becomes a source of danger from a sanitary point of view. The Cubley Brook is here the watercourse from which danger is to be apprehended. This little stream receives the refuse and drainage from the brewery at Cubley, and immediately after it receives all the drainage of every kind from Penistone Green. It now becomes a stinking ditch, and for six months of the year it is a standing nuisance to the unfortunate people who live beside it. Many of the houses are close to its edge, and persons living in them suffer from headache, sickness, and general *malaise*. But this is not all: a few yards further down this drain is dammed up to form a reserve for the works of Messrs. Carmell and Co., and it is the only available source of drinking water for a large number of people in Spring Vale. It follows from this that at any moment a single case of typhoid fever at Penstone Green may affect the whole of Spring Vale, a large and increasing suburb."

Collapse of the Sham Diploma Trade.

A CORRESPONDENT of the *Students' Journal* says that there is now no one in London who sells foreign diplomas

and degrees, as "Professor" Sturman who formerly held "the official position of secretary to several foreign universities" (these are his own words) has entered on another line of business. On passing his house a few days ago, I found that it was no longer designated "Packington College," and that in place of "Dr. Sturman" on the door-plate, was simply engraved "Sturman." In the parlour window were exposed three fowling-pieces, and a card relating to Eley's ammunition. A card was also exposed in the window, on which was printed "Sturman, gunmaker, established 1820."

The Queen's University Graduates' Association.

We are glad to learn that the Queen's University Graduates' Association which was established last year under the presidency of Mr. MacCormac, of St. Thomas's Hospital, promises to become an active and useful body. The association had their annual dinner on the 31st ult., at the St. James's Restaurant, Piccadilly, after which the prospects and work of the society were discussed, and the officers elected for the ensuing year. Among the members are a great number of medical men in practice in or near London, besides barristers, clergymen, members of the Civil Service, men of letters, and others.

An Administrator of Sanitation.

At the meeting of the guardians of the Athy Union last week, a member of that enlightened body is reported to have spoken as follows: "I have heard nothing at this board for the last twelve months but sanitary business—an eternal ding of 'pumps, pumps, pumps, sewers, sewers, sewers, nuisances, nuisances, nuisances,' until it has become *perfectly disgusting!* How on earth does it happen that the sewage of the town *has been running into the river for the last fifty years*, and has only now been discovered to be a nuisance?" This gentleman accurately expresses the views of a number—if not a majority, at least a very large minority—of the Poor-law guardians of Ireland. It is to this class of persons that the Government of the day most unfortunately entrusted the execution of Irish sanitary law, and as any Poor-law medical officer in Ireland could have foretold, the Public Health (Ireland) Act has proved to be a miserable failure. The Irish Local Government Board complacently congratulates itself on its sanitary performances, but those who choose to tell the truth say, that at the present rate of progress in health reform in Ireland it will be at least a quarter of a century before a really better state of affairs is established throughout the country. In a few sanitary districts—perhaps fifty out of the thousand and odd—the medical officers have gone into the work *con amore*, and without being paid for it, and at the cost of much unpopularity, have insisted on forcing the matter on the attention of the guardians. Very frequently their representations have been utterly and contemptuously disregarded, and in not one union, as far as we know has a well-intentioned energetic effort been made by the guardians. It was not to have been expected, on the principle of "Set a thief to catch a thief." Parliament has employed for the abolition of cess-pools and dung-heaps and the shutting up of disease-dens persons who are often themselves the proprietors of cess-pools, dung-heaps, and disease-dens, and who have been brought up from childhood in the familiar contemplation of such objects. Of course, they are not likely to keep the sanitary officer awake and active, and the sanitary officer is not likely to offend his patrons and give himself trouble and annoyance, when he is only paid a nominal salary of £5 or £10, as a hint that he is not expected to bother himself or the guardians. The noteworthy part of the system is, that the Irish Local Government Board are the body who first gave this hint to the guardians and officers, for they ordered that nothing but a sham salary should be paid, and from that day to this they have looked on placidly and complacently, leaving the machine to work itself if it could, but not making the least effort to quicken its speed or give it fuel.

Visitation of the Irish College of Surgeons' Examination.

A debate, which if it had no other advantage, lent animation and interest to the deliberations of the General Medical Council, arose in reference to the reply of the Irish College of Surgeons to the censure upon its examination expressed by the visitors of the Medical Council, Dr. Aquilla Smith and Dr. River, upon which document Dr. Smith claimed a right of personal explanation. The reply was published in the Medical Press and Circular of the 6th of September, 1874, and with it was published our comments upon the matter which Dr. Smith quoted at length in evidence of the justice of the censure passed by the visitors. He now claimed the permission of the Council to explain that the reply misrepresented the views of the visitors by a suppression of parts of sentences which altered the sense. The article in the Medical Press and Circular, Dr. Smith observed, said, "It is quite true that the Council had had under consideration for nearly three years a scheme for a new examination, which would have removed all the objections of the visitors" The visitors had admitted that they had heard that such a thing was in contemplation. The article then continued: "These good intentions, however, could not have the effect of modifying the verdict of the visitors upon the system upon which they were ordered to report; and though the contemplated action of the Council should be prominently alluded to, yet the duty of the visitors was clearly to expose and comment upon the faults of the system which was in action before them." This the visitors did honestly. That fact is, that the Council (of the College of Surgeons) had weakly permitted itself to be influenced by the violent opposition to improvement which emanated from the Dublin grinders, and from some of the examiners, and an active minority of its own members, and had conceded, in deference to this opposition, a further continuance of the old system; and that system was, at the time of the visitors' report, practically, if not legally, the law of the College. The visitors, the Medical Council, and the Medical Press may be congratulated upon the immediate outcome of the strong censure to which the College has been subjected; and the Council of the College deserves credit for having shown a praiseworthy readiness to acquiesce in the views of the visitors."

The speaker tells the truth in an unpleasant phrase,

but it is the truth nevertheless, and the Irish College of Surgeons deserve the blow which Dr. Smith has dealt it. It is a compliment to the visitors that the College has greatly improved its examinations since their report was made public, and if the much needed reforms of system which have been carried out be passed, there will be no cause for an expression of disapproval on the part of the next visitors.

While thus approving of Dr. Smith's defence we consider that he was permitted by the President to step altogether outside the limits of a personal explanation and to make accusations and raise issues, which it was most unjust to forbid Mr. Macnamara to reply to. Serious charges capable of denial, and, if an irregularity of debate had been already permitted, a further latitude ought to have been given Mr. Macnamara to refute them.

The Evils of Intemperance.

CARDINAL MANNING speaking last week in support of Sir Wilfred Lawson's "Permissive Bill," said that in his opinion the publicans' business came under the law passed against "noxious trades," and ought to be proceeded against as a nuisance. It is certainly a trade directed against the health and morals of the community at large; and we gather from the debate in the House last week, that the country is thoroughly convinced that the facilities for drinking ought in some way to be curtailed, but in what way this can be done, so as not to interfere with vested interests, the large brewing firms, &c., and where Parliamentary influence, is just now paramount to every other consideration, it is difficult to say. It seems, however, as Mr. Bright observed, "that the Government have retrograded with respect to the question, inasmuch as they had repealed one of the most beneficial provisions of the late Government; with respect to the hours at which public-houses should be closed." The question is one, in which all who seek to promote the happiness of mankind must take a deep interest. The broad facts, which meet us face to face, are sufficient to convince every reasoning person, of the great and growing evils of drunkenness. The crimes, the poverty, the misery, and the damage to health and life, that follow in the train of intoxicating drinks, surely need no further enforcing on the attention of the Legislature. There is one phase of this important question, and which is rarely allowed to enter into our discussions; it is, as to whether intemperance is a principle factor in the production of insanity. Members of the profession who have had considerable opportunities for throwing light upon this point, assert that intemperance is a leading cause of insanity, brings in its course destruction of mind as well as the body; while others hold to a contrary opinion. Dr. Dolan, the medical officer of the Wakefield Asylum, in a late report to the Halifax magistrates observes that while insanity appears to be on the increase, the cause of this increase is somewhat obscure, for in the Halifax Asylum only two patients were classified as suffering from insanity, result of the abuse of alcohol. He further states, that, of the 200 insane who have come directly under his notice, in only five cases can the cause be traced to intemperance; but as an indirect agent, that is acting through parents, &c., he is unable to give an opinion; though it must be confessed that habits of intemperance may, in many ways, be a great indirect factor in the causation of insanity. We agree with Dr. Dolan's general remarks on this question, that although "much of the increase of insanity has been assigned to the feverish excitement of the age, to the high pressure put on all in the struggle for existence, the race of wealth, ambition, and all the other indications of a fast life," that these causes alone will not account for the great increase of insanity.

The Vivisection Bill.

THE followiug series of resolutions have been adopted by the Council of the Royal College of Surgeons in Ireland:—

1. "That the Council of the Royal College of Surgeons in Ireland, while deeply impressed with the importance of avoiding the infliction of needless pain in the performance of experiments on living animals, regard experimentation as indispensable for the advancement of physiological knowledge."
2. "That the Council is aware that the Report of the Royal Commission to investigate the subject of experimentation on live animals, has not brought to light one single case of abuse in any of the English or Irish Medical Schools, such as would justify exceptional legislation on the subject."
3. "That the Council of the Royal College of Surgeons in Ireland views with regret the restrictions placed upon Physiologists by the Bill intituled "An Act to prevent cruel experiments on Animals," now before Parliament, and earnestly recommends to the favourable consideration of the Government the modifications of the Bill suggested by the Medical Council."

Accident to Dr. Farre.

DR. FARRE, while dressing in order to dine with his brother, had his attention drawn to a confused noise outside the house, and opening the window at the back of his residence in Hereford Street, Mayfair, he overbalanced himself and fell into the area below, a fall of thirty feet. His professional friends, Mr. Prescott Hewitt, Sir James Paget, and Mr. Pollock were immediately called in, and upon investigation found that Dr. Farre had sustained a compound fracture of the right ankle, and a few bruises of no import. Dr. Farre is doing well; but it will be some weeks before he will be able to resume the active duties of his profession.

Poor-law Medical Administration

A DEPUTATION from the Council of the Poor-law Medical Officers' Association waited on the President of the Local Government Board, to press upon him the advisability of an amendment of the Superannuation Act, and the desirability of requiring guardians to find all medicines. Mr. Sclater-Booth in replying, said that as Poor-law medical officers did not devote their whole time to their duties, and were employed by local authorities, they were in a different position to that held by civil servants of the Crown, especially as regards pension allowances. Government would not be likely to charge the rates with the superannuation of parochial medical officers, In those rare occasions where a man's service had been continuous, he would encourage the granting of pensions. Regarding the establishment of dispensaries,

there was no reason why the system should be extended to populous places throughout the country. There was, however, an impression abroad that medical relief was too freely given at present. The deputation thanked Mr. Booth, and then withdrew.

The Plague.

VERY many contradictory reports have appeared in the papers with regard to the plague. One day it is asserted that it is spreading, and the next this is positively denied: but, from the report just issued from the Medical Officer of the Privy Council, we gather from a note appended by Mr. Simon that, "at the present time, the infection of the disease is in Bagdad; and, being there, it may find considerable facilities for diffusing itself to other places; and though, in view of the experience of the last two centuries, we need not anticipate as probable that, if plague should extend considerably in the Levant, it must therefore necessarily extend to any part of Western Europe. and at least to cause much derangement of traffic."

The Gratuitous Services of the Profession.

THE President of the Sacramento Medical Society, in his address published in the *Pacific Medical and Surgical Journal*, discussing the claims of the profession to public consideration, says:—"There is no profession, by the members of which eleemosynary services are more liberally dispensed than the medical; but justice requires that some limits should be placed to the performance of such good offices. Poverty, professional brotherhood, and certain public duties above referred to, should always be recognized as presenting valid claims for gratuitous services; but neither institutions endowed by the public or by rich individuals; societies for mutual benefit, for the insurance of lives, or for analagous purposes; nor any profession or occupation, can be admitted to possess such privilege. Nor can it be justly expected of physicans to furnish certificates of inability to serve on juries, to perform militia duty or to testify to the state of health of persons wishing to insure their lives, obtain pensions or the like, without a pecuniary acknowledgment. But to individuals in indigent circumstances, such professional services should always be given."

Outbreak of Measles amongst Emigrants.

AN outbreak of measles has occurred at Liverpool amongst the Russian emigrants *en route* for Canada. On their arrival in Liverpool, from Hull, they were in such a state that they had to be at once removed to the workhouse, where they were kept at the request of the steamship agents—the Dominion Shipping Company. Not being paupers, the workhouse authorities were not bound to relieve them, but rather than risk the spreading of the disease by allowing them to locate in the town, they consented. It is intended, however, to ask the Local Government Board that an inquiry should be instituted into the circumstances of the sending of the emigrants from Hull, as it is said their condition must have been evident to the medical man who passed them on a clean bill of health from that place.

The Effects of Lightning.

WE learn from *Nature* a remarkable instance of the attractive power of metals and living beings for lightning. It appears that on June 7th a violent thunderstorm occurred at Valbonne, a large plain near Lyons, on which soldiers were encamped, and the only objects struck were huts full of soldiers with their arms piled. The occurrence furnishes a marked illustration of the "power of points." Three tents were struck in succession; the occupants of the first were absent at the moment, and the effects were relatively slight, producing only the breaking of stones and dispersing clouds of dust. In the second instance a soldier who was standing erect in front of one of the tents was struck, but the tent being near an electric telegraph, the lightning escaped by it, fired the arris, and broke a dozen poles. This circumstance may suggest an easy method of protecting an encampment. The third flash struck a number of tents placed in a zig-zag line, doing much damage, several of the occupants being either killed or wounded. In one tent three men were killed and seven wounded. All of them were either touched in both legs or on the right side, except one, who was wounded in the right eye. In another tent four men were wounded, all of them in both legs or in the left one. In other instances men were turned [round in or heaved out of their beds, made of iron, and the sentry standing in front remained unhurt. In one tent a man who was lying between two others who were killed escaped injury. The uniforms of the soldiers were perforated, and exhibited small spots, one, four centimetres in diameter, entirely sulphurised. A chemical analysis will be made of this part of the uniforms, and the result communicated to the Academy of Sciences.

Ulceration of the Frænum Linguæ in Whooping-cough.

SOME discussion has been raised by Dr. Morton's paper on the above subject, read at the Harveian Society. The coincidence of ulceration in this particular position with pertussis is not new, though English authors have not referred to it, except casually, in association with stomatitis. This ulceration has been described in both French and German literature, more especially by Bouchut in his works on diseases of children and new-born infants, though what relationship it has to pertussis, or why it exists at all in that position, is not decided. To Dr. Morton, however, is due the credit of collecting statistics of the percentage of cases of whooping-cough in which it occurs, and also of bringing it prominently forward for the consideration of English observers.

The Ethics of Adulteration.

IN giving judgment in the milk of sulphur case to which we referred last week, the judge gave expression to an opinion which fairly and honestly conveys the merits of his judgment:—"Can it be just and right," he said, "that the practice advocated by the defendant of selling the impure article under the same name and at the same price as the pure should be allowed to continue? I think not, and it ought to be put a stop to. A person who sells as milk of sulphur an article which contained only one-third part

of pure sulphur and two-thirds of plaster of Paris does sell to the prejudice of the purchaser a drug which is not of the nature, substance, and quality demanded by such purchaser. *If, as is stated, there are many persons who prefer the impure article on the ground that it is more easily dissolved in water, by all means let them have it, but let them demand it* eo nomine, *and let it be sold with a distinctive label, that it 'contains sulphate of lime.'* There can be no hardship in this to the druggist, but without such label I think it ought to be sold as milk of sulphur. I should be very glad if the trade generally would have consented to adopt such a distinctive label."

The learned judge thus reiterates the opinion which we have always expressed, and which indeed, is the only one consonant with honesty and justice; but we have no expectation that the druggists will take his advice, for they knew very well that the public does not want to buy sulphur and plaster of Paris, and will refuse to have it if it be properly labelled.

This judgment has created a stir amongst the chemists and druggists, whose special organ is at its wit's end to escape the logical dilemma upon which the judge's decision has impaled them. It endeavours to show that the sale of sulphur and plaster of Paris is quite orthodox, because that compound was contained in a Pharmacopœia of the year 1746, an argument which illustrates the straits to which the trade are put to defend the adulteration. The article set down in the Pharmacopœia of 150 years ago is, says the *Chemist and Druggist*, "a combination of sulphur and lime. *We are not called upon to explain why this combination has acquired such favour; the fact properly supported ought to suffice to settle the case.*" We venture to supply the explanation of the fact which our contemporary is "not called upon to" give. A hundred and fifty years ago the formula for precipitation of sulphur from a lime solution by means of sulphuric acid got into the Pharmacopœia because at that time the compilers were ignorant of the use of hydrochloric acid for such a purpose, and of the fact that sulphur precipitated by it contained no plaster of Paris. As soon as the discovery was made the formula was amended: but the druggists found it more profitable to adhere to the obsolete formula, which paid them much better than the new one. The *Chemist and Druggist* says that "to talk of fraud in this connection is puerile." We emulate puerility in this matter, and assert that the sale of "milk of sulphur" without notice to the customer of its nature is a deliberate fraud, and we do our contemporary the justice to believe that it is not without serious apprehension that the transaction may be properly described as such. Trade money interests die hard, and it is astonishing how much killing the "citrate of magnesia" and "milk of sulphur" adulterations have taken. It is to be expected that individuals who are making money by the traffic will resist and struggle, but it is melancholy to observe that councils and journals which have custody of the morality of the pharmaceutists are not above protecting these abuses and dishonesties for the benefit of their constituents.

Dr. John Wickham Legg, Casualty Physician and Demonstrator of Morbid Anatomy at St. Bartholomew's Hospital, was elected a Fellow of the Royal College of Physicians, London, on Friday last.

A City of Health.

Dr. Richardson will doubtless be glad to learn that at least one city in the United Kingdom has arrived at that state of absolute hygienic perfection so vividly sketched by him at the recent Brighton Congress. Carlisle is the happy city; its death-rate is reduced to 11 per 1,000, and according to the report of the Medical Officer of Health even this microscopic rate of mortality does not include one from preventible diseases. What a state of bliss to feel that by living in "Hygeia" people only die of old age, and that the average of life, according to these statistics, is ninety years. What a rush there will be to secure a residence in this favoured spot when these facts become known! Let us hope, in its perennity, and also that a *very* cold shoulder will be given to the Rev Hume-Rothery and the rest of his anti-vaccination agitators should they attempt to establish a *locale* in this "City of Health."

Dr. Deville's Case.

A question having been put to the President of the Local Government Board in the House of Commons last Friday relative to the dismissal of Dr. Deville from his post of Medical Officer of Health for Harrogate, we think it right to furnish particulars of the case lest any misapprehension may exist in the minds of the profession or the public from the necessarily meagre account given in the daily press. At the outset we may remark that from reliable and disinterested information received, we fear Dr. Deville is a victim of petty spite. Recently he read a paper before the Yorkshire Branch of the Medical Officers of Health Association, in which was discussed the Sanitary Condition of Watering Places. The Harrogate Commissioners were annoyed at some of the remarks contained in the said paper, and called him to account for them in a very peremptory manner. Dr. Deville naturally felt annoyed and insulted, that in the due exercise of his functions he was to be denied the privilege of making a communication on so important a subject to a body of fellow practitioners, and refused to meet the Board. Thereupon he was summarily dismissed, and another medical officer sought to fill his post. We believe that up to the present time no one has applied for the appointment, and that Dr. Deville is sustained in—to our minds—the dignified and proper course taken by him by the profession and the public of the locality. We await the result of the Government inquiry with confidence, feeling assured that when the action of the Harrogate Local Board has gone through the sifting of an official investigation, our *confrere* will be found to have exercised a wise discretion in refusing to accede to, or acknowledge the dictatorial interference of the body in question.

THE Anniversary Session and Dinner of the St. Andrews Graduates' Association, took place at St. James's Hall, on Monday last.

THE amount received for the Memorial to be erected to the memory of the late Sir J. Cordy Burrows, F.R.C.S., Mayor of Brighton, already exceeds £500.

THERE will be a vacancy for assistant-physician to the Rotunda Hospital shortly, Dr. A. V. Macan's term of office being about to expire. The appointment, we believe, rests with the Master.

BETWEEN twenty and thirty persons, principally women and girls, perished in the fire at a carpet manufactory, Ayr, Scotland, on Friday last, the door of the room in which the poor creatures were working being locked at the time the conflagration occurred.

NOTICE has been given that an examination of candidates for commissions in the Medical Service of the Royal Navy will be held at the University of London, Burlington Gardens, on Monday, Aug. 14, 1876, and following days, at ten o'clock.

HER Majesty's Commissioners have lately announced their intention of realising from their land possessions at South Kensington a considerable sum—it is said about £350,000—and applying it to those objects which promote science and art, as soon as the funds can be obtained.

ON the Cricket Ground of the Hull Church Institute a gentleman, 25 years of age, was batting, when the ball rising sharply from the pitch struck him on the head. He fell to the ground insensible, and in that condition was carried home, were he shortly afterwards died.

THE medical men having seats in the Legislature—39 in the Chamber of Deputies and seven in the Senate—met at Versailles to form themselves into an extra-Parliamentary Committee to confer on all Bills affecting health and pauperism. They elected M. Laussedat as President, and appointed two committees to consider legislative proposals on rural poor relief and on mineral waters.

THE Council of the Irish College of Surgeons has resolved :—"That it be referred to the Education Committee to consider the present course of study required for the licence of this College, and the best means to be adopted to secure a due performance of, and attendance on, such courses of study."

This resoution is a reaffirmation of a former resolution adopted at the time that the certificate system was brought under the notice by the Council of the Rev. Professor Houghton. It was reserved to the new Council to give effect to the resolution, which no doubt they will do immediately upon their reassembling after the summer recess.

Literature.

PHTHISIS. (a)

A TREATISE useful to the practitioner, and most important to the progress of medicine as a science. Dr. Flint has recorded the histories of over 670 cases of phthisis, and this work is the careful analysis of the record, following the example of Louis.

There are six chapters treating of the morbid anatomy, etiology, symptomatic events, prognosis, treatment, and physical signs of phthisis.

Dr. Flint acknowledges that the morbid anatomy is not given by him as completely as it might be, as there is no description of the microscopic appearances, and he has limited the post-mortem examination to the lungs.

As regards the extent of the disease, Louis found that one lung only was affected in seven of the 123 cases he examined. Dr. Flint has found only two cases in eighty in which the morbid changes were limited to one side. And in only three cases of the eighty examined did the deposit of tubercle appear to have begun below and advanced upwards ; in all the others it had followed the general law. Cavities existed in the great majority.

In describing the morbid appearances Dr. Flint uses the term "grey granulation" to apply to the earliest stage of the tubercles, "tuberculous exudation or infiltration" to denote the cheesy exudation. Tuberculous abscesses he speaks of as "liquefied morbid products." Proceeding to consider the importance of grey miliary granulations, whose presence has been exactly noted in twenty-six of the cases, he concludes that in a very large number of instances they are not of sufficient consequence to warrant the statement made by Niemeyer—viz., "the greatest danger for the majority of consumptives is that they are apt to become tuberculous," the term tuberculous being here limited to the miliary disease. Dr. Flint adds : "The greatest danger for the majority of consumptives is due to the amount of injury of the pulmonary structure, from exudation, liquefied morbid products, cavities, interstitial pneumonia, and lobular emphysema, with pleuritic effusions, perforations of lung, pneumo-hydrothorax, intestinal ulcers, enlarged mesenteric glands, peritonitis, and other intercurrent affections."

The pathology chapter includes notices of the presence of these changes, and of pulmonary apoplexy, gangrene, and dilatation of bronchi, but no allusion is made to aneurisms of the pulmonary arteries.

In the second chapter etiology is discussed. The ages of 583 patients are recorded, of whom 39 were from ten to twenty years old, 307 were from twenty to thirty, 132 from thirty to forty, and 67 from forty to fifty.

The disease occurred much more frequently in males than in females, there being 505 cases among the former, 164 among the latter.

The occupation has been recorded in 218 cases, of which nearly one-sixth were clerks or book-keepers, confirming the general opinion that sedentary pursuits and confinement indoors have an important bearing on the disease. The habitual inhalation of irritating particles is associated with only two cases, occurring in stone-cutters.

Pleurisy is noted as having preceded the appearance of phthisis in 22 of the cases, in some of which the author thinks that there was no pathological connection between

(a) "Phthisis : its Morbid Anatomy, Etiology, Symptomatic Events, and Complications, Fatality and Prognosis, Treatment, and Physical Diagnosis." In a Series of Clinical Studies. By Austin Flint, M.D. London : J. and A. Churchill.

the two diseases. He has only found nine instances in which pneumonia preceded phthisis, and having some years ago tabulated 123 cases of pneumonia, has had no reason to think that any of these were followed by phthisis. On the other hand, he confirms the statement made by Louis, that "when persons already tuberculous are attacked by pneumonia, the end is generally in recovery."

As the term bronchitis is used loosely by patients, little value can be attached to their statements about this disease, and very often they would thus speak of the hard dry cough which was really incidental to phthisis.

Dr. Flint appeals to the experience of medical men as to tubercular disease taking its origin from bronchitis, and asks whether bronchitis—a bilateral disease—is likely to give rise to tuberculous exudation, which is generally found on one side much earlier than on the other; and finally, is *bronchitis*, even in the smaller tubes, likely to give rise to "*chronic pneumonia?*"

These arguments against considering ordinary phthisis as a "chronic catarrhal pneumonia" coincide very nearly with the views of the causation of phthisis given by Louis in his work on the disease, and by Ruehle in Ziemssen's "Cyclopædia of Practical Medicine."

Hæmoptysis is not found to be a *cause* of phthisis, but an antecedent event, occurring in sixty-one cases before persistent cough had set in.

Intermittent fever is noted in twenty-five cases as having preceded the phthisis, but in five cases there is some reason to doubt the malarious origin of the attacks. The unquestioned cases are, however, numerous enough to show that this form of fever does not ward off phthisis.

Perineal fistula was found in four cases. Syphilis has preceded in five cases; but the author says that inquiry was not often made on this point.

Diabetes is mentioned in one instance only.

The number of female patients liable to pregnancy was eighty-seven, and of these ten began the disease during, and twelve soon after, pregnancy. Six of the latter cases were in the period of lactation.

There is nothing of great importance on the subject of hereditary tendency in the book, as inquiry was not made in most of the cases.

The symptoms and complications form the matter of the third chapter, commencing with *hæmoptysis*. The whole series of cases was not analysed with regard to this feature, but it appeared in ninety-nine out of 180 cases; in seventy instances it recurred several times. One patient suffered as many as forty times.

Dr. Flint suggests congestion of a section of bronchial mucous membrane as the most probable cause of hæmoptysis, and regards this congestion as an early effect of tuberculous disease. Another view is that the hæmorrhage results from rupture of small arteries, along the course of which tubercles are generally deposited.

The presence of bronchial hæmorrhage "renders the existence of tubercles in the lungs infinitely probable," provided that injury to the chest and vicarious menstruation can be set aside.

And so frequently is it found that phthisis is present with or follows the bronchial hæmorrhage, that it is best to act as though the tubercular disease was impending, even when the physical signs cannot be clearly made out. This bronchial form of hæmoptysis is rarely fatal (unlike the cavernous form in advanced phthisis), and apart from the mental effects of the discharge, is often rather beneficial in its results, as is shown by analysis of the ninety-eight cases in which the symptom was present.

Fifty-eight of these recovered or improved during five years, while of eighty-one cases in which hæmoptysis was absent only twenty-three recovered or improved. The amount of loss of blood does not appear to have had any influence.

On the *treatment* of the hæmorrhage the following suggestions are made:—Encourage the patient by hinting at a favourable result, and do not press rest and other hæmostatic treatment to a degree likely to favour the tuberculosis. In one case the author witnessed the direct benefit arising from tying ligatures round each of the limbs during the hæmorrhage.

Diarrhœa was present in thirty-one cases, and in nearly all those examined after death ulceration of the bowels was found. Moreover, the histories of patients suffering from this symptom lead to the conclusions that the intestinal ulcers seldom heal, and that the complication materially shortens the duration of phthisis. It is to be remarked that, though the ulcers persist, the diarrhœa may cease in some cases.

Perforation and hæmorrhage are among the bad results of this affection.

Pharyngitis is noted in twenty-four cases—probably was present in many others. The sixty-one cases of *Laryngitis* may be taken as the whole number. It caused more distress in the ingestion of food than by permanent dypsnœa.

The laryngeal affection is probably secondary to the lung affection in the majority of cases.

Pleurisy, with effusions, strange to say, does not seem materially to affect the duration of the disease.

Pneumo-thorax appeared in twenty-four cases. Free incision into the cavity of the pleura is recommended by the author.

Perineal fistula (fistula in ano?) existed in thirteen cases, and in some instances seemed to give relief, but, on the whole, did not affect the course of the disease.

Chapter IV. treats of *fatality* and *prognosis*.

Acute miliary tuberculosis has much dyspnœa, febrile excitement, a short course, and after death exhibits miliary tubercles without cheesy exudation, softened products, or cavities. One case seems to have run its course in about eleven days.

In considering the cases of recovery, Dr. Flint states that phthisis may be arrested and recur at a later period, recovery being said to take place if pulmonary symptoms disappear and the general state of health become as good as before the attack, this improvement being maintained for some months.

He then gives details of forty-four cases of recovery, and from his examination of them, concludes that smallness of extent of lung affection, general tolerance of the disease by the system, and resolute character of the patient are the circumstances most favourable to a good end. He also finds that many complications, such as hæmoptysis, perineal fistula, and chronic laryngitis do not much affect the length of the disease.

Arrest of the morbid changes is noted in thirty-one cases in which there was not absolute recovery, but the disease seemed retrogressive or stationary. Ten cases are included in a slowly progressing class, which cases lasted for periods varying from eight to forty years before death supervened.

We may conclude from the histories of these arrested and slow cases that they are favoured by the conditions which seem to lead to recovery.

Statistics do not always afford the results which we expect from them.

The duration of the disease is studied in 112 cases which were observed till death. The commencement of persistent cough is taken as the starting-point of the disease, and the average length is found to be thirty-three months. This result occupies a middle position in the mean durations given by other observers. The extremes in Dr. Flint's fatal cases are eleven days (in acute miliary tuberculosis) and forty years.

The question of free use of alcoholic liquors comes in in several places in the work. In relation to the fatal issue, the author's observations lead him to say that temperance does not delay it; and he has seen cases where as much as a pint of whisky has been taken with benefit daily for years by a girl of 18.

Chapter V. gives the results of treatment.

One remarkable fact is that in many of the instances in which arrest of the disease, partial or complete, took place, there was no medicinal treatment to speak of.

Two cases recovered among the eighty-four in which

cod-liver oil was given ; two cases among the sixteen in which hypophosphites entered into the treatment; and two cases of recovery occurred among the fifteen patients who took alcoholics freely.

The discussion of hygienic treatment includes nothing about the effect of mountain air, which is to be regretted.

The conclusions drawn from a summary of the hygienic treatment are as follows :

1. Benefit is derived in a large proportion of cases from change of residence, and is due more to incidental circumstances than to any special climatic agency.

2. Change of habits from the in-door and sedentary to out-door and active is more favourable than any other hygienic measure.

3. To this last the benefit derivable from a change of occupation is generally due.

4. Sea voyages are very often productive of good.

In suggestions for the treatment of phthisis, Dr. Flint recommends the use of cod-liver oil, either pure or in emulsion, unless the stomach seems disordered by it. Half-an-ounce to be taken three times a day, shortly after meals.

As to pancreatic emulsion, he says that he has seen cases in which it was "apparently useful."

As stated before, the author has seen many cases in which alcohol in large quantities seemed to do good, and he says that he has seen no instances of bad moral effects from the habitual use of stimulants in phthisis.

The subject of tonics and diet is treated in a few words, confirming the usual course of action, viz., to give tonics to help the appetite and digestion, and give such food as can be best taken.

Dr. Flint laments that patients "should be deterred from being out of doors—save under the most favourable circumstances of weather—by the idea that the disease is liable to be increased in consequence of taking cold," as bronchitis is not likely to be caused by ordinary changes in the heat and moisture of the air.

The subjects of cold sponging, gymnastics, clothing, travelling, and sea voyages are fully considered in this chapter. As to marriage, the author concludes that it sometimes is beneficial to the patient, but is often injurious to the other party.

Under the head of "Physical Signs and Diagnosis"—in the sixth chapter—clear descriptions of the indications afforded by percussion and auscultation are given. The difficulty of recognising acute tuberculosis and fibroid phthisis is also alluded to.

In conclusion, we may say that the work does not appear to have been written to float any particular theory of causation or method of treatment, but to add to the clinical knowledge of a most important disease.

DEPUTATION TO THE GOVERNMENT ON THE QUESTION OF VIVISECTION.

On the 15th an influential deputation waited upon the Earl of Carnarvon, who introduced the Bill in the House of Lords with respect to vivisection, to urge upon the Government the medical view of the subject. The deputation included upwards of 70 leading men from the hospitals of London and provincial towns.

Mr. Ernest Hart introduced the deputation, remarking that it was from the Parliamentary Committee of the British Medical Association, which was established for the promotion of medical science, and for the elevation of the character of the profession. They believed that both the advancement of the art of healing and the character of the medical profession were assailed by the measure brought in by the Government. He begged to remind his lordship that the agitation which led to the framing of this Bill was opened by the publication of charges which affected the whole profession, and which were of a nature peculiarly odious to men of sensibility, conscious of having in no way justly incurred them. Mr. Hart then dwelt on those portions of the Bill of which medical men more especially complained, and, in conclusion, pointed out that every one of the bodies and every one of the persons to whom this Bill was to be confided for its execution had protested against its terms.

Letters were read from Sir Thomas Watson, Bart., M.D., Mr. Erichsen, Sir William Gull, and others, warmly approving of the object of the deputation.

Various members of the deputation having spoken,

Lord Carnarvon, in reply, regretted that the shortness of time at his disposal prevented him from speaking as he should have desired to speak of the deputation before him, and of the admirable statements made. He wished to tell the deputation which represented so important and honourable a profession that the representations made to him would receive—not in the ordinary sense of the word, but really—the fullest consideration from his right hon. friend Mr. Cross, the Secretary of State for the Home Department, and from himself. He did not think it would be desirable to discuss now the details of the several objections raised against the Government Bill, but it was only due to the deputation that he should state that in the promotion of this measure the Government would not be insensible to the claims and to the rights of the medical and surgical profession. That was really not the case, and he could answer for it. (Applause.) Mr. Hart had alluded to the treating of medical men under this Bill as if they were, like other people of a different class, to have licenses. Now he wished to repudiate that most distinctly, and at once to assure the deputation that nothing could be farther from the ideas of the Government than to regard the medical profession in any other light than that which was due to a most noble and honourable calling. The Government had no desire to cast the slightest slur upon such a distinguished profession. Without discussing the principles upon which the deputation had spoken, he might mention that there was a very strong feeling in the country upon this subject of vivisection, and it would be the duty of the Government to weigh both sides of the question. That was all he believed he could say, except to assure the deputation, which so ably and so numerously represented the medical profession, that the observations made by them and their proposed amendments should during the next few days receive his most anxious and respectful consideration.

Dr. Quain, referring to one remark made by his lordship, that no one could suppose the Government of which his lordship was a member capable of wilfully insulting and degrading the profession of medicine, said the Bill had that effect. The Bill was the result of an artificial excitement produced in the public mind by unfounded and exaggerated statements, widely circulated, accusing medical men, young and old, as persons constantly engaged in practising cruel experiments on animals. The Government, strong as it was, and supported by the report of its own Royal Commission, could well afford to stand between these well-meaning but mistaken fanatics who got up this excitement and the medical profession.

The force of the arguments employed by the medical deputation which waited on Lord Carnarvon to remonstrate against some of the provisions of the Anti-Vivisection Bill is, in the opinion of the *Standard*, undeniable, and if the question is to be settled by reason, or indeed if reason is to have anything to do with its final adjustment, those objections must be obviated or the Bill must be dropped. It is true that the deputation waived many strong and general arguments which we have employed on various occasions, and with which there can be little doubt that they fully concur. They confined themselves to objections not inconsistent with the general scope of the measure, and with the acceptance of such restrictions on experiment as are not fatal to the very existence of experimental physiology. Even if all the amendments they recommended were made, the Bill would remain a very bad one ; but if passed without them, it would simply annihilate at once physiological experiments and scientific inquiry into the cause and cure of disease. Lord Carnarvon admitted the importance and authority of the deputation. We greatly regret that Lord Carnarvon's reply to the depu-

tation was not of a more satisfactory character. It was mere matter of course that he should promise to consider the arguments pressed upon him by such grave authority. That he should bring into the scale against them, as of commensurable, if not equal weight, the mere clamour of ignorant multitudes is of no good augury; that he should declare his intention to adhere to all the main principles and provisions of a measure which has evidently been drawn up without the slightest knowledge of the subject matter or consultation with well informed persons is a very unpromising indication of his own temper. The absurdities of the Bill are so many and so great that the wisest course would be to drop it altogether, and substitute for it one drawn by intelligent men, not ignorant of science, after hearing all that science and medicine have to say. If this is not to be, it should be referred to a select committee of practical men, careful not to hinder the progress either of abstract or curative knowledge. If it is to be pressed through in the unpliant spirit indicated by Lord Carnarvon's peremptory sentences it will invite defeat in the Lower House, and at any rate will be mercilessly exposed in debate, while its passage would be at once a discredit to the nation, a hindrance to medical knowledge and scientific progress, and a mischievous weapon in the hands of silly and violent partisans of which both the legislature and the country would ere long repent. And above all the enactment by two bodies of sportsmen of a measure professing to protect animals against the cruelty of doctors and physiologists would be a piece of unconscious hypocrisy and sublime Pharisaism that would move the civilised world to contemptuous laughter, and —which is much worse—make the cause of humanity to animals ridiculous for a generation to come. The beasts have good cause, indeed, to pray for deliverance from their present "friends."

Medico-Legal Intelligence.

HIGH COURT OF JUSTICE—CHANCERY DIVISION.

Before Vice-Chancellor Sir ROBERT MALINS.

TUFNELL *versus* THE CROWN.

This case came on for hearing on Thursday last, as a petition of right on the part of Dr. T. Jolliffe Tufnell, who has held the office of President of the Royal College of Surgeons of Ireland, and is very well and favourably known in the profession at home and abroad. The case made by his petition of right was to this effect:—He entered the Army in June, 1841. In 1846 he was stationed in Dublin, as an assistant-surgeon upon the Staff, and was placed in charge of the then existing Provost Prison. Shortly afterwards the new District Military Prison was erected in Dublin. In October, 1846, he applied to the then Secretary at War for the permanent medical appointment to the prison, and wrote to him as follows:—

"Sir,—With reference to my application for permanent appointment to the Military Provost Prison, I have the honour to inform you, with a view of obviating any difficulty that may arise in naming me to permanent employ, that should the Right Honourable the Secretary at War, and the Director-General of the Army Medical Department, be pleased to confirm my present employment in Dublin, I have no objection to forego all further claims to promotion, regarding a permanent appointment as equivalent to increased rank, &c., &c.

"JOLLIFFE TUFNELL."

To this proposition the Government then in power acceded, and Dr. Tufnell entered on the duties of the office, and remained in it till December, 1874. In 1855 Lord Panmure, the then Secretary of State for War, appointed Dr. Tufnell Regius Professor of Military Surgery in Ireland, at a salary of £100 a year, with permission to take pupils not in the service at a fee of £3 3s. for each student. His total official income then was about £250 per annum. In June, 1860, the Regius Professorship of military surgery in Ireland was abolished, the establishment of a military medical school at Chatham having rendered the professorship unnecessary. Dr. Tufnell conceived that the Regius Professorship had been conferred by the Crown upon him for his life. He accordingly requested compensation in respect of its abolition. In July, 1860, he was gazetted as surgeon supernumerary to the establishment. In June, 1861, having completed 20 years full pay service in the Army, he assumed the style of Surgeon-Major. The grades of medical officers in the Army were four—(1) Inspector-General of Hospitals; (2) Deputy Inspector-General of Hospitals; (3) Staff or Regimental Surgeon, who, after 20 years' full pay service in any rank, should be styled Surgeon-Major; and (4) Staff or Regimental Assistant Surgeon. From 1860 till December, 1874, Dr. Tufnell continuously discharged the duties attaching to the medical charge of the military prison at Dublin; but on the 8th of December, 1874, he was compulsorily retired upon half-pay by the *Gazette* of that date. The petition did not state, but Dr. Tufnell said it was the fact, that he received in respect of the military prison a salary of £686 per annum, and that his half-pay now was £365 a year. He complained that, inasmuch as he was by the contract with the Crown in 1846 appointed to the medical charge of the military prison at Dublin during his life or until incapacitated by infirmity or misconduct, his compulsory retirement on half-pay when he was able and willing to do his duty had subjected him to a heavy pecuniary loss. He also said that he had applied, but without redress, to His Royal Highness the Duke of Cambridge; that, between March, 1867, and December, 1874, at least 23 medical officers, his juniors, had been promoted over his head to the rank of Deputy Inspector-General; that the appointment conferred on him in 1860 was no infraction of the condition in his letter of October, 1846, because it was given to him as compensation for the abolition of the Regius Professorship of Surgery—an office wholly distinct from that connected with the prison; and, after submitting that the only ground on which he had been passed over (excepting in the case of promotion for special services) was that he held a special appointment which was permanent and supernumerary, he prayed by his petition that he might be compensated and indemnified for the loss, damage, and injury sustained by him as above mentioned. To that petition of right the Crown demurred.

After hearing the contentions of counsel on both sides, the Vice-Chancellor delivered judgment against Dr. Tufnell, on the ground the case disclosed no real grievance, and that the petitioner being still an officer of the British Army, he was liable to its rules and regulations, and removable at the pleasure of the Crown.

THE PUBLIC HEALTH (IRELAND) BILL

was presented only on Saturday last, and as it contains 272 clauses, and consolidates a great many Acts which deal with a great many subjects, it will be readily understood that it is impossible for us to print any of its sections, or refer at length to its provisions. It is sufficient for the present for us to say that it greatly increases the powers and duties of sanitary authorities, transferring to them the most multifarious functions, in the execution of which the medical officers will be the motive power. If one-tenth of the duties which are imposed upon Boards of Guardians be discharged, it is entirely impossible that their sanitary officers can continue to act, except they be handsomely remunerated. To suppose that they will undertake such labours for the £5 or £10 now voted as salary, or even for the maximum which is awarded by the Local Government Board, is simply preposterous. Next week we shall give an abstract of those clauses of the Bill which are of special interest to the profession, and meanwhile, we trust the Bill will not be pushed through its stages before time has been given for its due consideration.

THE DUBLIN CORONERS BILL.

THE second reading of this Bill in the House of Lords is not fixed, and the Council of the Irish Medical Association have made arrangements to have its rejection or

amendment moved when the proper time comes. Meanwhile there is every reason to hope that fate has brought the measure to an untimely end. It was, as our readers are aware, a legislative job introduced by Mr. Sullivan for the purpose of giving his friend and *quondam* co-litterateur, Dr. Whyte, the coroner of the city, a monopoly of the coronership at a double salary, the job to take effect upon the death or retirement of Dr. William White, the second coroner, whose state of health was at the time quite hopeless. Within the last week the intentions of the Bill were anticipated by the death of Dr. White, and the Dublin Corporation, who would gladly have co-operated in this or any other little family job, had no option but to declare the place vacant, and to fix the 26th for the election of a new coroner. Before the Bill can be committed in the Lords, a fresh and sturdy coroner will be in office, and the contingency of a double salary for Dr. Whyte will be indefinitely postponed. The Council of the Irish Medical Association having taken the subject in hand, are not going to let it drop, but will contest both in Parliament and before the fiating judges the grossly illegal and corrupt system which has existed for so many years under the patronage of the Dublin Town Council.

In our last issue the circumstances of a case were narrated in which an operation had been performed by London surgeons upon a patient whose case had been declared hopeless and entirely unsuitable by the highest surgical authorities in Ireland, the result being speedy death to the patient. The case thus referred to was that of the Reverend Mr. Longfield, of the county Cork, and, though intended merely as an illustration of the same method of practice which is stated to have been pursued in the more recent case of Captain Leader, it was inadvertently made to appear as a statement of the circumstances attending that gentleman's death. The facts as stated by us last week are accurately true as regards the Reverend Mr. Longfield. In Captain Leader's case the disease is stated to have been cancer of the testis, extending up the cord, and capable of being felt in that position and up in the iliac regions, by the surgeons and the patient himself. He was seen, after attendance by the local practitioner, first by Mr. Butcher, and afterwards by Mr. Porter, the two highest surgical authorities in Ireland, who concurred in opinion as to the hopeless extent of the disease, and strongly advised against any operation. Nevertheless the patient was operated on in London, and with a fatal result. We are ourselves cognisant of more than one case in which patients declered by a concurrence of the best ophthalmic opinions in Ireland to be hopelessly blind, were operated on in London, apparently without hesitation, and certainly without the least benefit. As we have said, these cases, and others of similar import, have created in Irish surgical circles an unpleasant feeling.

Correspondence.

THE PROFESSION OF DENTAL SURGERY.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—The attempt to bring the influence of the medical profession to bear upon the training of dental surgeons can be of advantage only when medical men are made fully acquainted with the scope and requirements of dental surgery, an accurate knowledge of which they do not at present possess. The existence of special journals, while they render great service in bringing before the dental practitioner all that relates to his calling, tends to remove from the eye of the general practitioner much that he well might know, and more that it is needful that he should know if he would form a just opinion of the present state of dental surgery. The absolute necessity for a long special training in order to acquire moderate capabilities as a dental practitioner is very generally overlooked, and the power to pass an examination in surgery and to write a prescription is accepted as a sufficient education for the dental surgeon. But those whose powers constitute them efficient judges know full well that there is little difficulty in recognising what is required in the treatment of a case, but very great difficulty in acquiring the power to carry it into effect. To take out a large portion of the softened tissue from a carious tooth and to fill up the hole with a plastic material requires little skill; but to remove the diseased part as fully as may be, to leave the cavity in a form capable of retaining a long-lasting plug, and to introduce that plug—in fact, to perform the operation up to the highest standard of excellence, without an undue expenditure of time exhaustive to the patient and operator—requires great skill, a degree of skill gained only by patient training over at least two years in pupils naturally not inapt. Let any one interested visit the Dental Hospital, and watch the performances of students of one year, then those of two years' training, and, if possible, the operations of the more skilful teachers, let him then try his own hand, and all I have stated will be admitted. That which is true respecting filling teeth applies also to other dental operations. But the dental surgeon will be occupied three-fourths of his time in treating carious teeth, and, if his operations are rightly performed, he will have rendered good service, and secured the lasting gratitude of his patients.

Were it otherwise we should find medical practitioners using the leisure hours of their early professional life in the performance of dental operations. In truth the education of the surgeon does not embrace dental surgery. A man may be a member of the College of Surgeons or Physicians or of the Apothecaries' Company, and yet know nothing of dental surgery; and it would be unreasonable, and, consequently, all but impossible, to impose upon him a long and expensive training in a speciality he is not specially destined to practise; and, again, the knowledge acquired would be speedily lost unless constantly practised. That which would be true of the general surgeon applies with equal force to the dental surgeon, whose knowledge of general surgery fades from disuse by the time he acquired his general diploma; for his speciality will, if rightly practised, demand all his time and thoughts. He cannot remain an effective general surgeon if he would be a faithful dental surgeon. He may be a legally qualified practitioner, but, without use, the knowledge he acquired up to the level of a pass examination will speedily waste, and he will become morally disqualified.

These facts were fully recognised twenty years ago, when the College of Surgeons instituted its department of dental surgery, laid down a curriculum to be followed by students, and after examination granted a diploma of fitness to practise, under the title of Licentiate in Dental Surgery. In this curriculum certain subjects embraced in the general medical education, but scarcely needful to the dentist, such as midwifery, forensic medicine, and botany, &c., were left out, and in their stead special dental subjects were introduced, leaving the time and cost of the profession strictly unaltered. The wisdom of this course is shown in the fact that the Dental School, formed to meet the requirements of the curriculum, has from year to year increased the number of its students, who at the present time nearly approach one hundred; and that the education meets the necessities of the dental surgeon is proved by its voluntary acceptance by those whose purpose it is to follow dental practice. For it must not be forgotten that the legal powers given to the colleges in the dental charter are permissive only, hence the education is offered, not enforced. The value of the diploma has been steadily advanced by extending the educational opportunities, by gradually increasing the strictness of the examination, and by the addition of written to the *vivâ voce* questions. And the preliminary examination in arts now required of the medical student before entering upon professional studies will also be required of the dental student from October, 1877.

The licentiateship is the qualification needed by the dental surgeon, for no other indicates that the possessor is practically acquainted with dental surgery; and, surely, if we would gain our living by dental practice, we must before all else be skilful dentists. I use the word *dentist* because the public will call us dentists do what we will, just as they call the opthalmic surgeon an oculist; and if we suffer, it will not be by the name but by our want of worth.

I do not for one moment argue against the dental student taking a general medical qualification; on the contrary, I would urge the student whose means and time will allow, to take the membership or fellowship of the College of Surgeons or Physicians, and I would further advise him to take the B. A. of one or other of our Universities. But I do protest against

the student making a general qualification stand in the stead, and take the place, of the special one if he proposes to gain his living by our speciality.

Dental surgery some years back suffered greatly from one or other of two conditions. The practitioner had at the outset only a general medical education, or, in many cases, he possessed no education at all, and the suffering is not yet at an end; but the wise course taken by the College of Surgeons has already very greatly reduced the evil, and will doubtless ere long, to the exclusion of the incompetent, provide the public with a very efficient race of practitioners.

It is reasonably hoped that the permissive education, the success of which no well-informed person can deny, will become compulsory, and that a distinctive line will be drawn between the competent and incompetent practitioner, recognisable by the public.

The membership and licentiateship jointly may be said to meet the case, but they involve a higher and more costly education than either taken singly, and it is not reasonable to expect that all dental students will be prepared to meet the demands of the double qualification. For such, and they will probably form the majority, at least for some time to come, the licentiateship will suffice, as being the educational equivalent of the single qualification in the general practitioner.

There has been much loose talk about the status of the dental practitioner. We had better work more and talk less upon the education of ourselves and our fellows. The Legislature can neither give nor withhold social status. The public will settle the question, and our position will be determined by our individual and collective professional and general culture, by our professional usefulness and scholarly attainments.

I remain, Sir, yours truly,

June 14th, 1876. JOHN TOMES.

NOTICES TO CORRESPONDENTS.

☞ CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

READING CASES.—Cloth board cases, gilt-lettered, containing 26 strings for holding each volume of the MEDICAL PRESS AND CIRCULAR, can now be had at either office of this Journal, price 2s. 6d. The postal regulations not allowing the Journal to be stitched, these cases will be found very useful to keep each weekly number intact, clean, and flat, after it has passed through the post.

A STUDENT.—We will give your question our consideration.

COMMUNICATIONS, Enclosures, &c., have been received from Mr. Erasmus Wilson, London. Dr. Tatham, Salford. Mr. W. MacCormac, London. Dr. Braidwood, Birkenhead. Dr. Hughlings Jackson, London. Dr. McClintock, Dublin. Dr. O'Gilvie Will, Aberdeen. Dr. Law, Brompton Consumption Hospital. Dr. Edmunds, London. Mr. Sewill, London. The Secretary of the Statistical Society. Dr. Brewer, London. Mr. E. F. Flower, London. Dr. Handsel Griffiths, Dublin. Mr. Kemp, London. Dr. Griffiths, Sheffield. Mr. C. J. Fox, London. Mr. H. Constable, Athenæum Club. Dr. Myrtle, Harrogate. Mr. Lankester, National Health Society. Mr. Hyslop, Church Stretton. Mr. Watson, London. Dr. Scraggs, Clogher. Dr. Wheeler, Dublin. Dr. Heeney, Belfast. Dr. Doherty, Dublin. Dr. Denham, Dublin. VACANCIES.

Salford Fever Hospital.—Resident Medical Officer for the new Fever Hospital. Salary, £100, with board and residence. (See Advt.)

Downpatrick District Lunatic Asylum. Assistant Resident Medical Superintendent. Salary, £100, with board, &c. (See Advt.)

Owen's College, Manchester.—Demonstrator and Assistant Lecturer on Anatomy. Salary, £100 per annum. Applications, under cover, to the Registrar.

Liverpool Dispensaries.—Assistant House-Surgeon. Salary commencing at £108. Applications to be sent to the Secretary.

Birmingham General Dispensary.—Resident Surgeon. Salary £170. Applications to the Secretary.

York Rural Sanitary Authority.—Medical Officer of Health. Salary, £150. Full particulars of the Clerk, 1 Museum Street, York.

Lancaster County Lunatic Asylum.—Resident Medical Superintendent. Salary commencing at £400. Mr. Sharp, Solicitor, Lancaster, will furnish full information.

Hants Lunatic Asylum, Knowle. Two Assistant Medical Officers. Salary of Senior, £150; Junior, £100, with board. Address Dr. Manley, Knowle, Hants.

Ipswich Asylum. Assistant Medical Officer. Salary £100, with board. Apply to the Medical Superintendent.

St. Thomas's Hospital.—Resident Assistant Physician, and a Resident Assistant Surgeon. Salary £100 in each case, with board. Full information of the Treasurer's Clerk.

West London Hospital, Hammersmith.—Assistant-Surgeon. Particulars of the Secretary.

Warwick County Lunatic Asylum. Junior Assistant Medical Officer. Salary £100, with board. Address the Medical Superintendent.

Hospital for Sick Children, Great Ormond Street, W.C. Third Assistant-Surgeon. Honorary. Candidates must be Fellows of the College of Surgeons of England.

APPOINTMENTS.

ATKIN, N. E., L.R.C.S.I., L.K.Q.C.P.I., Medical Officer for the Hill District and Vaccinator for the Brynmawr District of the Crickhowell Union.

BAYES, F. W. H., M.R.C.S.E., Medical Officer for the Snoring District and the Workhouse of the Walsingham Union, Norfolk.

BOWES, J. I., M.R.C.S.E., Assistant Medical Officer to the Northampton County Asylum.

Marriages.

CROSS—PARKER.—On the 14th inst., at S. James's Church, Paddington, John Cross, B.A., M.D. Cantab, of 7 Stanhope Terrace, Regent's Park, to Marianne, second daughter of T. R. Parker, Esq., of Maida Hill, W., and niece of G. Henderson, M.D.

MANNING—THORNE.—On the 15th inst., at the parish church, Shifnal, Shropshire, Leonard Archibald Manning, M.A., M.B. Dub., of Llanymynech, Shropshire, to Essie Anna, elder daughter of the late William Thorne, of Haughton, Shifnal.

NEWMAN—CUMMING.—On the 12th inst., at Milverton, Somersetshire, Wm. Newman, M.D. Lond., F.R.C.S.E., of Stamford, to Charlotte, daughter of the late Walter Cumming.

Deaths.

BROWN.—On the 12th of June, at Lewisham, Samuel Stainton Brown, M.R.C.S.E.

DAVIES.—On the 3rd of June, at Warrington, John Davies, M.D., aged 71.

MYRTLE.—On the 6th of June, at Rutland Street, Edinburgh, John Young Myrtle, M.D., aged 64.

PECK.—On the 8th of June, at Richmond Road, Barnsbury, William Ralph Peck, M.R.C.S.E., aged 61.

PERKINS.—On the 9th of June, at Rye Bank, Wem, Richard Steele Perkins, M.R.C.S.E., aged 65.

SMITH.—On the 2nd of June, at Tonge, Bolton, Lancashire, William Smith, Surgeon, aged 33.

STEAD.—On the 9th of June, at Southport, Joseph Stead, M.R.C.S.E., late of Cheetham.

WHITLOCK.—On the 4th of June, at sea, on board the R.M.S.S Para, Hubert Carlton Whitlock, M.R.C.S.E., Health Officer of the City of Demerara, British Guiana, son of the late Hubert Whitlock, Exeter, Devonshire, aged 42.

OBSTETRICAL SOCIETY OF LONDON.—The Quarterly EXAMINATION for MIDWIVES will be held on Wednesday, July 12th. Candidates should apply at the Society's library, 291 Regent street, W., on or before July 1st.

GENERAL NURSING INSTITUTE for TRAINED HOSPITAL NURSES.
5 Henrietta Street, Covent Garden, W.C.
A. EBSWORTH, F.R.C.S., Director.

DR. TAMIN-DESPALLES, of Contrexéville (Vosges, France), requests his English *confrères* who desire information respecting this hydro-mineral station for cases of gout, gravel, liver complaints, vesical catarrh, habitual constipation, leucorrhœa, &c., to specify their questions in a letter, or to merely forward their names, that he may send them advice as to the cases in which the uses of the waters of Contrexéville are indicated.

ADMIRALTY.—MEDICAL DEPARTMENT OF THE NAVY,
9, New Street, Spring Gardens, S.W. 6th June, 1876.

NOTICE is hereby given, that an EXAMINATION of CANDIDATES for Commissions in the Medical Service of the Royal Navy will be held at the University of London, Burlington Gardens, on Monday, 14th August, 1876, and following days, at ten o'clock.

Candidates must present themselves at this Department at eleven o'clock on Thursday, 10th August, 1876, when, should they be found in all respects eligible, they will be permitted to appear for examination.

The necessary forms to be filled up by candidates will be supplied on application to this Department, and should be returned as early as possible.

A. ARMSTRONG, Director-General.

BOROUGH OF SALFORD FEVER HOSPITAL.—The General Health Committee of this Borough are desirous of receiving applications for the appointment of RESIDENT MEDICAL OFFICER for their new Fever Hospital. Salary £100 per annum, with board and residence in a house separate from the Hospital.

Also for the appointment of MATRON and HOSPITAL SUPERINTENDENT for the same Institution. Salary £40 per annum, with board and residence.—Applications, with testimonials, to be sent to me not later than the 24th instant.

JOHN TATHAM, M.D., Medical Superintendent.

Town Hall, Salford, June 7th, 1876.

TO APOTHECARIES and PHARMACEUTICAL CHEMISTS.—TO BE SOLD, a first-class compounding establishment, fitted up with all modern requisites of the trade, having a good stock of the best drugs. There is a good trade in the compounding of prescriptions and sale of medicines in connection with it. Has been established over ten years, in a city of over 9,000 inhabitants; is well adapted either for an apothecary or pharmaceutical chemist. To be disposed of on account of the Proprietor having accepted an appointment in England. Immediate possession can be given. To an energetic man this would be a splendid opening, as the trade is improving, and has been for years. Application as to terms or for an inspection of the premises to be addressed to the Proprietor, Apothecaries' Hall, Russell Street, Armagh, Ireland.

THE NATURAL HISTORY OF PULMONARY CONSUMPTION. (a)

By A. B. Shepherd, M.A., M.B., F.R.C.P.,
Physician to the Victoria Park Hospital for Diseases of the Chest; Assistant Physician to St. Mary's Hospital; &c.

LECTURE I.—(Continued.)

Mr. President, Fellows, and Gentlemen,—In my first lecture, I attempted to show that certain cases of disease included under pulmonary consumption by writers living in different countries and at different periods of time—all of them workers of the most trustworthy authority—ought not to be classed under that affection. My reasons for taking up that position, were, that in none of them, or at any rate in the most typical cases, could death be said to occur from disease of the lungs; that the series of clinical symptoms was essentially alike in all, and absolutely characteristic of a disease to which the term "tuberculosis," if it be preserved at all, may be given, but given only as a name for a certain and well-defined group of symptoms, and not in relation to any particular growth or product. I stated reasons why I am prepared to hold with Buhl and others, that this disease is one of infection, never causing independently any peculiar destruction of lung-tissue; and I think I demonstrated that, excepting in cases where the disease supervenes, as sometimes it does, on some former destructive affection of the lungs, the most marked characteristics of pulmonary consumption, as defined by Aretæus, by Sydenham by Morton, were absent. Almost every writer without exception tell us that there was no emaciation; that the lungs, beyond being more red than normal, and surcharged with innumerable minute granulations, were sound. Bayle (b) in contradiction of his own definition of phthisis, exclaims in reference to his second case, that of a postilion aged 24, who died from apnœa twenty-two days after being attacked by a dry cough, his lungs being found crammed with miliary granulations, "In the beginning of November, the cough not having yet commenced, where is the physician who, on examining this young man, who seemed to enjoy the finest health, and whose chest was perfectly well-formed, would have suspected a consumption?" And it was from cases of this kind, as compared with others of which I shall speak today, that I hoped to show that this is never the commencement of the ordinary phthisis of this country. Therefore it was that I insisted that the terms "tubercle" and "tubercular," vague in their primary use, have become vaguer in their secondary one; and if in any degree I have been able to assist in encouraging some strict definition of terms so commonly used, I shall not have wasted time in a fruitless strife of words.

I pass on to consider the ordinary form or forms of consumption, keeping before me the definition of Morton, to which may be added the sanction of Bayle: "The lung is the only organ which constantly undergoes organic change in pulmonary phthisis;" and that of Portal,(a) who, in his chapters on the examination of bodies dead of this disease, says, "The lungs always undergo change."

One of the great facts which Addison set himself to demonstrate was, that pneumonia (b)—I quote his own words—"leaves behind it divers forms of induration of the pulmonary tissue, all of which have been somewhat indiscriminately, but I believe erroneously, regarded as modifications of tubercle or of tubercular infiltration. Such indurations of the pulmonary tissue, altogether independent of tubercle, are, I am more and more persuaded, of very common occurrence; and moreover venture to predict that the time is not far distant when it will be generally acknowledged that they have not by any means commanded the attention they deserve." I am content to confess my

(a) Goulstonian Lectures.
(b) *Op. cit.*, p. 130; Barrow's translation, Liverpool, 1815, p. 143.

(a) *Observations sur la Nature et sur la Traitement de la Phthisie Pulmonaire.* Paris, 1792.
(b) *Guy's Hospital Reports*, ser. ii, vol. iii, p. 3.

belief in Addison's prediction, though its fulfilment is hardly yet come. But since the time of Morton with sixteen varieties of phthisis, Sauvages with twenty, Portal with forty, Baumes with three, Bayle himself with six, and yet doubting whether there may not be more, the tendency has certainly been to arrive at some simpler and truer statement of the phthisical process; even though Buhl, perhaps the clearest writer of to-day on the subject, must needs divide and subdivide varieties. The division I take to-day for my own convenience is to some extent similar to that adopted by Dr. Peacock in the paper to which I have already referred, though I must still insist upon distinguishing between the effect of intra-alveolar and extra-alveolar products; and so far, in its larger characters, my division agrees with that given by Buhl. At any rate, I cannot but feel that the clinical corresponds here with the pathological grouping.

All forms of phthisis may, I think, be classed according as to (1) whether dead or dying tissue-elements are found choking up the alveoli and bronchi, and leading to further destruction of the respiratory organ; (2) whether changes occur in the walls of the vesicles and bronchi, robbing that organ of its function in a different way; or (3) whether the interstitial tissue undergoes metamorphosis, interfering in yet another fashion with that same necessary function—on the imperfect and abnormal performance of that function depending all the symptoms of innutrition and fever which go to make up pulmonary consumption. To the first group belongs that form of the disease to which Buhl has given, I think correctly, the name of "desquamative pneumonic phthisis;" to the second is due that form next common in frequency, caused by long-standing bronchitis and emphysema; and to the third, those fibroid changes resulting in the same true symptoms of consumption, differing somewhat clinically and pathologically, as they are caused by alcoholism, syphilis, or anthracosis. All these forms of consumption fall under the definition of Morton: all owe their origin to primary disease of the lungs; all are accompanied by symptoms due to that lung disease; all alike bring in their train that general wasting of the bodily structure and strength which is included in the very term "phthisis"—"consumption." Upon the first and second forms, if not upon the third, a further process, resembling that of "acute tuberculosis," may and does frequently supervene, constituting Waldenburg's "phthisis combinata;" but the series of symptoms in these cases is in strong contrast to those alluded to in my first lecture. I need scarcely state, after what I have already put forward, that my own work, clinical and pathological, leads me to support the proposition of Addison (*a*), "that inflammation constitutes the great instrument of destruction in every form of phthisis."

I proceed to speak of the first form of morbid change, which, leading to destruction and death of the breathing surface, originates, as I believe, in catarrhal inflammation of the epithelium lining the alveoli and smaller bronchi, and is the form under which the common pulmonary consumption of this country most frequently occurs. This view I do not intend to support by reference to the numerous authorities who from the time of Broussais downwards have upheld the inflammatory origin of phthisis. I propose, on the other hand, to show, from writers who uphold the tubercular origin, how far their descriptions are consistent, as they profess them to be, with the supposed development of an extra-alveolar miliary nodule into an intra-alveolar and interstitial exudation or infiltration. I shall, however, press into my service especially such plates as exist, by whomsoever prepared, in illustration of what certain writers mean by certain *post mortem* appearances, the correctness or the reverse of such appearances being open to the judgment of those who inspect them. The agreement of these drawings with what each of us can see for ourselves in the *post-mortem* room being allowed, the general experience of all is conclusive that a drawing, however inartistic, represents those facts which the draughtsman most certainly appreciates for himself,

> "Quæ sunt oculis subjecta fidelibus, et quæ
> Ipse sibi tradit spectator."—Hor., *A. P.*, 181.

Of the clinical symptoms of the ordinary phthisis of this country it is not for me to speak. The sequence which Morton sketched—the general wasting of the body, due in the very first instance to the local mischief in the lungs, and accompanied from the very commencement by cough, dyspnœa, and other signs pointing to those organs, joined with symptoms of pyrexia, at first of a low and hectic type, but increasing in intensity as it becomes also more frequently remittent — such is the every-day picture of that phthisis which, as Hippocrates noticed, occurs most frequently between the ages of eighteen and twenty-five, and of which Sydenham declares, "Atque hæc est præcipua Tabis species" (*a*). Modified by age, at any rate, in its rapidity of march, here swiftly striking down the young and growing, there clinging to the full perfected man, till, with a grim satire on the "survival of the fittest," it robs him of the later years of manhood—it preserves, with this one exception of rapidity, the same marked outlines to recall which further to your minds would savour of impertinence on my part. It is on the interpretation of the morbid appearances found that differences of opinion alone arise. Death in this form of phthisis is brought about, as Aufrest (*b*) has already stated, either, though this is rare in adult life, by the supervention upon pulmonary disease of longer or shorter standing of what, with Empis, he calls "granulia"—that is to say, of "acute general tuberculosis;" secondly, as an acute galloping consumption; or thirdly, as the termination of a long chronic process.

The appearances found in the second and third class of cases seem to me to be the most unmixed, though more difficult to unravel in the type of galloping consumption, and are, as far as I can see, the probable key to the commencement of this affection. The signs during life are, of rapid consumption, those of consolidation at the apex generally of both lungs, followed very rapidly by signs of breaking down of the lung-tissue, both consolidation and destruction creeping swiftly downwards to the base. The signs in chronic consumption are a very slow procession of the same features over one or both lungs. On *post-mortem* examination, these organs, in addition to the cavities of larger or smaller size present, and portions of tissue in a condition easily broken down by the finger, exhibit here and there those grape-like masses which are most marked in the chronic form of the disease. To this arrangement in the latter form Laennec evidently refers when, in a description of one of his plates, he recognises it as a collection of "crude tubercles," at the same time comparing it to the club on playing cards, drawn even at this day more correctly on the cards of Paris than on those of London, as a stalked trefoil. (*Op. cit.*, plate i, fig. 7.) This same racemose arrangement is seen in Carswell's plate (*c*) which he describes as a delineation of tubercle, a delineation which Sir Thomas Watson praises, and adopts as a representation of his own views. Bock, in his *Atlas of Physiological Anatomy*, published at Leipzig in 1855, gives in Plate xxiii. a very good illustration of a most common *post-mortem* appearance—cavities in the apex, and in the base clusters of round bodies. With him, again, these latter are "tubercles." Colberg (*d*) in 1867 gives the naked-eye appearances of chronic catarrhal pneumonia (phthisis pulmonalis), in which the same clusters are said to be due to the cheesy degeneration of the contents of the

alveoli: and Thaon (*a*) in 1873 gives a plate resembling Colberg's in everything but colour, the description of which reads as follows: "Fibrous granulations, or the granulations of Bayle arranged in clusters; isolated clusters: confluent clusters: bronchial ramifications: normal pulmonary tissue." But, whether called by the various names of tubercle, chronic catarrhal pneumonia, bronchopneumonia, it must be conceded that all these plates have these points in common: they profess to represent the appearances found in the bodies of those who die of pulmonary consumption; they represent the naked-eye appearances of what we find to-day on the *post-mortem* table in bodies dead with the same symptoms described in connection with these cases; they represent an intra-alveolar and intrabronchial product, with more or less surrounding inflammation and more or less surrounding induration.

To Addison's lithographs I have already referred. Bayle gives no plate of his own; but Barrow (*b*), who translated his work in 1815, gives two woodcuts of a lung containing ragged cavities of different sizes and bronchi cut transversely; the latter being, according to him, tubercles. Not only do the woodcuts, but the very words of the late Dr. Hughes Bennett, (*c*) point to the same intra-alveolar, intrabronchial production of what he names "tubercle." He asserts: Numerous successful injections of pneumonic, tubercular, and cancerous lungs, in my possession, demonstrate that the exudation in all is poured out in the same manner, and occupies the same position in the pulmonary textures;" that is, as the preceding sentence tells us, fills the interior of the air-vesicles. The same growth of "tubercle" in the lung from the intra-alveolar epithelium was the view of Schrœder van der Kolk. (*d*) The same too, had been apparently (*e*) Virchow's earlier view, though, (*f*) later, in his criticism of Reinhardt, he held the "tubercle to originate from connective tissue." Such, if I may be allowed to state my belief, is the view held by a large number in this room; viz, that the product is intra-alveolar.

This intra-aveolar origin of the pathological products of the commonest form of phthisis being for the moment allowed, the rapidity of proliferation of the epithelial cells, growing closely side by side, may easily be judged of by comparison with the rapid enlargement and proliferation of the cells of irritated articular cartilage, or with that of the cells of the inflamed cornea. But, with this rapid proliferation of cells, the portions of lung attacked begin to lose their function as breathing surfaces, and to take on the function of secreting glands. It is scarcely possible, I I think, to overlook the likeness there is between, at any rate in their pathological aspects, the inflamed lung and the inflamed sebaceous follicle. The lung, in a state of chronic inflammation and of epithelial—or, if the word be better chosen, endothelial—growth, is very like a racemose gland, also in a state of chronic inflammation. In the description of one of his lithographs (*g*) which to my eye represents lobular products with recent pneumonia, or, in his own words, "a form of phthisis in which the disorganisation results partly from the softening of recent hepatisation, and partly from the disintegration of pneumonic induration more or less ancient," Addison draws what he conceives to be, "although rude and incorrect, some sort of analogy" between his "sthenic tubercles"—*i.e.*, the result pictured—and facial acne. I confess that I fail to see either the rudeness or the incorrectness of the comparison. A lung-alveolus is not so unlike a sebaceous follicle that its contents, like those of the latter, proliferating more rapidly in a condition of inflammation, and, to quote Morton again, "having a difficult exit," lead to further inflammation. Both become plugged with their contents; the contents of both undergo the same cheesy (oily) change, and set up the same inflammation and death in the secreting wall itself and the immediately surrounding tissues. And, as increased cell-growth cannot but be influenced to a very large degree by the simplest mechanical processes—of which fact no histologist can doubt—we might easily expect that in the loose and spongy tissue of the lung, as compared with the dense structures outside sebaceous glands, the death of the parts engaged is at the same time more rapid and more wide-spreading.

And this, as it seems to me, is the process—the great fault of which is its simplicity—which really does occur in the very large majority of cases of ordinary phthisis. If we take a portion, which seems most recent, of one of those grape-like clusters to which we have referred, we shall find pretty well the same microscopical appearances which Professor Klein has drawn in this vertical section through the lung of a child which died of acute tuberculosis. Here the masses found agree with Buhl's description of desquamative pneumonia. The alveoli and infundibula are distended by abnormal material. The intra-alveolar capillaries, as the disease advances, are no longer permeable, seem to disappear; as does the epithelial lining of the alveoli, still visible in the regions of latest change. Here is no stubborn tissue opposing its own vitality of the invading change. The cell proliferation in a few alveoli leads not only to its own death, to the death of the capillaries which first fed it, and to the death of the wall which supported those capillaries: by easy extension, it passes onward to more alveoli, more infundibula, till bronchioles and bronchi are caught in the devastation; or it may be that the bronchioles are the first parts affected and the catarrhal proliferation in the alveoli due to an extension of the inflammation from them. The microscope only tells us this: that these grape-like masses consist of intra-bronchial and intra-alveolar products, in a more or less advanced stage of cheesy degeneration.

It is scarcely needful in these days, I suppose, to say much with regard to that distinction laid down by Rokitansky (*op. cit., Syd. Soc. Trans.*, iv. 106) and Skoda (*a*) and followed by numerous writers and teachers, between pneumonia and what they called pulmonary "tubercle;" namely, that the former began, as a rule, at the base; the latter at the apex. Skoda himself narrowed this question very much by begging the larger premiss, and asserting that, pneumonia being an acute affection, and tuberculosis only seldom acute, healthy persons were attacked most often by apicial pneumonia, while any acute apicial infiltration in persons suffering from chronic "tuberculosis" was "tubercular," *i.e.*, phthisical—leading to destruction of lung-tissue. At any rate, from the time of Morgagni downwards to a paper published in 1873 by Schlesinger (*b*) the latest paper I think I have seen on the subject—there are numerous statistics to show that apicial pneumonia is very far from being an uncommon thing. And there is a class of cases to which I think sufficient attention has not been paid, of which the following is an example. For being allowed to examine the case, and for some of the notes, I am indebted to my colleagues, Dr. Broadbent and Dr. Cheadle. I may mention, in passing, that, judging probably from the sharply defined distinctions of books, the house-surgeon who first saw it took it for a case of phthisis: an opinion which in lapse of time, will probably, I think, be justified by the result. A married woman, aged 22, whose father was said to have died of consumption, was admitted into St. Mary's Hospital, having been perfectly well up to a week before, when she complained of pain under her right clavicle. The physical signs were impaired resonance with bronchial breathing at the right apex, and

general bronchits of the smaller tubes. The same night, she was delivered of a six-months' birth. A month later, I examined her. There was no difference on percussion on either side; but, in addition to a general bronchitis which still existed, there was feebler inspiratory murmur at the right apex, as compared with the left.

I have notes of cases similar to this, seen in my out-patient practice—cases which all agree in the presence of a more or less general capillary bronchitis, with localised dulness at the apex of a lung. I have not been able myself as yet to follow out any one of these cases; but in a series of American lectures now being published there is one by Dr. Colwin Ellis on the frequency with which capillary bronchitis is complicated with changes in the air-vesicles, and on its relation to catarrhal pneumonia. In this paper, five cases of the kind I am speaking of are given, two with *post mortem* results. Rindfleisch (*a*) writing on "chronic tuberculosis of the lung," and intending by that name the ordinary form of phthisis we are now considering, supports this view in so far that he places the original seat of his "tubercle-granule" at the passage of the finest bronchi into the air-vesicles, into which its further infiltration proceeds. With the statements of Rindfleisch, Jürgensen, and Buhl, agrees the opinion of Dr. Hughes Bennet (*b*) that in the phthisical process "the bronchi are necessarily involved; their terminal extremities are among the first structures affected"—those parts of the tubes which, says Andral (*c*) "are on the point of froming the air-vesicles."

I have at this present moment under my care at the Victoria Park Hospital two cases in one family which link together in a very interesting way the form of phthisis I have thus slightly sketched and that other form which, exhibiting all the clinical symptoms common to the two classes, does not depend, I think—at any rate, originally—on intra-alveolar changes, but on changes in the walls of the alveoli and bronchi themselves, *i.e.*, on chronic bronchitis and emphysema. Laennec had noticed the strong likeness between his "pulmonary or tubercular phthisis" and this "chronic mucous catarrh"—a common infirmity of old age. (*d*) He says: "There exists, in fact, the most perfect similarity between these two affections, whether it be in the sputa, the emaciation, or all the other symptoms." Of the two cases to which I referred, one is that of a lad aged 16, who presents all the signs of what I am in the habit of calling cheesy pneumonic or broncho-pneumonic phthisis, with, the last time I saw him ten days ago, marked pyrexial symptoms. The other is that of his father, aged 54, who declares that up to last winter—at the very most a year ago—he was perfectly well; while, as to his son, he asserts that, after an attack of scarlet fever, "he was pretty hearty till he catched a cold." The father's father had died at the age of thirty-five from "rupture of a blood-vessel." The two cases stand in strong contrast, yet in strong similarity; the younger dying in no long time from, it may be, the engendered phthisis, "quæ quidem leni catarrhi nomine à miseris istis ægris signari solet; donec tandem negligentiâ incurabilis evadat;' (*e*) the older surviving beyond the life of his son, to wait the close of a chronic and incurable phthisis, "quoniam omnes senes, qui aliquo acuto morbo non corripiuntur, hoc modò phthisicè languentes tandem ultimum claudunt diem" (*f*) It is not true, as Morton seems to have thought, at any rate to some extent, that old age itself is a chronic and incurable phthisis of this kind; but it is true, as he laid down, that the "asthmatic phthisis" of which he writes is marked off from other forms of phthisis by the presence of wheezing and intense dyspnœa throughout the whole course of the disease. I should but waste the time of the College were I to enlarge further on this form of consumption. There is one fact to which I cannot but draw attention; and I think it is important, because it throws some light upon a theory which, for myself, I have utterly discarded: the relation between phthisis—consumption—as with Morton I have defined it, and the presence and development of so-called tubercle. I do not remember to have seen, though I have heard of, cases of old people dying of acute tuberculosis. But, even in those who die in the ordinary course of a chronic bronchitic phthisis, there may be seen scattered round old cavities, or in the neighbourhood of dilated tubes and patches of emphysema, more especially at the bases of the lungs, certain bodies, to the naked eye like miliary tubercles—like well-boiled rice-grains—but under the microscope vesicular lobular pneumonias. The evidence of other observers goes to show, what I have not yet been able to prove to myself, that, in addition to these alveolar proliferations, there are also perivascular products; and in so far I readily accept Dr. Klein's statement with regard to their occurrence in artificial tuberculosis, as probably true also here, that these semitransparent nodules, "due to catarrhal pneumonia, depend on the spreading of the perivascular cords" (*a*), and, to quote Rokiansky again, "are usually secondary processes" (*b*)

But, beyond this, they have no special meaning; they are but the common accompaniments here, as always, of any affection whatsoever of the lungs. The font to which they owe their origin is probably, in these cases, some cheesy focus in some dilated tube: a mechanical process to which the next set of cases may lend at least a possibility.

To be continued.

OPHTHALMOLOGY IN ITS RELATION TO GENERAL SURGERY. (*c*)

By Mr. Brudenell Carter,
Hunterian Professor of Surgery and Pathology to the Royal College of Surgeons.

The subject of the first lecture was "Ophthalmology in its relation to General Surgery." Mr. Carter began by observing that he believed there was no previous example of the office which he held having been conferred upon a surgeon whose hospital and private practice were alike limited to a single department; and that therefore, regarding himself as in some degree a representative of specialism and of specialists, he should hope to be pardoned if he devoted a short time, by way of preface, to the consideration of special practice from the point of view of those who followed it, and to the inquiry within what limits, and for what reasons it should either be fostered or discouraged. He described the problem which he thus stated as one urgently pressing for solution, on the ground that the prevailing tendency to the formation of special hospitals, and special departments of practice, unless it was the legitimate outcome of a division of labour rendered necessary by the progress of science, could not be otherwise than injurious, alike to the profession and the public. He glanced briefly at the popular notions about the necessity or advantage of specialism, and passed in review the state of ophthalmic surgery prior to the invention of the ophthalmoscope, and its rapid development subsequently, dwelling especially upon the tendency to exactness of thought and language which was produced by the exact and minute character of the observations which it became possible to make. He differed absolutely, however, from those who traced the great and sudden progress of ophthalmology to the influence of a division of labour, and attributed this progress mainly to the sudden acquisition of a new and improved method of research. He even went farther, and expressed the opinion that the influence of specialism had been an inju-

(*a*) *Op. cit.*, ii. 60.
(*b*) *Op. cit.*, iv. 83.
(*c*) Abstract of the First of the Hunterian Lectures at the Royal College of Surgeons.

rious one, by reason of its having diminished the number of labourers in the field, and also by its having diminished the opportunities of those labourers to regard the facts before them from a standpoint of general pathology. As an illustration, he referred to the clinical history of optic-nerve atrophy, and showed that the true nature of this affection had been concealed or misunderstood as long as the investigation rested in the hands of specialists, who did not see the cases until impairment of vision became a prominent symptom, and that it was only made clear when physicians, who were not specialists, began to use the ophthalmoscope in the examination of all cases of brain disease. They then discovered the occurrence, as a common precursor of nerve-atrophy, of a swelling of the optic discs which was at first limited to their connective tissue elements, and which, as long as it was so limited, did not at all affect the sight. In the same way, he believed, the discovery of the true nature of many ophthalmic maladies would reward those practitioners who would first accept the ophthalmoscope as an instrument of ordinary diagnosis, to be habitually used without any reference to the state of vision, as a means of inspecting nervous and vascular tissues in the only situation in which they could be seen. He next glanced at the uses of specialism, in conferring manual dexterity and operative experience, and also in leading to the mastery of a great number of details of different degrees of importance, and also at its necessity, as something which supplied an imperative public demand. He did not think, however, that the demand was one which should be conceded blindly, nor without a full consideration of its tendencies and effects, and he therefore proposed to inquire what were the precise claims of ophthalmology upon the attention of the profession. He divided this part of the subject into two heads; first, pointing out that the frequency and variety of the diseases and injuries of the eye were such as to render it certain that every general practitioner would often be called upon to encounter them; and secondly, by calling attention to their great pathological interest and importance, as conditions which allowed a large number of common morbid processes to be watched and studied with an accuracy not attainable elsewhere. In this relation he spoke of the facilities for observing degenerative processes, and also for observing the existence and effects of high arterial tension, which are afforded by the retinal vessels, and quoted Von Graefe with regard to the liability of these vessels, and of the tissues nourished by them, to participate in many constitutional or systemic maladies. He referred to Dr. Wharton Hood's felicitous use of the results produced by iritic adhesions in order to explain analogous results within the large articulations, and then passed on to speak of the light which had been thrown by study of the ocular muscles and of their motor nerves, upon the whole question of muscular paralysis in other regions of the body. Finally, he declared that the diseases of the eye presented, in a concise and legible form, the very alphabet of medicine and surgery, and claimed to have established that the place assigned to them, as matters calling for the attention of students, should be somewhat the same as that which was assigned, by common practice and consent, to the diseases peculiar to women. If they were neglected in the future to the same extent that they had been in the past, he predicted that ophthalmology, cut off from its only proper root in general medicine, would soon languish and decay, and that those who followed it, under such circumstances, being deprived of the stimulus to good work which is afforded by the intelligent appreciation of the profession generally, would be tempted to supply the deficiencies of knowledge by the arts of quackery. He appealed to the rulers of the medical corporations to assist in rendering such a state of things impossible, and to support, by means of the ordinary examinations, the efforts which were now made at all schools of medicine to render instruction in the principles and the details of ophthalmology accessible and sufficient. He announced that the subject of the second lecture would be "Glaucoma."

CASE OF MULTILOCULAR TUMOUR, COMPLICATED WITH PREGNANCY, RUPTURE OF THE CYST, AND PERITONITIS. (a)

By George H. Kidd, M.D.,

President of the Royal College of Surgeons in Ireland; Obstetric Surgeon to the Coombe Hospital.

The case was that of a lady, thirty-eight years of age, who resided in the south of Ireland. He (Dr. Kidd) was asked to see her early in the month of March, and on visiting her he found her confined to bed, the abdomen being exceedingly large, measuring somewhere about forty-four inches in circumference—so large, in fact, that it interfered seriously with respiration, with the heart's action, and with the digestion of food. The lower part of the abdomen, thighs, legs, and feet, were very œdematous. The whole surface of the abdomen was tender to the touch (the patient shrank from having it touched), and her expression was one of great anxiety. She was very much emaciated, and there was a considerable amount of fever, the pulse being about 112. She suffered very much from night sweats, and the urine was loaded with lithates. He was asked to see the lady chiefly to determine whether she was pregnant or not, and if pregnant, he was asked to induce labour. On making an examination, the conclusion he came to was that the greater portion of the abdominal tumour was formed by an ovarian tumour, that there was a large quantity of fluid in the cavity of the peritoneum, and that if she were pregnant it could not be for more than between four and five months. Having arrived at this conclusion, he recommended, instead of inducing labour, that they should in the first instance tap the abdomen which would afford some relief to the constitutional disturbances which she was suffering from, and at all events allow us to arrive at a more complete knowledge of the case, and would also afford time for consideration as to the further steps to be taken. Accordingly he tapped the tumour the day he first saw her, and drew off about five quarts of fluid. The greater portion of this fluid was from the cavity of the peritoneum. It was thin and serous, but a considerable portion of it also came from the ovarian tumour. He tapped first the cavity of the peritoneum, and drew off as much as he could, and he then passed the trocar on into the tumour, and he succeeded in tapping four cysts of multilocular ovarian tumour. After that he was able to trace the outline of the uterus and confirm the opinion that he had already arrived at in consultation on the the case, that the uterus was enlarged to about the fourth or fifth month of pregnancy. He was able to hear the placental murmer, and very faintly a fœtal heart. He could not say with absolute certainty that he heard a fœtal heart, but he believed he heard it. At all events, he felt then in a position to express his opinion that she was pregnant about five months. The result of the tapping was to afford her very great relief. She slept well that night, and was so much relieved, that a week afterwards she was enabled to undergo a railway journey of six hours and come to Dublin. Of course she came with every means that could be used to lessen the fatigue of the journey, and to enable her to bear it, which she did remarkably well. He saw her afterwards and expressed his opinion that the only possible chance for her life was the removal of the tumour, and it was for the purpose of having this done that the lady was brought to Dublin. When she arrived in town he found that she had again so much increased in size that the abdomen was again 44 inches in circumference. It had increased four inches from the time he had tapped her, from the Sunday until Tuesday week following. The breathing was again becoming difficult and oppressed. At this period she was seen by Mr. Spencer Wells, and he took the same view that he (Dr. Kidd) had done, only as to the question of pregnancy, the question of the multilocular ovarian tumour, fluid from the cavity of the peritoneum, and some peritonitis consequent upon it. He suggested as he (Dr. Kidd) had done before that this fluid was from the rupture of one of the cysts of the multilocular tumour. On that Tuesday Mr. Wells again tapped the cavity of the peritoneum, and drew off about five pints of fluid. On the following day he proceeded to operate, and performed the major operation, and to remove the tumour. When the cavity of the abdomen was laid open there came a large quantity of fluid out of the peritoneum, then the pregnant uterus came into view, and after-

(a) Abstract of a communication made to the Dublin Obstetrical Society, specially reported for the Medical Press and Circular.

wards the tumour. Mr. Wells then proceeded to remove the tumour. He found it in an exceedingly soft condition—so friable that it broke down under his hands. There was distinct evidence of recent peritonitis. There were bands of lymph tying coils of the intestine to one another. There was an effusion of the lymph on the parietal surfaces of the peritoneum, and soft adhesions between the abdominal wall and the tumour. However, these adhesions yielded very freely; but the tumour was so soft that it came away, in fact, piecemeal. As there was no possibility of removing it entire, there being some firm adhesions between the omentum and the tumour, it had to be torn away, and portions of the omentum in two places had to be ligatured and cut away. Mr. Wells ligatured these, and round the pedicle he passed a double ligature, drew it tight at each side, cut the ends of the ligature short, and dropped it back into the peritoneum. He then closed up the wound in the ordinary fashion by sutures passing through the whole thickness of the abdominal wall, drawing them into a series of surfaces in contact with one another. The operation took place about twelve o'clock on Wednesday. In the course of the afternoon labour pains set in, and at six o'clock in the evening a five months' fœtus was expelled. Fortunately no hæmorrhage occurred, and there seemed to be no collapse or other inconvenience to the mother on account of the labour. The progress of the case from the day of the operation until the following Sunday was exceedingly favourable. The poor lady herself said that she was more comfortable than she had been for months. The œdema of the abdominal walls and the extremities quite disappeared, and the pulse became lower than it had been for some time before the operation. The temperature varied from 100°, 101°, 102°, on Sunday it was 103°, and ultimately it came down to 99°. Everything seemed so favourable that he (Dr. Kidd) was speaking to a medical friend on the subject on the Sunday after his visit, and he could not help saying to him that he thought she was safe. However, there was fluid accumulating to some degree in the cavity of the abdomen during this time, and in the course of Sunday a quantity of fluid was forced out through the abdominal wound, and the result of this was a considerable amount of collapse. When he saw her he found her very pale and shrunken, and in a state approaching syncope. By giving her stimulants, tightening the binders of the abdomen, and injecting ether she rallied. And while speaking of ether he might say in passing that its effect was not very beneficial in this case. The patient rallied and after a few hours seemed nearly as well as before. The collapse on this occasion seemed to him to be due rather to the sudden removal of the pressure on the abdominal vessels; it was like a patient being tapped with a large trocar in the upright position, and when pressure is taken off, the vessels allow a quantity of blood to accumulate in the *vena cava*. After this there was a sudden discharge of serum from the abdominal wound, and it was evident that this was running the patient down. It was simply debility. However, the constant flow of serum from the abdominal wound and the emptying of the blood-vessels produced this prostration. It occurred to him that perhaps if he could stop the secretion of the fluid it might improve her chance. The idea that presented itself to his mind was that he might inject some iodine into the cavity of the peritoneum, which was, of course, a very serious experiment, but one that he thought advisable. He communicated with Mr. Wells, and decided to support her strength. They gave her as much nourishment as they could, but the prostration continued, and the lady sank and died a week after the operation. He thought this was the first occasion in this country in which ovariotomy had been performed during pregnancy. Mr. Wells in his book gave six cases in which he operated during pregnancy; it was remarkable that in all six the patients recovered. The farther complication in these cases was peritonitis and the rupture of the cyst. That, too, however, was not an unexampled instance, for at the meeting of the British Medical Association at Oxford, a case was detailed where ovariotomy was performed notwithstanding the presence of peritonitis, and then a few hours after the woman was delivered of a full grown child. So that he thought they had sufficient grounds for going on to say that the operation was not prohibited either by the pregnancy or by the existence of peritonitis. This subject he had occasion to bring before the Society at a former meeting. In 1870 the subject of the operation of ovariotomy during pregnancy was under discussion in London, and before 1870 there was a very important paper read by Dr. Playfair on ovarian diseases as complicated with pregnancy. In the discussion which took place at that period, of which Dr. Playfair's paper formed a part, and in which Mr. Wells and Dr. Barnes also took part. He (Dr. Kidd) had the report of his own paper read before this Society in 1870 on "Ovarian Tumour, Complicated Labour," and in the first place he referred to Dr. Playfair's paper, by some of which he thought he showed that Dr. Playfair had collected details of 57 cases, in which he told them that the tumour was pushed down before it into the pelvis in front, presenting an ovarian tumour, and not causing any detriment to the birth of the child. In reference to that subject, he (Dr. Kidd) might mention that he had brought forward a case in which he had succeeded in operating on a tumour of this description, and in which the labour terminated favourably. The question remained whether the labour should be induced with a multilocular cyst or the ovarian tumour removed?

Clinical Records.

CASES IN PRACTICE.

Reported by JOHN W. MARTIN, M.D.,

Assistant-Surgeon, Mayfield Factory Dispensary, Portlaw, &c.

CASE XVI.—*Typhus Fever—Character of the Eruption doubtful in the Commencement—Recovery.*

M. Q., æt. 9, a well-nourished little girl, was attacked March 5th, 1876, with rigors, pains in the limbs, general lassitude, headache, nausea, and vomiting, and other symptoms of general constitutional disturbance. She was seen for the first time March 10th, the fifth day of illness. Her face, neck, and upper portion of the body were covered with an abundant rash, distributed in crescentic-shaped patches, with sound portions of skin between, and presenting features closely simulating the appearances of the rash accompanying an attack of measles. This eruption had appeared on the morning of the 10th, the date of my first visit; accompanying it were intense suffusion of the conjunctivæ, lachrymation, photophobia, and coryza. She complained of a short hard cough, unaccompanied by expectoration; there was no soreness of the throat. Respiration was short and hurried; pulse rapid and weak. Bowels had been well moved two days before my visit. I confess to have been much puzzled by the character of the eruption, its general features and accompanying symptoms favouring the idea of its being the rash of measles. I prescribed the following mixture:—

℞ Liq. amm. acetat., ℥vi.;
Vin. ipecac., ℥ij.;
Syrupi, ℥i.;
Aquæ ad ℥viij. M.

Two tablespoonsful to be taken every fourth hour.

The next day, Saturday, March 11th, sixth day of illness, she was raving constantly, headache very severe, tongue glazed, bowels confined, and only a very scanty supply of high-coloured urine was passed during the preceding 24 hours. The eruption was very dark-looking. Pulse very weak and shabby; in fact, scarcely countable. Respiration very short and shallow, performed entirely by the voluntary muscles. She had not been receiving one-fourth her proper dose of the medicine ordered. I directed the full complement to be given at regular periods, and ordered her feet and abdomen to be well stuped with a strong mixture of mustard and hot water. I also prescribed hyd. c. creta, grs. v., to be given at once. At the evening visit I found her much improved. Pain in the head relieved, tongue moistening; no motion from the bowels; passed an abundance of high-coloured urine free from deposit; and the rash had become much brighter in colour; it had also lost much of its crescentic appearance, taking on the usual characteristics of the typhus rash pure and simple.

Sunday, March 12th, seventh day of illness, she was admitted to hospital. Pulse 148, resp. 52, temp. 104.3.

Tongue moist, great thirst, raving constantly, rash copious over the whole body. Passing plenty of water.

March 13th, eighth day. Had one solid white-coloured motion; tongue moist and coated with a white fur. Free from headache. Respiration laboured, inclined to snoring; no chest complications. Passed over a pint of clear high-coloured urine. Slept well. Pulse 140; resp. 48; temp. 104·1. Mist. acidi sulphurici prescribed.

March, 4th, 9th day.—Doing well. Rash fading from the arms, face, neck, and surface of the chest; still very thick on the hips and lower extremities. Urine a pint, still clear and high-coloured. No motion. Pulse 128; resp. 52; temp. 103·4.

March 16th, 11th day.—Tongue glazed, and typhoid in appearance, brown and dry along the centre and at the tip, white along the edges; abdomen tympanitic; one large white-looking solid motion. Urine a pint and a-half. There were several spots out, over the abdomen and chest, which my father and I thought suspiciously like the "rose spots" of typhoid fever; but we hesitated pronouncing definitely upon them. The typhus rash was fading rapidly from the lower portions of the body. There was no "gargouillement." Pulse 112; resp. 48; temp. 100. Directed a wet compress to be applied to the abdomen, and ordered spirits of turpentine in five drop doses, every fourth hour, and four ounces of wine to be given in the course of the 24 hours.

March 17th, 12th day.—Much improved; tongue moist and cleaning; tympanitis disappearing from the abdomen; had one solid motion; general appearance greatly changed for the better. Pulse 104; temp. 98·4; resp. 44. Water broken.

March 20th, 15th day of illness.—Convalescent. Skin quite clear of eruptive-looking spots; tongue clean; treatment stopped; good nourishment ordered. Pulse 84; resp. 18; temp. 98·4.

The subsequent course of the case was one of steady convalescence.

The following is a tabular statement of the pulse, respiration, and temperature, taken regularly but once a day throughout, at about 12 o'clock each day. Evening temperatures were taken irregularly, and have not been noted. I also regret that accurate notes of the pulse and respiration and temperature for the first two days were not taken and kept.

Day of month.	Day of illness.	Pulse.	Resp.	Temp.
March 12th	7th	148	52	104·3°
„ 13th	8th	140	48	104·1
„ 14th	9th	128	52	103·4
„ 15th	10th	120	40	99·4
„ 16th	11th	112	48	100·
„ 17th	12th	104	44	98·4
„ 18th	13th	100	28	98·4
„ 19th	14th	84	20	98·4
„ 20th	15th	84	18	98·4

The family to which this child belonged was a very large one, consequently there was some overcrowding in the sleeping apartments. The house itself, with beds and bed-linen, were, all things considered, as well and cleanly kept as could be expected. The rooms were well whitewashed, and the state of the yard in the rear was satisfactory. I am convinced that the true source from whence this patient contracted the disease was the woman who was acting as help and general servant. She was the wife of a pensioner, who died some four or five weeks before the commencement of this girl's illness, from a most virulent attack of typhus, one of the worst cases I have seen for a long time. In the same house in which this man died, two other very severe cases of this fever occurred, in the persons of the occupier and his wife, both of whom were removed to hospital and recovered. After her husband's death, this woman left the village for a fortnight or more, then returned, and was a week or ten days in service before my patient showed the first symptoms of being affected. After removing the little girl to hospital, the following sanitary measures were observed: The straw in the bed was taken out and burned. The bed-clothes were steeped in boiling water for some time. A plate of chloride of lime and sulphuric acid mixed was placed in the room; the window and door were then closed, and the fumes from the mixture were allowed to fill the room for over two hours. At the expiration of this time the window and door were opened, the plate removed, and free access of air was permitted for the next 24 hours. The walls were then well whitewashed, and the room re-occupied. Since then no other case has occurred in this house.

Transactions of Societies.

DUBLIN OBSTETRICAL SOCIETY.

THE concluding meeting of the session was held on Saturday, June 10, 1876, the President, Dr. LOMBE ATTHILL, in the chair.

The PRESIDENT (Dr. More Madden, Vice-President, being in the chair) exhibited a recent specimen of an ovarian cyst which had been removed from a patient in the Rotundo Hospital on the previous Tuesday.

Dr. MORE MADDEN thought the Society owed the President its thanks for the details he had given of the interesting case, and still more for the candour and courage with which he had come forward and detailed the circumstances of an unsuccessful case—a candour which, if more frequently imitated, would lead to better results in medical statistics at large. As the President was willing that there should be a discussion on the communication, he (Dr. More Madden) had no douht that some of those present (who like himself had had the opportunity of witnessing the skill which the President exhibited in the operation in question) would be happy to bear testimony to the ability with which the case was treated, notwithstanding its unfavourable termination.

The PRESIDENT intimated that as the next business on the paper was the adjourned discussion on Dr. Kidd's case of "Ovarian Disease (Multilocular Tumour) complicated with Pregnancy, Rupture of a Cyst, and Peritonitis" (communicated at the April meeting of the Society), it would be better that the discussion on that paper should now proceed, and the two cases could be dealt with at the same time.

At the request of Dr. Denham,

Dr. KIDD gave a brief *résumé* of the chief points touched on in his communication, which will be found on page 525.

Dr. DENHAM said he would be very slow to operate on pregnant women with ovarian tumours, and he generally preferred waiting until the result of the pregnancy had been attained, and then when the proper time arrived—if it was thought right—that would be the suitable time for operative interference. The whole subject was so fraught with interest that one scarcely knew where to commence in dealing with it. The whole question involved was the propriety of the operation. He felt that the subject was so important, that it was difficult to discuss it with calmness. Baker Brown, one of the first operators in the world, had nine cases of ovariotomy, seven of which were fatal. Only two, therefore, recovered, and he was so shocked with the result that he ceased to operate altogether. Mr. Bird also, a very able surgeon, had operated on thirteen cases, but the mortality was so great, that he either ceased to record his cases, or he ceased to operate altogether. There might be something in the atmosphere of this country; but he believed Mr. Spencer Wells had come over to Ireland on five different occasions to operate, and four of the patients died. He knew that Mr. Spencer Wells' operations in this country had been anything but successful.

Dr. GEORGE JOHNSTON said he had not had much experience of ovariotomy, never having performed the operation. In cases such as the President had described he did not think he would be justified in operating. At the time that patient first came to the Rotundo Hospital it was considered that it would not be justifiable to operate on her, inasmuch as she was in good health and suffering no pain, the only inconvenience she suffered from being her large size. It could be distinctly diagnosed that the case was one of unilocular tumour, and the result of the tapping showed that the diagnosis was a correct one. He must say that he would have been very tenacious about operating in that case. With regard to the

early operation he did not consider that it would be at all prudent that they should do so. He had a case under his observation at present which showed this. The patient was still in good health, and it was now nearly 18 years since she first came under his notice. He had got the late Dr. Johnston to see her, and he wisely said, with his characteristic bluntness, "There is just one little remedy that will be of great use in this case, and it is a very valuable one; It is the "tincture of time.'" (A laugh.) That lady was actually smaller now than she was at that time. He had another case—it was one of fibroid tumour—and that patient either had not very much increased in size, and she enjoyed good health. She was of very large size, and she had had the opinion of several, and they did not consider it prudent to attempt to operate. At any rate, the patient was surviving it. He did not wish to say anything further on the subject, except that he would be rather tenacious in operating in these cases unless he saw that really the case was an urgent one, where the patient was suffering extreme pain, and that there was a tendency to an evil result.

Dr. McSwiney thought it would be greatly to be regretted if the operation of ovariotomy were to be discredited by any discussion in that Society. Persons who, like himself, had no experience from personal performance of the operation, but only knew the records as they were to be found in the literature of the subject, could not all coincide in the opinion that it is an operation that should not be had recourse to. On the contrary, as it appeared to him, the records of the operation of ovariotomy clearly demonstrated that when it was performed on those occasions when, he presumed, the skill of the obstetric surgeon alone recommended it to be performed—occasions when it appears probable that the life of the woman would be the forfeit of not performing the operation—that on such suitable occasions the results have been in the highest degree satisfactory. He took it that it was not an operation that was performed merely because it *might* result in the safety of the woman, but an operation performed when, humanly speaking, there seems to be no chance of the woman surviving unless relieved of this tumour; and although there might be something in the atmosphere of Ireland to render the cases peculiarly fatal (a laugh), still he thought they were bound to admit that there had been many successful operations in this country. He was not prepared with the statistics, but he was aware that there were some members of the Society present who had had successful cases, and he had the great satisfaction and pleasure of seeing two successful cases—one an operation at which he was present, and the other he saw prior to the operation, both of these operations being performed by the President of the Society, and both resulted in the recovery of the patients. He (Dr. MacSwiney) would venture to raise his voice against any attempt to discard the operation of ovariotomy in suitable cases.

The President said the discussion had taken two aspects—1st, as to the advisability of operating during pregnancy, and 2nd, as to the justifiability of ovariotomy at all. As to the first aspect, that was one of the most difficult questions which he thought the obstetric surgeon could be called upon to decide. It fell to his lot within the past week to decide on that question. A patient was sent to him with a well-marked ovarian tumour. She was also, he believed, pregnant some eight or ten weeks—at least, so he believed—but at that period of pregnancy, with a large ovarian tumour in front, it was out of his power to say definitely whether the patient was pregnant or not. He believed in that case it was his duty to wait and see what effect pregnancy and the co-existence of the tumour would have, and certainly unless grave symptoms arose he, did not intend to interfere in that case; but it was exceedingly probable that he might be compelled either to tap her or have recourse to the operotion. He, however, certainly thought that he ought to wait, and not perform ovariotomy on a pregnant woman unless the symptoms demanded it. He thought that those were the views of Dr. Kidd and Mr. Spencer Wells. Dr. Kidd's case was one that must have terminated fatally if left alone. With regard to the question of whether ovariotomy was justifiable or not, he did think that the statistics of Mr. Spencer Wells were sufficient justification of the operation. Mr. Spencer Wells' mortality did not exceed 20 per cent. in a list of 100 case, and Mr. Keith, of Edinburgh, in 50 cases, had only 8 deaths. He (the President) did not think the air of Ireland had anything to say to the success or non-success of the operation; he thought some of the causes of the latter result were preventable. His own very limited experience was such that he did not put himself forward as an authority at all. He had, however, had the good fortune to save two patients. One of those patients would certainly, in his opinion, have been dead months ago if it were not for the operation. The other woman, though actually not dying, still had a rapidly increasing tumour, and he thought her end would have been as the average of those had been. With reference to the case he had detailed that evening, he had no hesitation in saying that he believed he was justified in the performance of the operation. This was a woman who measured round the waist not much under two yards, was quite unable to walk with any degree of comfort, and whose size was rapidly increasing. When she was tapped in the Rotundo Hospital some months ago, in the course of four weeks the tumour was distended, and the large amount of twenty-one quarts had been removed. He wondered how long the woman would have losted after the removal of twenty quarts of fluid every three months. He had before him the results of 500 cases tapped by Mr. Spencer Wells, and the mortality of those cases was 25 per cent.—a mortality greater than that which was the average of the operation of ovariotomy. Allusion had been made to the *éclat* of the operation and the temptation of large fees. He did not think any thing could be more discreditable to a medical man than the performing of the operation for the mere question of *éclat*. He did not think there was one member of the Society who would operate in an improper case for the sake of *éclat*. He (the President) had been asked to operate twice within the last three years, and he refused, because he saw that the cases would in all probability terminate fatally. On the other hand, nothing would ever deter him from performing an operation that he believed himself called upon to perform with the view of saving a life which otherwise must perish.

Dr. Kidd, in the course of his reply, said that the discussion had taken a turn which had surprised him very much indeed. How they should go back to discuss the propriety of ovariotomy at all—he could not understand. If there was any question in surgery which could be proved to demonstration, he believed it was the propriety, and not only the propriety, but the absolute duty, of the surgeon to perform ovariotomy. Mr. Wells said in his book that he was brought to see a patient by one of the leading physicians in London, who spoke to him about the risks of the operation, and as to how any man could dare to undertake the operation. The reply he received was, how could any man dare "to leave the poor woman to die without an effort to save her?" And he (Dr. Kidd) believed that was the more important question when they remembered that the average duration of life in cases of ovarian tumour was under two years. It was the most painful death perhaps that one ever witnessed. He thought there were very few surgeons of the present day who did not recognise the propriety of this operation; but at the same time he quite concurred with Dr. Denham and Dr. Johnston that there were many cases in which the operation should not be attempted, He had himself declined to perform ovariotomy in a case in which another surgeon in Dublin operated upon the patient, and successfully. In that case the woman gave him (Dr. Kidd) a history of having had a tumour for fourteen years, and even after that time it was not a large tumour. Its rate of growth was not great, and her health was not bad, and in consequence he strongly advised that there should be no operation. However, the woman went into another hospital, and in a few days he was present, and saw the tumour removed. He must say that he thought in that case the operation entailed an amount of risk that he would not recommend a patient to undergo. He had seen many other cases where he had advised the patients not to undergo the operation, the health not being seriously injured by the tumour, which was not rapidly growing. There were certain cases where an ovarian tumour might go on for a number of years without imperiling the patient's life, and in those cases the operation should not be performed. But if a tumour were rapidly growing and a woman's health suffering, then he said that it was evidently going to run her into her grave within a few months, and he did not hesitate in such a case to recommend the operation; but it was an operation that he thought should not be undertaken without the patient's being made fully aware of the risk she incurs by its performance, and she herself must decide as to whether she will risk a few months of life and suffering against the prospect of perfect recovery, and it was to be re-

membered that recovery in these cases was perfect recovery. That was a very important point. A woman, if she recovered after the operation, might enter into all the relations of life. But the case which formed the subject of his communication, was as to the operation taking place during pregnancy. Now Dr. Denham had spoken about the risk of abortion coming on after the operation, and had recommended that the operation should be postponed until after the termination of pregnancy. He quite agreed with Dr. Denham with regard to that, and that was the point that he (Dr. Kidd) brought before the Society so long ago as 1870. If the case were one of multilocular cyst, and that they could not reduce the size of the tumour by tapping, the risk in that case was very much greater. But if in addition to that they had a case of multilocular cyst, and that the tumour had ruptured, the contents escaped into the peritoneum, and the woman would die in a few days, probably, and they knew in similar cases that the operation had been performed and the patients had lived, surely it was their duty to recommend the operation? That was the first case recorded where an abortion took place after the operation, and in all the other cases the patients went on to their full term of pregnancy after the operation. Dr. Johnston had spoken of cases running on for 18 years, and he had also referred to cases of fibroids. Cases of ovarian diseases that run on for 18 years are exceedingly rare. He believed that in many of those cases of very prolonged duration that there had been an error in diagnosis. He did not say that with regard to Dr. Johnston's cases, but it was very doubtful whether they were cases of ovarian tumours. If they were subperitoneal fibroid tumours, he did not think they should be operated upon. That, however, did not involve the question of ovarian tumours. The President had alluded to a case of pregnancy of 8 or 10 weeks. He (Dr. Kidd) could scarcely imagine the question of ovariotomy arising in that case, unless the ovarian tumour was in a condition requiring operation. If it was a case of 8 or 10 weeks' pregnancy, and if the ovarian tumour did not require the operation, he did not think they should interfere, and in that case he would prefer the chance of inducing abortion to attempting the operation, if he saw there was necessity for it. The object of his paper in 1870 was to show that in a number of cases they might have pregnancy run on perfectly safely and well to the full term, notwithstanding the presence of the ovarian tumour, and his paper was drawn forth by the remark of Dr. Barnes, that it was impossible for an ovarian tumour and a pregnant uterus to exist in combination.

Dr. JOHN A. BYRNE then detailed the history of a very interesting case, a sequel to one which he had brought before the Society at a previous meeting, He gave a brief *résumé* of the former case, which had occurred in his practice. The woman was pregnant of her second child; her first child, a male, was delivered by cephalotripsy, the forceps having been tried by him and Dr. Kidd, who assisted him, without success. On examination by himself and Dr. Kidd, it was ascertained that the conjugate diameter was somewhat less than three inches. He recommended to her to have premature labour brought on if she again became pregnant at the end of the seventh month of gestation. He accordingly at the expiration of that time induced premature labour by the use of Dr. Barnes' hydrostatic dilators, and when the os uteri was fully dilated, he performed version by the bipolar combined method as recommended by Dr. Braxton Hicks. The child, a female, was born alive, and lived six hours. Dr. Byrne recommended in the strongest manner the adoption in suitable cases of Dr. Braxton Hick's plan to the members of the Society, and he illustrated by drawings the different stages of the operation. This patient again became pregnant, and on the 204th day labour came on spontaneously, and a male child was born, which presented by the feet; the child lived six weeks, and eventually died from bronchitis. Dr. Byrne dwelt upon the singularity of the phenomenon of the uterus taking on expulsive spontaneous action at the same period exactly in a labour subsequent to that in which he had induced it by operative means; he also discussed at some length the proper mode of treatment in those cases where we are certain from measurment and the history of previous labours that the conjugate diameter is narrowed, and concluded a very interesting and really practical paper by recommending that labour should be induced and version be performed, thereby giving a chance of life to the child, rather than resort to the dreadful alternative of craniotomy, after the unsuccessful application of the forceps, in those cases where the conjugate diameter was somewhat less than three inches.

Dr. KIDD, after corroborating the facts contained in Dr. Byrne's description of the case, thought if they had experience of a previous difficult labour, and they were quite satisfied that they had a small pelvis, it was a great deal safer for both mother and child to induce labour at the seventh month.

Dr. DENHAM considered inducing labour at the seventh month in such cases as the one described by Dr. Byrne an excellent practice, the chances for the safety of the mother being greater, and he believed the chances for the child were tenfold.

The PRESIDENT showed one of the largest intra-uterine polypi he had yet removed. Its substance was not dense, but its thickness was so great that on attempting to use the écraseur the resistance was something tremendous. It was removed from a married woman aged 38 years, who had never been pregnant. She suffered from profuse menorrhagia—so profuse that menstruation became almost continuous. She was in good health up to four years ago. She was at the time of the operation in the most anæmic condition in which he ever saw a patient.

The Society then adjourned until next session.

MEDICAL MICROSCOPICAL SOCIETY OF LONDON.

AT the last meeting of the Society, MR. NEEDHAM communicated the particulars of a case of

SCIRRHOSIS OF LIVER IN A CHILD

and showed specimens both of the liver and other organs. The child, æt. six years, was admitted as a patient in the North-Eastern Hospital, Hackney Road, on June 23, 1875. Her antecedents were good, and the child's health had never suffered till lately, when she was observed to be losing flesh, and six days before admission her abdomen began to swell. She had always been well taken care of, and had never taken spirits in any form. In July the abdomen was tapped, but soon again refilled. 42 oz. of fluid were removed. The child rallied and returned home, but was re-admitted in December, 1875, much worse, and suffering from attacks of epistaxis and hæmatemosis; and in January, 1876, she died in convulsions, after having vomited a quantity of coffee-ground material.

Post-mortem examination showed the liver to be "hob-nailed," indurated, and weighing 19½ oz. It was uniformly straw coloured, no puckering of Glisson's capsule, and a section appeared fleshy, intersected with bands of a tough material. Spleen firm; 6 oz. in weight. Other organs healthy but anæmic. Stomach contained food and streaks of blood; but the source of the hæmatemesis could not be found.

A section of the liver showed with the microscope liver structure cut off into island glands of connective tissue, in which were elongated cells that readily were stained with carmine; and besides these, dotted about, and easily stained, were very many round cells, like white blood-corpuscles, to which they seemed more related than to the long cells above mentioned. The liver-cells were often confused by this new growth, and were undergoing fatty degeneration in some places. Glisson's capsule was healthy, and had taken no part in the process. The kidneys showed proliferation of connective tissue, as did also the spleen; and between the gastric tubes in the stomach was much of the small cell growth such as was seen in the liver.

The various organs have been prepared with chromate of ammonium and also with spirit, and had been stained in various ways; but the same appearances always presented themselves. In between the muscular fibres of the heart, and in the brain, especially about the blood-vessels, the same small cell growth could be well seen.

Dr. PAYNE had never heard of a case where the changes were so universal. Similar conditions in the stomach and kidney had been before described, but never, as far as he was aware, in the heart; it would be extremely interesting if scirrhosis of the liver could be made a general disease. He had also seen a case of scirrhosis of the liver at the age of four years.

Dr. PRITCHARD suggested the presence of the small cells in the various organs pointed only to some nutation of the blood-vessels, and to no particular diseased condition.

Mr. NEEDHAM, in reply, stated that in another case of scirrhosis that he had examined he had found all the changes here described. The proliferation of small cells was equally around arteries and veins.

The session will wind up on Friday the 30th, with a *conversazione* at 6 Pall Mall Place.

METEOROLOGICAL SOCIETY OF GREAT BRITAIN.

At the last meeting of the Society, June 21st, a paper was read by Mr. F. Shaw on

THE CLIMATE OF SCARBOROUGH,

of which the following is an abstract.

Scarborough is situated in Lat. 54° 17′ N., Long. 0° 23″ W., on the North-East coast of England, and contains a resident population of about 27,000. The thermometers used were placed in a louvre boarded case, fixed to the north side of a stout wooden structure, having an open grass plot in front of them. The garden is about midway between the north and south sides of the town, and about 150 yards from the shore, and as both residents and visitors are continually passing along this line, the observations may be taken as fairly representing the temperature of Scarborough as a watering place. The mean monthly temperatures, based on an average of eight years ending 1875, are as follows :—

Jan. 38 8°	Apr. 46.6°	July 60.4°	Oct. 48.2°
Feb. 39.7°	May. 50.5°	Aug. 58.9°	Nov. 42.2°
Mar. 41.6°	June 55.9°	Sep. 55.1°	Dec. 39.0°

Mean for the year—48.1°.

The maximum temperature on any day in July, the warmest month, does not exceed on the average 78.0°, the highest in the eight years being 85.5°, which occurred in 1868. The mean of the monthly minimum readings in January, the coldest month, is 24.2°, the lowest during the whole period being 13.3°, on Jan. 1st., 1875. The moderate and agreeable summer temperature is due to the close proximity of the town to the ocean, which, in the warmest month of this season, is about 5° below the air. Another noticeable fact is, that in hot weather, with a tolerably clear sky and a temperature between 8 and 9 a.m of 60°, rising to a maximum of nearly 70°, the wind which in the morning is blowing from the S.W., or W.S.W., generally backs to the S.S.E. by the middle of the day, bringing in a cool, refreshing breeze from the sea; it however gradually resumes its normal S.W. direction during the night. The autumn and winter temperature are also much influenced by the sea on the one hand, and the shelter afforded by the surrounding hills on the other. The sea is about 5° warmer than the air in the autumn, and 32 in the winter, whilst the prevailing winds are south-westerly, and not felt in their full force. The annual rainfall, on the average of the last ten years, is 28.29 inches, which falls on 167 days.

Vital Statistics.—From the Registrar-General's return we earn that during last week 5,317 births and 3,253 deaths were registered in London, and twenty-two other large towns of the United Kingdom. The mortality from all causes was at the average rate of 24 deaths annually in every 1000 persons living. The annual death-rate was 20 per 1000 in Edinburgh, 19 in London, 28 in Glasgow, and 26 in Dublin. The annual rates of mortality during the same period in the other large towns were—Norwich 18, Hull 20, Leicester 14, Portsmouth 21, Newcastle-upon-Tyne 19, Birmingham 20, Brighton 22, Leeds 21, Wolverhampton 21, Bradford 26, Sheffield 21, Plymouth 26, Bristol 19, Oldham 24, Manchester 27, Salford 23, Nottingham 21, Sunderland 17, and Liverpool 22. The annual death-rate from the seven principal zymotic diseases averaged 2·9 per 1000 in these towns, and ranged from 0·6 and 1·0 in Norwich and Sunderland, to 7 5 and 8·0 in Portsmouth and Plymouth. Scarlet fever continues fatally prevalent in Portsmouth, and measles both in Plymouth and Portsmouth ; it is much on the decline in London, 33 deaths only having occurred last week. In Manchester and Salford, 11 deaths were referred to small-pox ; since the beginning of the year 242 fatal cases of this disease have been recorded within those two municipalities, in addition to 75 in the Monsall Hospital, which is situated outside the city of Manchester. The fatal cases of small-pox in Liverpool were 15, against 2 and 11 in the two preceding weeks. Two deaths only from small-pox were registered in London.

Hospital for Diseases of the Throat.—On Wednesday last the biennial festival of this institution was held at Willis's Rooms, St. James's, under the presidency of Earl Cowper, who made an earnest appeal for funds to enable the committee to proceed with the new building of which they stood so much in need. Before separating subscriptions were announced from those present amounting to £1,490.

REGISTERED FOR TRANSMISSION ABROAD.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, JUNE 28, 1876.

VIVISECTION.

LIFE is short, art long, opportunity fleeting, experiment slippery, judgment difficult. These are the first words of the aphorisms of Hippocrates, inscribed on the porch of the Temple of Healing, and they are likely to have a new meaning conferred upon them should the Cruelty to Animals Bill, introduced into the House of Lords by Lord Carnarvon, unfortunately become law. That measure will certainly make experiment more than ever slippery, and in so doing it cannot fail to enhance the difficulty of judgment, and to postpone that curtailment of art and prolongation of life, towards which science and benevolence have been recently striving with vigour and with sanguine expectation. "A great scientific revival," said Lord Cardwell, quoting one of the witnesses before the Royal Commission on Vivisection, "is going on," or more properly speaking, "has begun in this country." That we are on the eve of important discoveries in physiology and pathology will be acknowledged by all who can discern the signs of the times. In respect of the nature and habits of contagium, the actions of remedies, the functions of the nerve centres, we are justified in looking for revelations that will circumscribe and perhaps abolish some of the worst scourges of our race ; that will wipe away much misery and suffering, and help us to solve some difficult problems in education and sociology. But this fair prospect must be abandoned if Lord Carnarvon's project is to be adopted. The measure for which he is responsible is really a bill to put down physiological and medical research and to cripple

physiological teaching. Free thought, and free trade, and a free breakfast table are amongst our most cherished privileges, but free science is apparently not to be tolerated, and so our Colonial Secretary applies himself with inquisitorial rancour to retard human progress, and to secure to our children the entail of many of the ills that afflict us. It is as well that we should realise the fact that the *odium theologicum* has played no small part in the agitation that has been carried on against vivisection, and that a foolish jealousy of science, and of its encroachments upon the domain of ignorance has, in some degree, instigated the attack that has been made upon the students of biology in a quarter in which popular passion and prejudice are easily stirred. The anti-vivisection phalanx, led on by the incomparable Jesse, is composed of enthusiasts, crotchet-mongers, and puzzle-brains in about equal proportions. In its rear may be discerned a few worthy men who have not narrowly examined the subject, and who have vivid imaginations or keen sympathies.

That the effect of Lord Carnarvon's Act will be to interrupt all physiological investigations in Great Britain will scarcely be doubted by any one who has glanced at it even cursorily. That that is its set purpose, in spite of all appearances to the contrary, will be admitted by any one who has examined its provisions minutely. Why the very title of the Act at once makes plain its animus. Instead of being described as an Act to regulate vivisection or painful experiments upon living animals, it is called the Cruelty to Animals Act, an act to prevent cruel experiments upon animals. Although the Royal Commissioners on Vivisection failed to obtain any evidence that cruel experiments, *i.e.*, experiments in which pain is wantonly inflicted, have been practised in this country, the Act evidently assumes that such experiments are of frequent occurrence, and proceeds to legislate for their prevention with a zeal as great as was displayed when epidemics of garrotting and kicking called for special interference. It prohibits such experiments and all experiments upon living animals calculated to give pain, except under restrictions of the most vexatious nature, and it punishes by fine or imprisonment any one setting at nought that prohibition. The investigator, forsooth, who henceforth desires to interrogate animated nature must only do so in a registered place, subject to inspection, and after he has received a Secretary of State's licence, which may be revoked at any moment without reason or redress, and which may have attached to it any conditions which the Secretary of State may think fit, and which may, of course, be of such a character as to render the licence practically useless. Not only so, but before obtaining a licence, he must show that his experiments will tend by new discovery of knowledge to save or prolong human life or alleviate human suffering, a provision which, according as it is freely or stringently interpreted, may cover or exclude all possible experiments. Then the investigator is to be watched at his work, to ensure that he employs anæsthetics from first to last, and that he kills the animal when the experiment is over. He is not to be permitted to demonstrate his results to his professional brethren or pupils, nor to repeat any experiment which he may formerly have tried with success. When he is once known as a vivisector, even although he has not renewed his licence, he is liable to have his house searched at any time by a policeman on the motion of any suspicious neighbour, and if he resists this intrusion he is again mulcted in a fine. Experiments without anæsthetics or protracted after the effect of the anæsthetic has worn off, or that are essential as class illustrations or as confirmation of previous discoveries, may be sanctioned under certificates signed by the President of the Royal Society or of one of the Colleges of Physicians or Surgeons, and a professor of physiology, medicine, anatomy, or surgery, but such certificate may be at any time disallowed or suspended by the Secretary of State.

It cannot be necessary to enumerate other indignities and hardships to which this Bill would subject our scientific explorers, for it must be clear that these already referred to are sufficiently intolerable to put a period to scientific exploration in the department of physiology in these kingdoms. Our physiologists will not with arduous labour and self-sacrifice pursue researches that can only be carried on by means that this act makes odious. They will not submit to harassing limitations and interference, or to be branded as licensed vivisectors, and thus be associated with licensed victuallers. They will not expose themselves to the risk of having to defend their proceedings in a police-court, or to expiate their discoveries in the House of Correction. We speak not without authority when we assert that in the event of this Bill becoming law, some of our physiologists will withdraw to other countries where unctuous sentimentality is not so powerful as it is with us, and their exodus will be a perpetual disgrace in the history of England of the nineteenth century, whilst others will abandon physiology and devote themselves to other departments of medicine which are likely to be more remunerative to them, if not to mankind. Italy is at this moment strenuously endeavouring to induce Schiff, the Arch-Vivisector of the age, to remain with her, and to postpone his proposed return to Germany. England is about to banish all physiologists from her shores.

But Lord Carnarvon's Act is not only bad in spirit, but contemptible in execution, so much so indeed as to be occasionally unintelligible. It is pervaded by that reckless carelessness that has been denounced by judges and other eminent legal authorities as a discreditable and perplexing characteristic of so many modern statutes. It is presumptuous, when it declares that curari is not an anæsthetic, and glaringly defective in that it affords no definition of its most momentous terms. It does not define an anæsthetic, nor enumerate the agents that may be used as anæsthetics, so that we are left in doubt as to whether morphia, codeia, aconite, croton, chloral, and a score of other agents that might be named, are included in that class. It does not define an animal, but is all-embracing, as the Duke of Somerset sagaciously pointed out, so that after it has received the Royal assent the unlicensed microscopist who crushes a diatome or boils a bacterium will be liable to condign punishment. It does not define pain, nor provide any test by which its presence may be determined; and this is no mere quibble or frivolous objection, for as *painful* as distinguished from *painless* experiments are dealt with by the Act, we are entitled to know how we shall recognise that superadded quality which shall bring an experiment within its mean-

ing. If mere struggling and contortions are to be the measure of pain, then we must believe that a decapitated animal is more sensitive than one with its head on; while if cries are to be its guage, then we may as well dispense with anæsthetics, for a rabbit profoundly unconscious from the effects of chloral cries more piteously when its tail is pinched than an unanæsthetised rabbit does during the amputation of a limb. The Act, indeed, is entirely vitiated by the omission of any indication of what is meant by an experiment calculated to produce pain, and this omission common sense—that refuge of common fools—cannot supply. Is the administration of a drug to an animal an experiment calculated to produce pain? It would seem so, for the 12th section provides that a judge may sanction experiments upon living animals when he is satisfied that it is essential for the purposes of justice in a criminal case that such experiments should be performed. As experiments to aid the purposes of justice can only be required in cases of suspected poisoning, and as special sanction is necessary for such experiments, it is evident that the Act contemplates and forbids the experimental administration of drugs to animals. If it is necessary to be in possession of a licence or judge's order before administering opium, or belladonna, or Calabar bean to an animal, it is of course requisite to be protected in a similar manner before administering experimentally ether, chloroform, or other anæsthetics, so that the Act includes amongst the experiments calculated to cause pain the very practice which it enjoins with a view to the abolition of pain. A physician has lately been administering daily small doses of absolute alcohol to a number of young animals, with the view of determining accurately the effect of alcohol upon nutrition and development. These experiments have certainly been calculated to produce pain, as the alcohol has had to be given by force and as several of the animals have died in convulsions influenced by it. Such experiments unauthorised will therefore after the passing of this Act become illegal, and the physician will be liable to punishment for doing what dog-fanciers have done with impunity for generations to correct the growth of their pets, and what they will probably continue to do for generations to come. But of course dog-fanciers are an influential fraternity! Lord Shaftesbury cannot fail to be aware of the fact that the volume of pain endured by any one pack of fox-hounds in this country in their training and discipline in the course of twelve months is infinitely greater than that suffered by all the animals subjected to vivisection in the same period. But then fox-hunting is a noble sport, and the fox, an animal somewhat larger than a common cat, as we all very well know, keenly enjoys being pursued and torn in pieces, and having his tail cut off. It is remarkable that the fox has not been specially exempted from vivisection, and the pigeon, too, that is so largely in demand at Hurlingham. The apotheosis of the dog has been accomplished—why should not a few wild animals be made sacred also? It is enough, to use Mr. Ruskin's formulary, to make a man wish himself a dog, or a fly, or even a black-beetle! The dog and cat are, with the rabbit and guinea-pig, almost the only animals that are available to the physiologist for his experiments, and the higher differentiation of their structure and functions renders certain classes of experiments possible in them that would be impossible in the rabbit and guinea-pig. The exemption, therefore, from experiments extended to them by Lord Carnarvon, at the dictation of the Editor of the *Spectator*, is equivalent to the total abolition of two-thirds of vivisection as practised in this country.

So wholly unwise and objectionable is the Act before us that it is scarcely worth while to criticise it in detail, It ought to be opposed in its entirety, or to be subjected to amendments so considerable as to amount to complete reconstruction. One or two, however, of its worst features may be referred to first to illustrate its general tendency. It provides that inspectors are to be appointed by the Secretary of State, and that they are to visit from time to time all places registered for experiments, and it is in keeping with the slovenliness of the measure that it does not further specify the duties to be performed by these inspectors, nor require of them any particular qualifications for their office. It would be open to the Secretary of State under the 10th clause, to nominate as inspectors, naval or military officers, excisemen or even letter carriers, or to select for supervision over physiologists, men of the class whence the Society for the Prevention of Cruelty to Animals derives its officials; some of whom have been convicted of having trumped up accusations in order to extort money. Those who practice vivisection have no reason to shrink from inspection; many of them desire it and have asked for it, but surely they are justified in demanding that the inspection shall be conducted with intelligence, fairness, and competent knowledge. No one but a medical man is capable of appreciating the nature and drift of an experiment upon a living animal or of saying whether or not it is accompanied by pain.

Then, again, this Act orders that the results of all experiments upon living animals shall be reported to the Secretary of State, by whom they shall be utilised for the public good. It is designed that the Secretary of State shall become a great scientific luminary, and that physiogists, pathologists, and therapeucists, shall in future have no property in, nor credit for, their own discoveries. When their modest confiscation is accomplished, he who is afflicted by toothache, or any other variety of human suffering, will only have to write to the Secretary of State, enclosing a stamped envelope, in order to be put in possession of the very newest method of alleviation.

We have at present neither heart nor patience to expose more of the weakness and absurdity of the Cruelty to Animals Act that is now under the consideration of the House of Lords. An uncompromising opposition ought to be offered to it by the medical profession. If it cannot be defeated—and as a Government measure it will command much blind support—it may be at least modified in such a manner, as to make it not altogether and absolutely prohibitive of physiological research in this country.

To find an ex-premier casting doubts upon vaccination, and a minister of Lord Carnarvon's supposed enlightenment introducing a measure of this kind, is enough to make one ashamed of his country. This Bill will undoubtedly make England the laughing stock of scientific Europe.

THE METROPOLITAN HOSPITAL SUNDAY FUND.

We may, we believe, fairly congratulate the Committee of the Hospital Sunday Fund on the success of this year's collection. Up to the time of our going to press, the sum paid into the Mansion House, exceeded £22,000. This is a larger sum than that received in the same number of days, last year. The collection is such an one, as will justify the anticipation that this year's total will be higher than in any former occasion; although, with our lay contemporaries, we feel sure that the whole sum will not be as large as it ought to be. However much Londoners may pride themselves in supporting their great hospitals, they must be judged to have done far too little for them, and nothing by comparison with what is actually done by the gratuitous services so freely given by the profession. The vivisection agitation may possibly have done something to check the flow of charity, for here and there we hear of a minister having refused to join in the collection, least he should thereby give some indirect or vert encouragment to the alleged practice of vivisection. The vicar of a large parish in the North-West of London has even accused the Council of the Fund, of "ostensibly collecting money for the benefit of the poor, and actually appropriating it to the purchase of animals for vivisection purposes; in other words for the instruction of medical students in physiological cruelty." It would be useless to attempt the task of convincing a man of this stamp of the baseless injustice of his argument; he is evidently wanting in the promptings of a charitable heart, and although "one rose from the dead," he would probably refuse to admit that those who are foremost in all good work and in the alleviation of pain and sickness, are incapable of the acts of cruelty laid to their charge. Another instance of perverseness has come to our knowledge in the case of an incumbent of a church in that fashionable quarter, Pimlico, who, availing himself of all the effective machinery put into motion by the Committee of the Hospital Sunday Fund, preaches a sermon and collects a considerable sum, which he has since determined to hand over to some pet institution far away from London. This will, we fear, appear to common-place illogical minds as a case of misappropriation. On the whole, however, the clergy and ministers of all denominations, have done their work nobly and with a heartiness beyond all praise, and although there have hitherto been grumblings against the Distribution Committee, this body cannot go far wrong, as they are not only guided by fixed rules laid down for them by those who elect them, but are also governed by an earnest desire o act justly and kindly in every instance. The general terms laid down for their guidance, are that "the total expenditure of each hospital on its patients is to be taken as the chief factor, in determining the share each is to receive from the Fund.' As mere expenditure, however, is no measure of its uaefulness, "the hospital most deserving of public support is that which does the most work, and does it at the least cost." The expenditure of a hospital is, after all, as *the Times* justly observes, "a good deal more easy to calculate than the work of a hospital; and since expenditure derived from endowments and realised property, is not taken into account, it is no unfair test of the general verdict of the subscribing public, and it is not easy to see in what better way the distribution could be made. On the whole, the task has been well done, and the fact furnishes not the least argument in favour of Hospital Sunday and its promoters."

RECENT REPORTS ON CHOLERA.—III.

CONDITIONS OF ITS TRANSMISSIBILITY (*concluded*).

In a former article on cholera we endeavoured to draw attention to the more important and best known conditions of the transmissibility of that disease, as illustrated by some excellent Reports that have been recently published both in this country and in the United States. The effects, however, of impure water, of the elevation of the ground, and of personal predisposition upon the prevalence, or transportation, of cholera were then but cursorily glanced at.

With regard to the influence of impure water, the investigations of Dr. Snow long ago showed what an important part this agent may play in the diffusion of cholera; and Mr. Simon, in an inquiry into the relative mortality from the disease in a district one part of which was supplied by pure and the other by impure water, found that the population drinking the foul water suffered three and a-half times as much as that drinking the pure water. Now in turning to the American Reports, we find that they furnish some striking illustrations of the power of impure water in disseminating the disease. Thus during the epidemic in Central Kentucky, "several isolated cases of cholera had occurred in the town of Lebanon near to a small creek which forms one of the drains of the town. A few days after their occurrence the Marion county fair was held upon the grounds near Lebanon. As the water supply was less than the demand the deficiency was supplied from the town. Unfortunately a well was selected on low ground and quite near to the banks of the creek. On the second day of the fair a violent rain-storm deluged the country. The creek was filled to overflowing, and it was impossible that the surface-washings should not have infected this well. On the third and fourth days of the fair the water of the well was served as usual, and on the night of the last day (August 31) cholera, malignant in its type, was developed in all localities inhabited by those who had visited the grounds and drunk the water."

As to the influence exerted by the elevation of the land above the sea level, very little can be said, inasmuch as all communities and centres of population are in towns and villages, and nearly all towns and villages are situated either by the banks of rivers, or in valleys and low-lying plains. These Reports afford abundant evidence of the fact that the most favoured seats of cholera are along the banks of rivers and in the lowest district of towns and other places, but they also incontestably show that the greater mortality from the disease observed in the latter situations is not so much owing to any difference of elevation and of barometric pressure as to the unfavourable sanitary conditions characterising, and the density and character of the population inhabiting, such districts. In many instances mentioned in the American Reports, a district which was highly favoured by Nature with respect to its elevation and surface drainage, had by the neglect

and filthy habits of its inhabitants, been converted into a hotbed of disease and pestilence. Moreover, in one instance it is well shown what danger there may be in the importation of a case of cholera, "even at a point upon a mountain, well drained, and free from all insanitary influences." Major Adair, being suddenly seized with cholera while travelling, was taken to the house of a friend, situated on one of the spurs of the Cumberland Mountains, Clinton County, Kentucky, twenty-six miles from the nearest point infected with cholera. The position of this house was so isolated that the owner first learned that cholera was in the country by the arrival of the Major. A few days afterwards—September 8th—the owner of the house was attacked with the disease, and died after a few hours' illness. On September 10th his son was taken ill, but recovered, and on the 12th his daughter was attacked with the same complaint, and died. This case not only shows that salubrity of situation is of itself no safeguard against cholera, but that the law laid down by the German physicians, and unanimously adopted by the Vienna Conference, is open to many exceptions, and that man *may* be considered as the specific cause of cholera *apart from the influence of locality*. In the above case the American reporter attributes the contagion to the fact that the dejections of Major Adair were not treated with disinfectants, but were thrown out into the privy and upon the ground. Whether the dejectione were or were not the medium by which the disease was transmitted to the other occupants of the house we will not stop to inquire, but it is pretty clear that in this instance the transmission took place quite apart from the influence of locality. It is mere sophistry to say with Pettenkofer that in such cases "the patient had conveyed with him from the cholera-district so much of the cholera poison that there was enough cholera poison to infect the other persons who were attacked."

That some persons are more susceptible to the contagion of cholera than others is a fact which is as well known as its causes are obscure. Whatever, remarks Pettenkofer, is required in addition to the specific germ (which is spread by traffic), and the local and temporal disposition (which depend on the locality), in order to produce an outbreak of cholera in the individual, is termed *individual disposition*. Whether or not the influence of locality is in itself an essential factor in the propagation of cholera is a question on which, as we have already remarked, much doubt may be reasonably entertained. No one, on the other hand, would deny that much depends upon the peculiar susceptibility of the individual. Unfortunately very little is known of the nature and conditions of this individual disposition, or indisposition, to the contagion of cholera, and as it is a subject on which our Reports are for the most part silent, we must at present dismiss it from consideration. We may, however, suggest that, in the event of another invasion of this country by cholera, there could not be a better subject for investigation than the conditions which, in respect of the constitution, habits, temperament, mode of living, and previous health of the individual, appear to predispose to the disease. It would, for instance, not only be interesting, but in a hygienic point of view, of some importance, to know if a disposition to an attack of cholera was traceable to hereditary or acquired weakness of constitution, to indulgence in intoxicating liquors, to a too full, or to a too spare habit of living, or to an habitually relaxed state of the bowels.

Notes on Current Topics.

The Antivivisection Society.

STARTING a society, or floating an association, seems to be a very peculiar business, although to the initiated it is evidently simple enough. Take for the purpose a subject temporarily occupying public attention, a home to be found for lost dogs, or Contagious Diseases Act to be repealed, women's rights to be ventilated, or a vivisection craze to be promoted, and up starts some disinterested person equal to the occasion, and who by dint of impudence and a few sensational advertisements, the thing is at once set going. The advertising columns of the daily press are open to schemers and quacks alike, and heigh presto! the thing is done, and any number of benevolent people are ready to be imposed on and fleeced; but, in the upshoot, it turns out that the greater part of the money obtained finds its way into the pockets of an individual who is nominally described as promoter or secretary of the scheme.

It now turns out, as we have before intimated, that the antivivisection society found its promoter in a Mr. Jesse, who, from what transpired last week before the Vice-Chancellor, constituted himself chairman, committee, and secretary. With but little difficulty, and with the aid of a few startling advertisements, and grossly exaggerated statements of cruelties practised by the medical profession on cats and dogs, succeeded in abstracting in a few months, several thousand pounds from the pockets of Lords and Commons. Mr. Holt, a member of Parliament, was amongst his victims, and he, in a moment of weakness, consented to allow his name to appear as the associate of Jesse, but soon discovering that this person was carrying the joke a little too far, insisted upon withdrawing himself from so questionable a position, and upon having a statement of the receipts and expenditure. This, however, proved no easy matter, for Jesse treated him and his communications with contemptuous silence, and therefore poor Mr. Holt was put to the trouble and expense of appealing to the law. The counsel who conducted the case stated, that Jesse had received about £2000 for the purposes of the society, and all attempts to make him give an account of his stewardship had proved ineffectual. The Vice-Chancellor said, "It was evident from his conduct that Mr. Jesse was a man who liked to have his own way." We should rather think so, for he still retains upwards of £1,400, and has hitherto succeeded in resisting an order of the Court made upon him in May last, positively refusing to disgorge. This Mr. Jesse, it will be remembered, forced himself before the Royal Commissioners as a witness and the representative of a society which had, it now appears, no existence.

THE will of Sir Cordy Burrows, F.R.C.S., was proved last week under a personalty of £5000.

The Debate on Vivisection in the House of Lords.

On Wednesday last, the Lords went into committee on the Vivisection Bill.

The Earl of Carnarvon stated that at the proper time he intended to propose that the title of the Bill be changed from "An Act to Prevent Cruel Experiments on Animals," to "An Act to Amend the Law relating to Cruelty to Animals." He would do so in deference to an opinion expressed by a deputation of the profession.

Clauses 1 and 2 were agreed to.

On clause 3 the Duke of Somerset called attention to the term "living animal," and thought that it should be more clearly defined, as a jelly-fish was certainly a living animal, but the law could scarcely touch a physiologist for experimenting upon a jelly-fish. Lord Kimberley could not see the use of the word living as vivisection would not be performed on a dead animal, but Lord Carnarvon considered it better that the word living should be retained as many animals, even with the head cut off, showed signs of sensation.

Lord Rayleigh proposed as an amendment on the clause to strike out the words restricting vivisection to experiments for the saving or prolonging human life or alleviating human suffering, and insert words permitting of vivisection for the advancement of medical or physiological knowledge.

The amendment was strongly opposed by Lord Coleridge, whose illogical arguments are worthy of note. He said "We do not know what the lives of the lower animals really are, we cannot describe their interests, whether they have or have not any glimmer of the light of reason, whether they have any share of responsibility imposed upon them, we do not know. Some persons say that they have no feeling in the sense that we have feeling, because they have no reflection and no foresight. But I know, on the other hand, that whether they perish altogether seemed to so great a man as Bishop Butler very far from clear; and to my mind it is extremely doubtful whether we have the moral right which is asserted, and which underlies the whole of this discussion, to put them to torture, even if it turns out for our benefit."

In the same breath he says, a short time since, slaves were as mere chattels, yet no man would dare to suggest that it is morally lawful to put to torture persons of that condition, even though by so doing we can prolong the life or mitigate the sufferings of a superior race.

If Lord Coleridge expects to meet lower animals in a future world, his objections to vivisecting them in this world may be excused.

Thus he reasons, because we would not perform vivisection experiments on slaves—who we may recall to his mind are human beings—surely we have no right to do so on cats and dogs, &c., animals more tied to man by friendship than slaves, to be consistent he must at the same time raise his voice against them being killed for food. For ourselves we should not take the life of a lower animal into consideration where that of a man was concerned, and slaves we should class as men, but we would refuse to receive into our society any individual who would inflict pain *unnecessarily* upon any creature.

Lord Cardwell had given notice of an amendment almost identical with that moved by Lord Rayleigh, and the Bishop of Peterborough supported Lord Cardwell's amendment, on the ground that it would check the continuance for mere purposes of instruction of experiments on living animals in reference to physiological facts and phenomena which had already been settled. The amendment was agreed to.

The Earl of Lansdowne drew attention to the next subsection, which provided that the places in which experiments were made should be registered. The effect of the provision would be to limit and obstruct useful and beneficial discoveries.

Lord Kimberley regarded the limitation as an outrage on the learned professions affected by it.

The Lord Chancellor said if they did not register the place in which vivisection was to be done, inspection could not be made, and the Bill might as well be given up altogether. If the restriction to a licensed place were retained, there would be a protection offered by the licensed place, but if the restricting clause were removed, the Secretary of State in granting the license for vivisection, must rely on the character of the person applying for the license, and would be inclined to grant licences to those only who were known to be men of honour. In this way the removal of the restricting clause would be the worst possible thing for the medical profession.

The Earl of Carnarvon spoke to the same effect, adding that the worst cases of abuse had occurred not in public institutions, but in private lodgings. It was suggested by the Lord Chancellor that as inconvenience might arise if experimentation with drugs were required to be made at licensed places, words might be added in another part of the Bill to the effect, that any person holding a license under the Act, might, in any place licensed or not, administer drugs to animals for the purpose of ascertaining the effect.

The sub-section restricting vivisection to licensed places was ordered to stand part of the clause, and the clause to stand part of the Bill.

Clause 4 provides that the substance known as urari or curari shall not for the purposes of the Act be deemed to be an anæsthetic.

This clause was agreed to.

The Earl of Harrowby moved, that the horse, ass, or mule, should be classed with the cat and dog, on which experiments should not be performed.

This amendment likewise was agreed to.

It was afterwards proposed by the Earl of Carnarvon to amend the clause by inserting after the words dog, cat, horse, ass, or mule, the following words;—

Except in such certificates being given as in this Act mentioned, and that for reasons specified in such certificates, and where the object of an experiment would be necessarily frustrated unless made on an animal similar in constitution to a dog or a cat, &c., &c., and no other animal is available for the experiment. The addition of his words will be again brought forward on the report.

The clause was therefore agreed to as also clauses 6, 7, 8, 9, 10.

On clause 11 some discussion took place upon the addition of the names of certain scientific bodies who may give certificates for the making of experiments. The clause as it stands was ultimately added to the Bill as also the remaining clauses.

The Shower of Flesh.

THE reports that reached us from America some months ago of the descent of a shower of flesh in Kentucky—probably the *débris* of a monster explosion some hundreds of miles away—have received elucidation by Mr. Brandeis in the *Sanitarian* for May last. It appears that in 1537, while Paracelsus was engaged in the production of his "elixir of life," he came across a very strange looking vegetable mass, to which he gave the name of "Nostoc."

The want of rapid transportation, combined with the perishable nature of the substances fallen, have hitherto prevented a complete and exhaustive examination. The specimens of the "Kentucky shower" were well preserved in glycerine, and it has been comparatively easy to identify the substance and fix its status. The "Kentucky wonder" is nothing more or less than the "Nostoc" of the old alchemist. The Nostoc belongs to the confervæ; it consists of translucent, gelatinous bodies, joined together by threadlike tubes or seed-bearers. There are about fifty species of this singular plant classified; two or three kinds have even been found in a fossil state. Like other confervæ, the Nostoc propagates by self-division as well as by seeds or spores. When these spores work their way out of the gelatinous envelope they may be wafted by the winds here and there, and they may be carried great distances.

Wherever they may fall and find congenial soil, viz., dampness or recent rain, they will thrive and spread very rapidly, and many cases are recorded where they have covered miles of ground in a very few hours with long strings of Nostoc.

On account of this rapidity of growth people almost everywhere faithfully believe the Nostoc to fall from the clouds, and ascribe to it many mysterious virtues. In New Zealand it is found in large masses of quaking jelly several feet in circumference, and covering miles of damp soil.

All the Nostocs are composed of a semi-liquid cellulose and vegetable proteine. The edible Nostoc is highly valued in China, where it forms an essential ingredient of the edible bird-nest soup. The flesh that was supposed to have fallen from the clouds in Kentucky is the flesh-coloured Nostoc (*N. carneum* of the botanist); the flavour of it approaches frog or spring chicken legs, and it is greedily devoured by almost all domestic animals.

Norwegian Lepra.

DR. NEUMANN, of Vienna, has published in the *Allg. Wien. Med. Zeit.* (March 7th, 1876) an article on the etiology of this disease. Authors are not quite agreed whether it is hereditary or not; but it would appear that it is contagious. Low lands on the coast and bad food and shelter have much to do with the appearance of the disease in both hemispheres. The prognosis is generally very bad; the patients mostly perish of marasmus, pneumonia, phthisis, albuminuria, &c. The author makes a statement which, at least, as regards Scotland, would require confirmation. He says that in Norway the vas deferens of boys affected with lepra is tied, to arrest procreation, and that in *Scotland* castration is performed upon leprous lads for the same purpose.

The Profession and Quackery.

THE President of the Sacramento Medical Society, in his annual address, published in the *Pacific Medical and Surgical Journals*, discussing the claims of the profession, says:—"'It is the duty of physicians, who are frequent witnesses of enormities committed by quackery, and the injury to health and even destruction of life caused by the use of quack medicines, to enlighten the public on these subjects, to expose the injuries sustained by the unwary from the devices and pretensions of artful empirics and impostors. Physicians ought to use all the influence which they may possess as professors in colleges of pharmacy, and by exercising their option in regard to the shops to which their prescriptions are sent, to discourage druggists and apothecaries from vending quack or secret medicines, or from being in any way engaged in their manufacture or sale. Physicians are seldom found backward or unwilling in the performance of these duties to the public. Although it would appear to be against their own pecuniary interests to preserve the public health, yet it is notoriously true that they are ever vigilant in this labour of love."

Hospital Saturday Fund.

LAST week the fourth meeting of the board of delegates for the current year was held at the Metropolitan Convalescent Institution, Walton-on-Thames. After some routine business had been transacted, the Chairman, Captain Mercier, reported that Mr. Hally, the organising agent, had visited the employés of nearly 1,000 large firms who did not contribute to the fund last year, and had obtained the co-operation of nearly all, having succeeded in placing a very large number of the weekly collection sheets—amongst these firms were many who had subscribed in the first year, but had not last; that active preparations were being made in the office for the issue of collection sheets to domestic servants and tradesmen, and it was expected that these would result in a very large return to the revenue of the fund. The rest of the report consisted of routine matter. In conclusion the Chairman said it was a great gratification to him to be able to show the members another instance of the great progress the movement was making. This was a *bon-mot* which appeared in last week's *Punch*, in the following words, viz., "The best lifts for Hospitals, Hospital Saturday and Hospital Sunday."

Homœopathic Advertisements in Medical Journals.

WE observe that a contemporary acknowledges the receipt of a copy of the correspondence between a member of the profession and the proprietors of a monthly journal of therapeutics, respecting the publication of advertisements of the London Homœopathic Hospital and the courses of lectures to be delivered there. We feel convinced, says our contemporary, that the proprietors in question need only to be again reminded of the strong feelings entertained by the medical practitioners of this country on the subject of homœopathy, to discontinue their encouragement of the homœopathists and their doctrines. Those who are able to refer to our past utterances upon homœopathic principles will scarcely suspect us of coquetting with that form of quack-

ing, yet we feel that there is no more powerful stimulus to infinitesimalism than that derived from unreasonable treatment on the part of the profession. Homœopathic advertisements published in the columns of a medical journal, may be accepted as *ex parte* statements made to a well-informed audience. Their insertion does not pledge the journal in whose columns they appear to any approval of them, and will not—in the remotest degree—recommend them to the credulity or approval of readers. We cannot see that there is any infraction of professional etiquette in the insertion of such advertisements which amount to nothing more than announcements which—we confess—seem to us thrown away upon medical constituencies. It is too late for medical journals to taboo such advertisements when they have—after warning—advertised, each week for long periods, the sale of sham diplomas in London.

Milk of Sulphur.

We regret to observe the *Lancet* engaged upon an apology for the "milk of sulphur" fraud. "People who want pure sulphur," our contemporary says, "can always, it appears, get it by exercising due care." We would be glad to know how "due care" is to be exercised. Is it by purchasing Macnamara or Pereira, and reading up the subject? or is it by a plain, honest description on the label? If the latter, we cordially agree with *Lancet*. If the former, we protest against a materia-medica education being expected from the uninstructed public.

A Foul Spot.

"How are we to dispose of our town refuse?" is a question as often askedas "What are we to do with our sewage?" Certainly it is of almost equal importance in large towns. There is no difficulty in the disposition of cinders, rags, and the ordinary contents of dustbins; but when we come to think of the thousands of dead cats and dogs, the tons of fish, garbage, condemned meat from the markets, and the sweepings of the streets, we often wonder what becomes of it all. We are not, however, left long in the dark, as the Vestry of Islington unvitalised itself on Saturday by explaining *what it did* in the matter, and how "the cheap and nasty business" had prompted its action.

The said vestry was represented by Mr. John Layton, vestry clerk and solicitor, of Islington, the summons being taken under the provisions of the Nuisances Removal Act, for allowing a nuisance to exist at the rear of the houses in Ashburton Grove, Islington.—Mr. Rickets, solicitor, represented the complainant, who was an inhabitant of that parish. In opening the case he remarked that the magistrate might be surprised to find that the vestry, who were supposed to be the guardians of the public health, were now themselves committing as abominable a nuisance as ever was committed, and had the hardihood to attend the court to defend their proceedings. The nuisance complained of arose from an immense deposit of decayed and decaying animal and vegetable matter on a large piece of enclosed land, about three acres in extent, in a populous part of the parish of Islington—viz., on a piece of land between Ashburton Grove and Queensland Road. This plot abutted on a thickly populated district, and the houses forming one side of Ashburton Grove were only divided from it by a low fence, and the small back gardens of the houses. In the month of March last the Vestry of Islington took this land from the Great Northern Railway Company, and had made of it a shoot for all the refuse of their parish, and thousands of loads of rotten fish, fish entrails, decayed animal and vegetable matte, including dead dogs and cats, besides the ordinary contents of dust-holes, were deposited there. Some of this refuse was thrown up into embankments for the purpose of forming bays into which the liquid slop from the parish roads was emptied. This huge mass emitted the foulest smell, and polluted the atmosphere for a considerable area. Between 2000 and 3000 loads of this abominable mixture were now lying in a heated and festering state under the very noses of these poor people, who had petitioned the vestry, and who he was sorry to say, had petitioned in vain—to do away with this nuisance, but the vestry carts still continued to empty their foul contents on this land. The only object to be served by not taking away the parish refuse into the country was something like a saving of 4s. per load, which he (Mr. Ricketts) was instructed the vestry declined to pay, but the public health ought not to be sacrificed on the ground of saving expense. In conclusion, he had to ask that the case might be remitted to the quarter sessions for trial.—Mr. William Irish, a carpenter, residing at Ashburton House, Ashburton Grove, Islington, gave a description of the objectionable heaps. A school was close to them, and the playground, in which upwards of 100 children disported themselves, directly bordered upon them. He had continually noticed that a cloud like a fog rose morning and evening over those heaps, and the stench was quite overpowering. When the wind blew in the direction of his house he was compelled to have all his windows and doors closed because of the foulness of the smell. The parish authorities did not use any disinfectants at that spot, and none were ever employed by them. He had signed the memorial to the vestry, asking that the nuisance might be removed or abated, and he had seen many others sign it, but no notice had been taken of the complaint. Since the hot weather innumerable flies had collected, and the heaps were all covered with flies.—Mr. James Glover, surgeon, of Islington, said he knew the piece of land in question, and that morning had seen it. There was a large deposit of material, including putrid animal and vegetable matter, which was full of flies. The smell was very bad, and it had but a superficial covering of ash and dirt. In his opinion the deposit was likely to be a nuisance, and injurious to the health of the persons residing in the neighbourhood, in fact, to the whole parish.—The magistrate said that it was a case that he should, in all probability, have to send for trial, and adjourned the summons for a week.

On Friday last, another victim to the accident at St. George's Hospital died from the effects of injuries received.

Dr. Brewer, chairman, and the members of the Metropolitan Asylum Board, paid their annual visit of inspection on Saturday to the Leavesden Imbecile Asylum, which contains no less than 2,100 inmates, everything was found to be in a most satisfactory state.

Owens College and the Royal Infirmary, Manchester, are about to come into possession of a magnificent legacy. Mr. C. F. Beyer, a wealthy Manchester merchant, has recently died, leaving his interest in the Gorton Locomotive works, which is expected to realise nearly a quarter of a million, to these institutions.

The sanitary authorities at Greenock complain that they are unable to subdue scarlet fever in the town, in consequence of the obstinate recklessness of parents, who allow their children to mix freely with others from infected houses, and will neither themselves disinfect clothes and bedding nor allow the authorities to do it for them.

THE grant of a Civil List Pension to Dr. Rumsey, of Cheltenham, which has just been announced, is an act worthy of a discriminating Government. Not a medical man has devoted himself with more unselfishness or with more untiring energy to the advancement of hygienic science and the improvement of sanitary law than Dr. Rumsey, and it is in consequence of his over-exertion in this field of labour that he has—by sickness—been obliged to accept the aid of the State.

THERE has recently been discovered at the Louvre the real portrait of the great anatomist, André Vesale, known by the famous engraving of "The Lesson in Anatomy." It is the work of Jean Calcar, the designer of the anatomical plates of Vesale. The illustrious surgeon is represented at the age of 26, leaning on a column. On a ring on a finger of his left hand the following inscription has been made out:—"A. V. B. Andreas Vesalnus Bruxelliensis," clearly establishing the authenticity of the picture.

Correspondence.

ON SUPPORT OF THE PERINEUM.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Writers on midwifery have, of late years, generally speaking advocated the supporting of the perineum, but still among them there is a considerable difference of opinion as to the amount of support, when it should commence, and how long it should continue.

Dr. Ramsbotham says, it should be firm and continuous from the time the head commences to press. Dr. Churchill recommends, very gentle and careful support, and says he has seen cases of rupture of the perineum where it has been excessive and injudicious; Dr. Denman approves of it, only in first cases, while Dr. Leishman goes so far as to say that it is quite useless, and looks upon it as a relic of "meddlesome midwifery."

When I first commenced practice, I considered it was my duty to begin supporting the perineum as soon as ever the child's head began to press. I very soon found out that this was neither necessary or advisable. Since then, I have attended about 1,800 cases of labour, and I don't remember seeing a serious and complete rupture of the perineum, except in one instance, and that was a forceps case in a woman not very young, and in her first confinement; undoubtedly, there were some slight lacerations of the fourchette, which are generally admitted to occur very often in first cases. I have known many instances of women in labour, who had no assistance, except that afforded by some old women who knew nothing about supporting the perineum, and still no laceration occurred.

From this, I would feel inclined to agree with the statement that "the practitioner who never puts his hand to the perineum will have fewer cases of its rupture than he who admits support as applicable to every case from the time the head is pressing." At any rate, I consider that it is rarely, if ever necessary to support the perineum until the head of the child is about to pass the vulva, this is the only time it can be of any service; it is useless to commence it sooner, and it must be positively injurious, as the pressure of the hand, if long continued, heats and inflames the perineum, and if very firm by keeping back the head delays its expansion, and wastes the force exerted by the uterus to expel the child, and so, instead of assisting labour, retards it. I have thought that a small sheet, say about four inches square of vulcanised india-rubber, or some such elastic substance, applied evenly over the perineum by the palm of the hand would be a more satisfactory way of giving support when necessary, and I intend to give it a trial.

W. L.

FRENCH BATHING PLACES—BOULOGNE-SUR-MER.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—This little island of ours is so small that, whenever the summer weather becomes genial enough to make travelling agreeable, it is the custom for crowds of British subjects to seek the bathing places of the French Coast, overflowing as it were, from the many charming sea-side resorts of the South Coast.

Boulogne-sur-Mêr is one of the most attractive, gay and pleasant, as well as the most accessible of all French watering places. Its sands are splendid; its bathing regulations excellent: and its casino and theatre quite admirably managed. Probably no English seaside resort presents greater *distractions* than Boulogne.

A year or two ago, however, I had the privilege of calling the attention of yourself and readers in the MEDICAL PRESS AND CIRCULAR to the defective way in which the contents of the drains in Boulogne are conveyed to the sea.

I naturally thought, that it only required that this weak side of Boulogne-sur-Mêr should be alluded to in a medical journal, in order that steps should be taken by the enlightened municipality of that town to put an end to the evil. Has not the town council of Boulogne evinced its respect for hygiene, by erecting a statue to the illustrious Edward Jenner?

Well, no! I happened to be in Boulogne in the month of May and found that the plan of emptying all the sewers of the town into the river still continues, so that, at low water, the effluvia is most unpleasant and unwholesome. Perhaps Mr. Sidney Chater, my former colleague in the Metropolitan Free Hospital, now resident in Boulogne, can explain to us why it is that the wise men of Boulogne-sur-Mêr, who are contemplating the turning of their fair town into a second Marseilles, should be so supine in the matter of health: and whether there may not be some more insuperable difficulties than I can appreciate, in carrying the sewage of Boulogne far away to the sea.

I remain, Sir, yours faithfully,

C. R. DRYSDALE, M.D.

17 Woburn Place, London, W.C., June 15, 1876.

BRITISH MEDICAL ASSOCIATION.—The Annual Meeting will be held at Sheffield on Tuesday, Wednesday, Thursday, and Friday, August 1st, 2nd, 3rd, and 4th, 1876.

President.—Sir Robert Christison, Bart., M.D., D.C.L., LL.D., F.R.S.Ed.

An Address in Medicine will be given by E. H. Sieveking, M.D., F.R.C.P., Physician-Extraordinary to the Queen.

An Address in Surgery will be given by W. F. Favell, Esq., Surgeon to the General Infirmary, Sheffield.

An Address in Public Medicine will be given by Alfred Carpenter, M.D., Croydon.

Local Secretaries.

Arthur Jackson, Esq., St. James's Row, Sheffield.

J. H. Keeling, M.D., 267 Glossop Road, Sheffield.

Tuesday, August 1st.

1 P.M.—Meeting of Committee of Council.

3 P.M.—Meeting of Council, 1875-76.

8 P.M.—General Meeting.—President's Address; Annual Report of Council; and other business.

Wednesday, August 2nd.

9.30 A.M.—Meeting of Council, 1876-77.

11.30 A.M.—Second General Meeting.

11.30 A.M.—Address in Medicine.

2 to 5 P.M.—Sectional Meetings.

9 A.M.—Soirée.—Weston Park Museum.

Thursday, August 3rd.

9 A.M.—Meeting of Committee of Council.

10 A.M.—Third General Meeting.—Reports of Committees.

11 A.M.—Address in Surgery.

2 to 5 P.M.—Sectional Meetings.
6.30 P.M.—Public Dinner.

Friday, August 4th.

10 A.M.—Address in Public Medicine.
11 A.M.—Sectional Meetings.
1.30 P.M.—Concluding General Meeting.—Reports of Committees, &c.
Promenade Concert at the Albert Hall.—Visits to the Works.

Saturday, August 5th.

EXCURSIONS.—Chatsworth, Wentworth, Wharncliffe, and other places.

Mr. Lawson Tait (Birmingham) gives notice that he will move at the annual meeting in August next the following alterations in and additions to the By-laws.

1. That By-law 8 read thus : "That the President shall be elected every year at the last general meeting from among the members resident in the district in which the next annual meeting is to be held, and he shall enter, etc." ; and further to read as it now stands.
2. That By-law 12 shall read : "That the Editor of the Journal shall be subject to annual election at a general meeting of the members of the Association ; that he shall be remunerated as the Committee of Council see fit ; and that he shall be responsible for all that appears in the Journal."
3. That By-law 13 shall read : "The Secretary of the Association shall be subject to annual election at a general meeting of the members of the Association ;" and further as it now stands.
4. That a By-law shall be inserted to the effect that "The Journal shall be considered the organ of communication between the members of the Association ; and that no reasonable communication from any member or members shall be refused admission, without the reason for such refusal being communicated to such member or members."

FRANCIS FOWKE, General Secretary.
36 Great Queen Street, London, June 8th, 1876.

UNIVERSITY OF DUBLIN.—MEETING OF THE SENATE.

THE Senate of the University of Dublin met at two o'clock last Saturday. The Right Hon. Sir Joseph Napier, Bart., Vice-Chancellor, presided.

Honorary Degrees.—Rev. William Roberts, F.T.C., as Senior Proctor, moved that an honorary degree of M.D. be bestowed upon our distinguished Professor of Chemistry, James Emerson Reynolds, a gentleman who, he said, had given ample proofs of his originality and industry in the field of scientific research. He might refer to Mr. Reynolds' important discovery of sulphur urea and his paper on silicates; and if it were true that *les bon elves font la gloire du maitre* he had another high claim to the distinction they proposed to confer upon him, in the list of his pupils who had obtained the highest honours that were conferred in this University for proficiency in chemical science. Mr. Williams also proposed that the honorary degree of Master in Engineering on Mr. Howard Grubb, who, he said, had devoted himself with singular zeal and success to the improvement of optical instrumeuts, and had supplied many such to foreign observatories—thus gaining for himself a well-earned reputation and conferring honour on his country.

The Rev. Dr. Haughton said it should be noted that Mr. Grubb owed his training to Trinity College. He was one of the pupils in the engineering school, and during his collegiate career obtained high distinctions. Although they could not have claimed to have trained him in the speciality in which he distinguished himself, he laid the foundation of his knowledge here.

The degrees were unanimously voted.

Degree of Licentiate in Midwifery.—The Rev. W. Roberts submitted the following statutes :—

DE GRADIBUS ET LICENTIIS IN ARTE OBSTETRICIA CONFERENDIS.

Ad Magisterium in Arte Obstetriciâ ii tantum admittantur qui prius in Medicinâ et in Chirurgiâ graduati fuerint, et qui duos ad minimum annos in studio Artis Obstetriciæ compleverint, secundum regulas a Præposito et Sociis Senioribus præscriptas vel præscribendas.

Priusquam gratia proponatur, Candidatus a Professoribus in Scholâ Midicinæ publice solenniter examinetur et idoneus comperiatur.

Statutum est etiam quod in praxin Artis Obstetriciæ ii admittantur qui in praxin Medicinæ atque Chirurgiæ prius admissi fuerint, et qui duos ad minimum annos in studio Artis Obstetriciæ compleverint atque examinationem sustinuerint, secundum regulas a Præposito et Sociis Senioribus præscriptas vel præscribendas.

Nemo autem admittatur nisi gratia Præpositi et Sociorum Seniorum pro Gradu vel Licentia prius concessa fuerit.

ARMY MEDICAL OFFICERS.

IN the House of Commons yesterday, replying to a question of Dr. Ward, Mr. Gathorne Hardy, Minister for War, said that the arrangement by which, under the warrant of 1873, medical officers were attached to regiments for five years, had been abolished, and the medical officers had been placed in a general rota, in accordance with which those who had served at home longest would be sent abroad first. Those about to be sent on foreign service had not served out of this country for fifteen years.

Medical News.

Royal College of Surgeons of England.—The following Members were elected Fellows of the College at the last meeting of the Council—viz.,

Jennings, Joseph C. S. (M.R.C.S. 1841), Malmesbury, Wilts.
Whitehouse, Edward O. W. (M.R.C.S. 1840), Thurlow Road, Hampstead.

Cambridge University.—At the Congregation on June 15th the following degrees were conferred :—

Doctors of Medicine.

Buck, William Elgar, St. John's College.
Lees, Daniel Bridge, Trinity College.
Moore, Norman, St. Catharine's College.

Bachelors of Medicine.

Barron, Thomas Walter, Caius College.
Smith, Charles Callow, Christ's College.

ON THE ADMINISTRATION OF SULPHUROUS ACID IN ENTERIC FEVER.

DR. J. W. BOTKIN, of Morrisonville, Ill. (*Medical and Surgical Reporter*, May 13th, 1876), writes strongly in favour of the use of sulphurous acid in the treatment of enteric fever, and gives the particulars of several interesting and instructive cases in which its administration was attended by very marked benefit. His attention was first directed to the advantages of this remedy by an article in

Braithwaite's *Retrospect*, from the pen of Dr. G. Wilks. The first case in which he tried acid was as follows: A gardener, æt. 65, ill several days before being seen, alarmingly prostrate both physically and mentally, vomiting and purging, with the abdomen tympanitic and painful to the touch, and distinct gurgling about the ileo-cæcal valve on palpation. The pulse was 125, and alarmingly feeble. The tongue was covered with a dark brown coat through the centre, the tip and edges being red and dry as an oven. There was considerable bleeding at the nose and the eruption was plainly visible. In 18 hours after use of the acid "the vomiting had ceased, the purging was controlled, the tympanitis was much reduced, the feeble pulse was growing stronger, and the parched tongue was moister and the thirst less. He was now able to take the nourishment ordered, which consisted principally of milk and brandy, and the whole aspect of the case was decidedly hopeful. He continued to improve, and in one week was discharged."

Dr. Batkin claims for the acid that "it acts as a specific upon the fever poison, arresting the further development of that poison, and by controlling the arrest long enough, exterminates the fever. In a word, *it is an antidote.*"

He treated thirty cases during a period of eighteen months, and only lost one patient, a fragile girl whose life was gradually wasting away with consumption, but who recovered, then took a relapse and died.

He usually prescribes the acid in lemonade, giving from three to fifteen drops every four hours, and continues it until the tongue is perfectly clean.

When the discharges are very troublesome, the pulse high, and the skin dry and hot, he adds opium, verat. vir., and nitre, according to the age of the patient. In almost all the cases where the acid was omitted too soon a relapse occurred.

NOTICES TO CORRESPONDENTS.

☞ Correspondents requiring a reply in this column are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

Reading Cases.—Cloth board cases, gilt-lettered, containing 26 strings for holding each volume of the Medical Press and Circular, can now be had at either office of this Journal, price 2s. 6d. The postal regulations not allowing the Journal to be stitched, these cases will be found very useful to keep each weekly number intact, clean, and flat, after it has passed through the post.

F.R.C.S.—Your communication shall appear in our next.

A Dental Surgeon.—Declined, with thanks.

Mr. R. Hanslip Sers' communication shall appear in an early number.

Mr. Jenner.—1. The best work in the English language is "Parrish's Pharmacy." 2. A question the *Pharmaceutical Journal* or the *Chemist and Druggist* are in a better position to answer than we.

The Index for the past volume will be given in our next.

Dr. L.—We have received the local paper, but not being acquainted with the facts of the case, we are unable to pass an opinion. Should there exist any published reports giving both sides of the question, and you will forward them to us, we shall be happy to notice it on its merits.

Dr. M. J. Malone.—Your communication on "Unusual Sequels of Scarlet Fever" will appear in an early number.

Dr. Mapother.—Communication received too late for insertion in the present number. Proofs will be sent in due course.

BOOKS, PAMPHLETS, AND MEDICAL JOURNALS RECEIVED.

On the Wire Ligature in Ununited Fractures. By W. A. Byrd. Quincy, Illinois.

Memoires sur la Galvano-caustique Thermique. Par le Dr. A. Amussat. Paris: Baillière.

Des Sondes a Demeure et du Conducteur en Balaine. Par le Dr. A. Amussat. Paris: Baillière.

The Physiology of Mind. By Hy. Maudsley, M.D. London: Macmillan and Co.

VACANCIES.

Owen's College, Manchester.—Demonstrator and Assistant Lecturer on Anatomy. Salary, £100 per annum. Applications, under cover, to the Registrar.

Downpatrick District Lunatic Asylum. Assistant Resident Medical Superintendent. Salary, £100, with board, &c. (See Advt.)

Hospital for Sick Children, Great Ormond Street, W.C. Third Assistant-Surgeon. Honorary. Candidates must be Fellows of the College of Surgeons of England.

Hants Lunatic Asylum, Knowle. Two Assistant Medical Officers. Salary of Senior, £150; Junior, £100, with board. Address Dr. Manley, Knowle, Hants.

Ipswich Asylum. Assistant Medical Officer. Salary £100, with board. Apply to the Medical Superintendent.

Brighton Hospital for Sick Children. Two Acting Surgeons. Full information of the Resident Secretary.

Royal Asylum of St. Anne's Society, Streatham. Consulting Physician. Honorary. Applications to the Council.

APPOINTMENTS.

Best, G. P., B.A., M.R.C.S.E., a Resident Clinical Assistant to the Hospital for Consumption and Diseases of the Chest, Brompton.

Bowes, J. I., M.R.C.S.E., Assistant Medical Officer to the Northamptonshire Lunatic Asylum, Berry Wood.

Davies, N. E., L.R.C.P.L., M.R.C.S.E., a Medical Officer to the Yeatman Hospital, Sherborne.

Davison, F. V., M.B., a House-Surgeon to the Royal Infirmary, Liverpool.

Dean, O., M.R.C.S.E., L.S.A.L., Medical Officer for the United Districts of St. Andrew and St. Jude, Manchester.

Gambie, Dr. C. L., Medical Officer and Public Vaccinator for the Parish of Aberdour, Aberdeenshire.

Gill, S. A., L.R.C.P.Ed., L.F.P.S.G., Medical Superintendent of the Royal Lunatic Hospital, Liverpool.

Gillibrand, W., L.K.Q.C.P.I., L.M., a House-Physician to the Royal Infirmary, Liverpool.

Gorst, H., M.R.C.S., a House-Physician to the Royal Infirmary, Liverpool.

Harris, A. B., M.D., L.R.C.P.Ed., M.R.C.S.E., Medical Officer and Public Vaccinator for the Constantine District of the Falmouth Union.

Jones, J. M., L.R.C.P., a House-Surgeon to the Royal Infirmary, Liverpool.

Lloyd, J. H., M.R.C.S., House-Surgeon to the Tiverton Infirmary and Dispensary.

Maccall, W. N., M.D., C.M., Honorary Surgeon to the Clinical Hospital and Dispensary for Children, Manchester.

Mahomed, F. H. H. A., M.D., M.R.C.P.L., an Assistant-Physician to the London Fever Hospital.

Noad, G. W., M.D., M.R.C.S.E., Medical Officer for the Wokingham District and the Workhouse of the Wokingham Union.

O'Connor, L., L.R.C.S.I., L.K.Q.C.P.I. & L.M., Medical Officer, &c., for the Glenarm Dispensary District of the Larne Union, co. Antrim.

Orpen, A. H., L.R.C.S.Ed., L.K.Q.C.P.I., Medical Officer for No. 1 District of the Chelmsford Union.

Pollock, N., M.D., Medical Officer, &c., for the Barronstown Dispensary District of the Dundalk Union, co. Louth.

Reede, S. T., L.R.C.S.I., L.K.Q.C.P.I., Medical Attendant to the Carrickmacross Fever Hospital.

Savory, W. S., F.R.C.S., Consulting-Surgeon to the London Fever Hospital.

Turner, F. C., M.B., M.R.C.P.L., an Assistant-Physician to the London Hospital.

Will, J. C. Ogilvie, M.D., Surgeon to and Lecturer on Clinical Surgery at the Aberdeen Royal Infirmary.

Marriage.

Walsh—Dudgeon.—On the 14th inst., in Dublin, by special license, Charles J. Walsh, M.D., of Castlebar, to Janet Ritchie, youngest daughter of the late John Dudgeon, also of Castlebar.

Parrott—Norman.—On the 24th of June, at Denham Church, Bucks, Edward J. Parrott, M.R.C.S., of Hayes, Middlesex, to Emma, second daughter of James Norman, Esq., of Southlands, Denham.

Deaths.

Edwards.—On the 18th of June, at Burnley, Lancashire, William Edwards, M.D., aged 58.

Goldwyer.—On the 12th of June, at Clifton, Bristol, William Goldwyer, M.R.C.S.E., aged 78.

Heath.—On the 13th of June, at Chorlton-on-Medlock, Ashton Marler Heath, M.R.C.S.E., aged 73.

Kelland.—On the 15th of June, at Poplar, Charles Theophilus Kelland, M.R.C.S.E., aged 40.

Kittermaster.—On the 18th of June, at Meriden, Warwickshire, James Kittermaster, M.D., aged 87.

Kittson.—On the 14th of June, at Wellington Road, Dublin, Edward John Kittson, L.K.Q.C.P.I., of Nenagh, co. Tipperary, aged 28.

Lloyd.—On the 20th of June, at St. Leonard's-on-Sea, in the sixty-eighth year of his age, Thomas Lloyd, M.D.

Merry.—On the 20th of June, at Marlowes House, Hemel Hempstead, Herts, Robert Merry, M.D., F.R.C.S.E., aged 66.

Ochiltree.—On the 5th of June, at Earsdon, Northumberland, Charles William Ochiltree, M.R.C.S.E., aged 53.

Ogilvie.—On the 12th of June, at Lime Grove, Shepherd's Bush, Alexander Ogilvie, Surgeon, aged 74.

Steel.—On the 11th of June, at Stafford, John Shaw Steel, M.D., aged 53.

White.—On the 16th of June, at the residence of his son (Dr. Wm. Dudley White, 58 Blessington Street, Dublin), William White, Esq., City Coroner, in his 65th year.
